Your correspondent also remarks, "How it was Mr. Sturtevant lost nineteen hives out of twenty is not clearly stated." As the passage is most interesting as bearing on the point at issue I will quote in its entirety:—"No extremity of cold that we ever have in this climate will injure bees if their breath is allowed to pass off so that they are dry. I never lost a good stock that was dry and had plenty of honey. In the winter of 1856-6 I had twenty stocks standing in a row, all but one of which would have been regarded as in a good condition for wintering—not too tight below nor yet too open above. One was in a hive suspended 20 inches from the ground and without any bottom board. The chamber for surplus honey boxes was open to the north, and had eight 1-inch holes all uncovered. I left home about the 12th of February, the weather being very cold and the hives all banked up with drifted snow. Returning the last of the month I examined the whole row and found the nineteen thawed out, but in a sadly wet and miserable plight. If I could have taken them into a room out of the reach of the frost until they were dry they might have been saved. The weather changed to severe freezing before the next morning, and all the nineteen swarms soon died, while the one that was apparently so neglected came out strong and healthy. Before adopting upward ventilation I had lost my best swarms in this way until I became discouraged."

Mr. Pettigrew, with very possibly little experience of the habits of bees taking up their quarters in roofs of houses, and showing their predilection for a shaded or north aspect to there obtain, as I suggested, the most thorough dormancy with the consequent minimum consumption of honey. For his information I ought more fully to have explained that their so settling was not a mere fancy of mine or haphazard procedure. On the contrary, we never had a swarm come before its approach was heralded for several days by a daily increasing body of scouts, which selected and cleaned out the compartment, and with the first burst of good swarming weather the swarm duly arrived to occupy the selected site.

That bees prefer a rather shaded position to one exposed to the full blaze of hot sunshine is a well-known fact. In my novitiate days my old preceptor foolishly taught me to hive my swarms and leave them till the evening. On how many occasions did I find nothing but the empty hive to remove! whereas on more than one occasion have I found swarms alighting within the shade of an old tree unobserved work large comb cakes attached to the branch on which they settled, and maintain their position till their works were destroyed by heavy rains, leading to their discovery.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

GOLDEN HAMBURGS (F. R.).—It will be unfair to expect as many eggs from birds in confinement as from those that are at liberty. We should

have been glad if you had given us the dimensions of the place in which the Hamburgs are confined and the nature of the run, whether it is hard gravel or plain earth. It is yet early for fowls to begin laying, and if in confinement they must be provided artificially with such food as they would pick up if at liberty. Green food, lettuces now and then, a swede or a carrot, but above all some good large sods of growing grass cut with plenty of earth; an occasional basket of road grit and some bricklayers' rubbish. Cleanliness, as it is understood by sweeping the ground of a run till it presents an even and spotless surface, is detrimental to poultry; they want something to scratch in and to search for—one of the many little adjuncts to health of which we know nothing, but which Nature teaches them to find. You will consider our answer full of generalities, but they bear on the question. Pullets lay when they arrive at the proper age; hens lay in the natural season. Your Hamburgs were pullets last year, and are hens now, and subject to the universal law. Are you sure they do not lay and eat their eggs? Fowls in confinement often do, especially if the eggs are suffered to lie about. Your time of dearth has been the winter, when eggs are very scarce, and have been this year unusually so. Your food is judicious, but substitute ground oats for sharps. If you provide the helps we have named your Hamburgs will now lay regularly, beginning in about a fortnight. We imagine the Brahmas and Dorkings are pullets. The four Dark Brahmas hens will not, perhaps, lay for another month because they are hens, but we cannot understand that the Light Brahmas do not lay at their age. It is against nature. We believe they lay. The eggs are eaten or they do not reach you. You say they are fed on meal in the morning and grain at two o'clock. If that is all the feeding they have it is not enough. They should be fed at this time of year at 6 A.M., at 12, and again at 6 P.M.

BRAMHAS OUT OF CONDITION (J. W. B.).—Give each of them a dessert spoonful of castor oil, afterwards give bread soaked in ale.

AYLESBURY DUCKS' EGGS (H. S.).—You need not be uneasy at the different colour of your eggs. It is common to all egg-laying birds. The Cochins lay some chocolate, some light brown speckled with white. Dorkings frequently lay brown eggs. Pheasants lay them of every shade, from sea green and light blue to a dark olive. Some attribute it to the condition or want of it in the bird, others to the state of the atmosphere. It is certain it is no sign of impurity of breed.

SKYLARK KEEPING (J. H., Glasgow).—In London they are generally fed on German paste, with about one-third the quantity of stale bun crumbled fine; in other parts of the country where this paste or composition is not known they are fed on whole grits and bruised hempseed mixed with bread crumbs, bruised oats, and poppy seed, cheese mites or mould, &c. They should have a turf every other day and plenty of clean gravel at the bottom of their cages, which should be cleaned out twice a week. A few mealworms, a few ants' eggs, and a few spiders now and then keep them in health and make them sing more cheerfully. They are naturally a strong and healthy bird, and may, if their cages are well sheltered at the top, back, and sides, be kept out of doors both day and night from May to August or beginning of September, when they will most probably go into moult. But they must be protected from draughts, winds, and rain, as they are apt to take cold, which brings on the husk. This is a very unpleasant complaint, as it frequently stops them when in full song. If their cages are properly boarded at the sides and back as well as at the top they will do best out of doors in the fine time of the year; it makes them stronger, and they will continue longer in song.

REMARKS.

- 6th.—Windy; fair day, overcast at times.
7th.—Very pleasant spring-like day.
8th.—Gusty wind during last night, colder and at times dull throughout the day, with intervals of bright sunshine. [the day.
9th.—Fair morning; foggy and dark at noon; cool and cloudy the rest of
10th.—Wet dull morning; fine bright sunny afternoon; solar halo at 5.30 P.M.; bright starlight night. [fine evening
11th.—Dull but fair morning; fine pleasant afternoon, though not sunny;
12th.—Damp morning; fine after 10 A.M., with bright sunshine; slightly foggy in evening.
Slightly cooler than the previous week, but very fine spring weather.—G. J. SIMONS.

COVENT GARDEN MARKET.—MARCH 13.

WE have no alteration to make from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 58.3°; and its night temperature 33.3°.

VEGETABLE CULTURE.

CHAP. XI.—ASPARAGUS.

 IN many parts of Britain as well as in several other European countries this much-esteemed vegetable grows wild. It is generally found near the sea, and is very partial to the rich sandy saline parts of the coast. Few gardens possess soil of that character, but Asparagus can be cultivated to great perfection in most garden soils. The only kind of soil to be strictly avoided for Asparagus-growing is a stiff clay, and soil about half clay does not suit it altogether, but is easily brought to the proper condition. Ground entirely free from clay requires only to be liberally manured before being ready for Asparagus. Soil, however, the least inclined to be clayey must have a good dressing of rich sandy compost added with the manure before it can be in a suitable state. Sandy mud is capital matter in which to grow Asparagus. In preparing our ground we first dig in a quantity of light manure; then refuse from the bottom of a pond, which consists chiefly of sand and decayed leaves, is added to the depth of 3 inches; this is also dug-in, and a final dressing of good cow dung is turned in some time after the sand. Digging the ground separately when each kind of manure is applied mixes the whole much better together than putting them all on at once. We apply all these ingredients to all kinds of soils, but in different proportions, according to the texture of the ground. Very light soil should have no sand added to it, but plenty of strong manure.

The soil may vary in depth from 1½ foot to 2½ or 3 feet. It should not be less than the first-mentioned depth. The best situation for Asparagus is one fully exposed to the sun but sheltered from strong winds, as the stems may be blown about injuriously when they are tall and slender in summer.

The best, or in fact the only way, of propagating Asparagus is from seed, which may be sown either in autumn or spring. I decidedly prefer the latter, and sow the seed from the middle to the end of March. There is only one way of sowing the seed, but it may be sown with different purposes in view. Sometimes it is sown in a bed, from which the plants are to be all lifted the second year and planted in the permanent beds. In other cases the seed is sown in the beds in which the plants have to come to maturity. We practise both of these plans at the same time, and we recommend others to do the same. After the ground has been thoroughly well prepared the seed beds are measured and marked off. Beds 4 feet wide hold four rows; the two outside rows being 6 inches from the alleys, which are 1½ foot wide. The other two rows come 1 foot apart. This is closer than is generally allowed for Asparagus, but I have not found it too close.

The old plan of raising the beds 8 or 10 inches above the alleys is quite unnecessary where the soil has been well prepared. The alleys need only be about 2 inches lower than the bed. On a dry day when the soil is not sticking to the feet the drills should be drawn about 1½ inch deep,

No. 994.—VOL. XXXIV., NEW SERIES.

and the seed be sown. The seed, if good, should not be sown thickly, and two or three seeds should not fall together. A little sifted soil and wood ashes or leaf soil should be spread over the seed before levelling down the soil drawn from the drills. The beds must then be raked over neatly, and nothing more need be done to them until the young plants can be seen in line. The Dutch hoe must then be run carefully between the rows, and this operation must be repeated frequently throughout the season, as an open surface and no weeds are the best inducements to growth that the young plants can have during their first season. By August the growth will be about 18 inches high, but the stems will not grow much after this, and it is important that the stems become well ripened in autumn. As a rule the beds of young seedlings will not require covering over with anything during the winter, but the withered stems should be left on all winter until about the beginning of March, when the beds may be very lightly hoed over and have the old stems removed.

During March many of the young stems will appear above the ground, and about the beginning of April when the young growths are from 2 to 3 inches high is the proper time to transplant the roots. When the roots are growing closely together our plan is to thin them out, leaving the remaining plants from a foot to 15 inches apart for the permanent crop. By this means the seed beds are left for cropping, and the plants which are lifted are planted in other beds for the same purpose. The beds for the roots which are lifted from the seed beds are prepared in the manner directed above. In planting, trenches of the width of a common garden spade are thrown out across the bed; they are 15 inches apart and 3 inches deep. The roots are spread flat out in the trenches, four being placed at equal distances apart in each opening, which form four rows the whole length of the bed. As the roots are set in their proper places they are covered over slightly with a mixture of leaf soil and sand, and the ordinary soil of the bed is then pressed gently but firmly against the young stems. This completes the transplanting, and it is an advantage when it can be done during mild dull weather.

After the surplus plants have been lifted from the seed bed the soil should be levelled around the plants left, and the Dutch hoe should afterwards be run between the rows to make the surface soil perfectly free and open. Should very dry weather follow the time of transplanting the beds are often much benefited by being watered, but this need not be done unless it is seen that the plants are stopped in their growth and look stunted. Throughout the season both the original seed bed and the spring-planted beds must be hoed frequently and kept free from weeds, and by autumn the plants will have made strong stems. As soon as these are withered they should be cut down close to the surface of the ground, and the best manure obtainable should be spread on the beds to the depth of 2 inches; the plants will live without this covering, but it is a great help to them. About the beginning of March this covering should be taken off and the beds be carefully hoed over, not so deep as to cut any of the young shoots which may be starting. The plants will now make their third year's

No. 1003.—VOL. LIX., OLD SERIES.

growth, and if they have done well the shoots will push up very strongly; but the heads will be all the better the following year if none of them are cut, as it is liable to cripple the roots when the best of the shoots are cut too soon. After the third season a little of the shortest of the manure may be left on the beds in the spring and be forked lightly into the surface of the soil, or those who are afraid of injuring the roots may leave it on the surface without forking it in. The fourth season after sowing great quantities of fine shoots will be produced for cutting, and the beds will be getting into prime condition. In cutting, none of the shoots should be left to grow until cutting is wholly discontinued, and to give the plants a fair chance no heads should be cut after the middle of June.

Asparagus beds carefully made and well attended to will bear heavily until they are ten and twelve years old, but after they reach this age it is often more profitable to do away with them and have new beds in bearing order ready to replace them. Seaweed is better than manure for covering the beds, and where it cannot be had salt should be applied liberally when the manure is taken off the beds in the spring. The poorer the soil is the more salt should be given. When beds are becoming old and exhausted two or three good waterings with strong liquid manure during the dry weather in summer invigorate them very much.

Forced Asparagus is always much valued, and various modes are adopted for providing a supply before it is ready in the open air. In exceptional instances provision is made for forcing the roots when the beds are made. The ground is dug out 3 feet wide and the same in depth where the alleys have to be. A pigeon-holed brick wall is built up on each side to the ground level, and beds of the ordinary width are made between these walls. The plants are treated as in other beds, but when it is desired to force a bed in spring the vacancy between the two brick walls is filled up with hot manure, which heats the soil through the pigeon-holes. At the same time triangular-shaped covers are made either of wood or glass (glass is the best) to fit on to the brick walls and protect the heads when they come up early. This plan saves all lifting of the roots, but it is rather an expensive one. We adopt a less elaborate plan, and we cut Asparagus from the middle of November until the middle of June. We force it in a Cucumber house, but an ordinary hotbed and frame answer equally well. Where there is a bed with bottom heat in a Melon or Cucumber house a thin layer of soil should be spread over the bottom of the bed, and on this the Asparagus roots should be placed close together and be covered with 2 inches of soil. With a bottom and top heat of 60° growth soon begins. To secure full flavour the shoots must be grown fully exposed to the light, and air must be admitted when it can be done with safety. In forcing in a hotbed the mode of planting and the heat required are the same as when fire-heated pits are employed. After the roots have been forced they are not worth planting again and may be thrown away. The roots force best and are most productive between four and eight years old. The stems (heads) should not be cut from the roots the season previous to forcing, as the plants come to maturity sooner and are more productive when treated in this way.

Connover's Colossal grows larger than Giant or Battersea, but they are both excellent varieties for general cultivation. —A KITCHEN GARDENER.

PRUNING ROSES.

"WYLD SAVAGE'S" remarks under the above heading (page 162) are very seasonable and doubtless very acceptable to the exhibiting section of Rose-growers, but hardly applicable to the section he denominates "the cultivators of the garden Rose." The latter are undoubtedly in a great majority in point of numbers, but among the former are to be found the ablest and most enthusiastic growers and real lovers of the Rose—men well able to hold their own in argument or otherwise. Gardeners can and do admire the beautiful in all things, including Roses, but have but little time to devote to them, consequently have of necessity to take a practical view when selecting, growing, &c.

Roses on the Briar are still the most popular, and are certainly the least trouble to the cultivator, very little attention being required to keep them in good working order for years. Practical gardeners require no advice upon pruning them, but there are many amateurs and jobbing gardeners who apparently know but little about pruning, and to these my remarks I trust will prove of service. Roses, if required shapely and to

last a number of years, must be well and properly pruned. Too often the operator's sole aim apparently is to leave a neat compact head, with the growth both weak and strong of much the same length. What is the result? The strong overpruned growth produces still stronger and perhaps flowerless growth, the weak becomes still weaker, and in time an unsightly head with a minimum of bloom results.

Gardeners as a rule do not study the names when pruning; what they take notice of is the general appearance of the previous season's growth, and prune accordingly. Weak-growing plants are closely pruned to induce more vigorous growth, and strong shoots are cut in proportion to the growth made. When commencing on a good healthy head all weak growth is cut clean out, and where necessary to keep the plant within bounds the outer shoots with the old wood are cut back to the selected shoots. A limited number of the latter are retained according to the age and size of the plant, and these are shortened if extra strong to about four or five eyes, if moderately so (about the thickness of a lead pencil) to about three eyes. The centre in young plants is generally kept pretty clear of growth. Overcrowding the shoots should always be avoided; and on the other hand, if too hard pruned, strong growth and but little bloom is the result. This will be evident to the operator when next he prunes, and ought to be accepted as a hint to be more or less free with his knife.

Of course the Tea Roses require a different method of pruning. If vigorous, the shoots only require a slight shortening and the old and weak growth removed; if weak, they may be pruned similar to the Hybrid Perpetuals. Good heads of bloom may be thus obtained, but the supply is not so continuous. Roses are often scarce during the late autumn and early winter months. To obviate this I have found it an excellent plan at pruning time to cut hard back a vigorous shoot of the Gloire de Dijon Rose; strong growths follow, which mature early, and if slightly turned will yield a good supply of bloom till cut down by frost. These shoots sometimes flower at the point; cut this, and more flowers soon follow. Céline Forestier, if pruned similarly to the Hybrid Perpetuals, produces fine bunches of bloom; in fact I find this one of the most useful varieties. We have also had a fine lot of bloom from standards of Maréchal Niel. They are planted on a southern aspect; the heads are trained and are now showing an abundance of buds, which, however, will have to be protected or will be worthless. La France is a great favourite and is invaluable when grown in pots, especially as standards. Roses if pruned as above described will give a good supply of serviceable bloom, although they may not be fit for exhibition. It is very advisable to always cut close to an eye and thus avoid having to cut out any dead wood, the result of slovenly pruning.—W. IGGULDEN.

PROTECTING CHOICE STANDARD PEARS OR APPLES.

THE trees are capable of being grown in many shapes and under many circumstances: hence we have espaliers, standards, trees trained on walls and grown in pots, inside or outside with moderate heat, under peculiar circumstances, or better without any. Climate and seasonal variations affect the Pear and choice kinds of Apples during this critical season when flowering and impregnation are so much affected by the weather. Successful impregnation is of vital consequence in insuring the future crop. The mildness of the season in this locality has caused the flowering period to arrive nearly a month earlier than usual. But precaution is all the more necessary on that account.

I would mention for the information of your readers a convenient, cheap, and tolerably effective sort of protection adopted by Mr. John Crehan, Minella Gardens, near this town, which reduces the danger to open-air pyramids to a minimum.

Four firm stakes are driven into the ground equidistant, and so as not to interfere with the branches or flowers. A piece of strong canvas or calico is then tacked on one end reaching down low enough so as not to prevent a free circulation of air upwards, and high enough so as not to prevent the action of the sun downwards, almost horizontal with the top of the tree. This piece is then carried around the others and joined at the first, forming an effectual barrier against March blasts, and especially against those whirling winds that frequently gather force inside walled gardens, and have been known to play havoc among tender buds and young flowers by violently striking and rubbing branches together irrespective

of the otherwise harsh, dry, withering influence of the winds. This simple arrangement very effectually diminishes their influence, and nowise interferes with the action of the sun or the beneficial influence of a genial April shower, while it combines the characteristics of utility, cheapness, and convenience. Those who appreciate a choice fruit tree will not grudge the trouble of an operation that may conduce materially to success.—W. J. M., *Clonmel*.

PLANTING GERANIUMS IN TURVES.

THIS is an important part of my spring work in preparing a considerable number of bedding plants; and having very few pots at my disposal and no "shelves near the glass," I succeed to the satisfaction of a rather "crusty" old gentleman and four critical young ladies by the aid of a few turves dug from the wayside, and a few frames and home-made pits. I act on the advice of the late Mr. R. Fish, whose instructions I copied, and I copy them again for the benefit of many who are now "in a fix" for want of pots and house room for the accommodation of Geraniums, &c., which are spoiling each other by being crowded in cutting pots and boxes. The following is what I term Mr. Fish's recipe, and a valuable one it is, as I have proved by ten years of experience. "We cannot," says Mr. Fish, "find anything better as a substitute for pots than pieces of fibry turf. Thus, suppose from the side of a road or an old pasture you can take some turf 2½ inches thick and in breadths of 1 foot. We place that turf where it will be gently dried a little and warmed, and we prepare a little warmed, light, sandy soil, consisting of loam, sand, and very sweet old leaf mould. Then for stoutish plants of rooted cuttings with a sharp knife we cut our turves longitudinally and transversely into pieces of 4 inches square, for less plants 3 inches square, and so on; and a clever handy lad will scoop out a round centre piece from each of these square turves nearly as quickly as he would crock a pot, just leaving a bit all round the side and not going quite through to the grass of the turf. A little of the mellow heated soil is placed in the hole, the roots put in over it, a little more soil put over the roots and firmed as in a pot, then carried in sieves to their position, and watered with water from which the chill has been taken off. Now as to the position. For quick work—that is, making small plants large, and to have the turf pots bristling with roots all over, the best plan is to set these turf pots on a little leaf soil over a hotbed, however slight, as that will increase the rapidity of the rooting and growing; but in that case the turves must be lifted as soon as the roots come through them, and transferred to light soil in a cold pit, &c. If left long the roots would run through the bed, and the plants could not be safely turned. If taken in time to the earth pit and the trench the roots will progress more slowly, and when planting time comes they will hang like a wig round their centres of turf. When planted turf and all together they will run away into the well-aired soil, and thrive better than if they had come out of a pot with the ball unbroken. This is a good plan for all plants with straggling roots that will not lift well out of an earth bed, as *Manglesii* Geraniums, *Heliotropes*, &c."

By carrying out the above advice I annually produce far finer plants than the few I grow in pots, and I feel certain that whoever adopts the practice will find it both effectual and economical. I not only grow Geraniums, such as the scarlet-flowered and variegated-leaved varieties, in the manner described, but also *Verbenas*, *Ageratums*, *Salvias*; indeed all plants required for bedding-out in May.—A GROOM AND GARDENER.

BLASTING TREE STUMPS.

"PADDLE" asks how to do this. They can, of course, be blown up with powder, but by far the best way is to obtain some tonite cartridges from Mr. Dineen, the patentee, Queen Street, Leeds. He came here a short time ago to give a sample of the power and safety of the explosive, and to instruct my men to use it, and certainly wonderful were the effects. We bored holes slanting into roots and placed in each of them a cartridge with cap and fuse, and in a few seconds the root was blown to pieces, some requiring a second application.

Tonite is perfectly safe till the cap is applied. You may set it on fire in your hand, and it burns away like a bit of sealing-wax. The only danger is in fastening the cap to the cartridge and stemming it when ready in the hole; still there is no danger if the directions are attended to. It has the force of

dynamite without the danger, as it can do no harm till confined. Proper directions are sent with the cartridges, which are not expensive. The effects are still more marked applied to stone. Anyone interested in the subject will find a full account some months back in "The Journal of Forestry."—J. P., of *York*.

IS IT NECESSARY OR BETTER TO REMOVE RASPBERRIES OCCASIONALLY?

IN an article on the Raspberry I remarked in regard to the planting of the canes—"Clear the ground, manure it, and be sure no Raspberries have ever been planted there before, because in time they 'grow sick of the same soil.'" I have noticed what "D., *Deal*," and others have said controverting my statement, but strengthening myself by the opinion of gardeners near me I remain of the same opinion still.

I grant it may be possible for Raspberries under exceptionally favourable circumstances of soil and situation to do fairly well in the same place, but I believe they would have done better had they been removed every few years. Such is my experience. I have occupied the same house for twenty-two years, and have just recently removed my Raspberry canes for the third time, I rather think the fourth time. The result of the removal in each case hitherto has after the first year been a great increase of the crop. Then after a few seasons have rolled on there has always been a diminution of the crop. Then, further, the canes grow sick of the soil, which they show by burrowing under the soil and trying to escape. They have after a few years a strong tendency to run to a distance, mole like, by means of underground stems. Here we have Nature not only, as I take it, exerting her powers of extension, but seeking a new soil for bettering herself. I went into the question yesterday in respect to a large garden near me, where one of the under gardeners has worked continuously for forty years, and he says just the same, pointing to canes now almost useless which in former years were very productive. This, too, is borne out by another, and in this instance head gardener. But I would further say, Is not everything the better for occasional removing? Look at the state of the soil under any plant which has remained in the same place for years. "Sour," my old man calls it; dry, lumpy, worn-out it looks. But the Raspberry burrows away—sensible plant—in order to get into new ground. I state this as a general rule to follow.

"A MIDLAND COUNTIES FRUIT-GROWER" is very guarded in his opinion, commencing his remarks with "provided." Now, when a man begins with a "provided" he is cautious and by no means sure. He guards himself and his opinion, and very rightly too. Still, in spite of his lawyer-like and Scotch-like (is he not a canny Scot? I think he must be), I remain of the same opinion as before. Then my careful midland counties friend states that it "is prudent in making a new plantation to select ground that had been occupied by some other crop." So do I. In his recommendation for the general growing of Raspberries I of course heartily concur, as I have recommended it in my article. The few words by R. N. G. Baker and by another writer in *Notes and Gleanings* do not call for remark, as they do not controvert my opinion that Raspberries will do better if removed periodically. It is not sufficient that under exceptional circumstances they have done well remaining where they were. We have not had a little difference of opinion on paper for some time. We have been wondrously unanimous. Differences sift matters and the truth remains; the chaff and dust are driven off. I do not like personal controversy; people get red in the face, their eyes grow unduly bright; then men will get up from their chairs, stand before the fire, as if that would make them cooler. Then comes a long pause in conversation, and other people are sedulously talked with, and at the end of the party there is a ceremoniously-said "Good evening," the good being prolonged "Go-o-o-o evening." But on paper it is all different; there is that cool cucumber-like being called an Editor, with his pen in hand to strike out when needed, and to stop the fight if required. Oh! cool Editors, quite free from the fight—looking on, amazed doubtless, but still cool and cool always. What blessed benefactors ye are!—WILTSHIRE RECTOR.

ANTS PRESERVING APHIDES.

I RESPECTFULLY beg to differ from you in the opinion that ants are enemies to aphides. I have lived at three different places, where they were considered regular pests and destroyed them

accordingly. I have closely observed them, and have never seen any good resulting from their labours—quite the reverse; their sole aim is to preserve the aphides and other insect pests from view as much as possible. This, however, is from purely selfish motives, in order that they may enjoy the excrement. They completely cover mealy bug and scale with particles of soil, and this on growth some distance from the soil. Mealy bugs when so covered soon attain a great size. I have seen the Ladybird (*Coccinella*) thoroughly clear a plant badly infested with mealy bug. — W. IGGULDEN, *The Gardens, Orsett Hall, Romford*.

CULTIVATION OF SALADS.

CUCUMBERS.—In offering a few remarks on the cultivation of the Cucumber I will confine myself to those grown in frames. Cucumbers can be well grown in frames heated with a flue; the flue should run through the centre lengthways. Thick planks may form the foundation of the bed, and should be laid 15 inches above the flue. About 1 foot in depth of soil will be sufficient, but as the roots show on the surface more soil must be added—about an inch will do at a time. This must always be kept very moist, for the one thing that will bring disappointment in Cucumber-growing is keeping a dry atmosphere. Cucumber plants to last some length of time must be well pinched back, and when each shoot has made two or three joints it must be stopped. When the plants commence bearing a surface dressing of rich loose soil once a fortnight will be required, and the foliage must be kept thin, healthy, and clean. When sufficient manure can be obtained to make a good hotbed it is far preferable to fire heat. The quantity that will be required should be thrown up in a heap, turned over, and be well mixed together with one-half of leaves. The heat will not then be so intense and will last much longer than if the bed were made with manure alone. The seeds may be sown or the plants planted when the heat is down to 70°. The heat should not fall below 60° in the night, rising to 75° in the day with sun heat before air need be given. When the sun has great power it will be necessary to damp inside the frames twice every day, the first time about 9 A.M., when air should be given, and again early in the afternoon when the frames are closed.

LETTUCES.—The first sowing of approved Cos and Cabbage varieties should be made on a gentle hotbed early in March. The plants from this sowing will succeed those sown in the autumn. Sow also under a handlight on a warm border about the middle of the present month. Successional sowings should be made every three weeks during the summer in a damp situation and on good rich soil.

ENDIVE.—This may be sown the same as the Lettuces, but if so the plants must be planted on a north border, and if dry weather follows they must be well watered to prevent them running to seed. The main sowing should be made at the beginning of July, planting-out in rich soil in drills 3 inches deep. When the plants are large enough the ground should be run through with the Dutch hoe, which will fill the drills up. This will blanch the plants to a certain extent. They can then be tied-up the same as Lettuces, or have a flower pot inverted over them when a supply is required through the winter. They should be planted in cold frames to succeed those planted in the open ground. The Batavian is a very hardy variety, and is valuable for late use. It will endure severe frosts, but if a covering can be found so much the better to keep off the rain and snow during the winter.

RADISH.—The first sowing in the open ground should be made early in March, sowing again every fortnight during the summer months, the last sowing to be made at the beginning of September.

CRESS (Plain).—This can be sown in the open air the greater part of the year, and in heat during the winter as wanted. *American Cress.*—This is very useful where dressed salads are required, and may be sown as recommended for Radishes.

CHICORY.—The seed should be sown in drills in March 15 inches apart, and the plants be thinned-out to about 12 inches. The roots should be taken up in November and stored away in a dry cool place. The roots can be started into growth by various means in heat through the winter, but must be kept in darkness, so as to blanch the leaves as they grow; they can then be picked as required.

BEEF.—The seed may be sown about the middle of April, and the plants be thinned-out to the same distance as recommended for Chicory.

CELERY.—The first sowing is usually made in heat about the middle of February and the plants grown under glass. They should be first pricked-out in boxes or pans, and subsequently be potted-off in 60-sized pots, and after being gradually hardened-off be planted in a rather deep trench as soon as possible. If well watered and cultivated the Celery will be ready for use early in August. The sowing for the main crop can be made on a gentle hotbed about the end of March or beginning of April. When the plants are large enough they should be pricked-out 3 inches apart on beds. Before the bed is made place some slates or boards to form the bottom, then cover them with an inch of half-decayed leaves or rather long manure, then add on the top 2 inches of fine rich soil. Water copiously, and the plants will grow freely and can be removed with plenty of good roots. Where Celery is required in March and April it should be planted-out in August, and not be earthed-up, or only very slightly, till sharp weather occurs in late autumn, choosing a very dry day for the operation.

ONIONS.—These are very useful for salads, and can be had young by sowing a little seed once a month from March till September.—W. ETHERINGTON, *Swanscombe Manor*.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THE charms of spring lead us first to the herbaceous ground, and there we find many choice beauties both new and old. *Tulipa stellata* is rather of botanical interest than horticultural value. It is remarkably narrow and slender in all its parts; the leaves are almost grassy, and the white flowers answer well to the specific name. It comes next to *T. Clusiana*, of which Regel made it a variety, but Mr. Baker in his Monograph prefers holding it a distinct species. It is a native of the Western Himalayas, and was contributed by Mr. William Bull. A figure will appear in the "Botanical Magazine."

Chionodoxa Forbesii and *C. Tuciæ* are two species of a genus not, until recently, in English gardens. The latter in particular is very bright and delicate. The flowers of it are about an inch across, something like *Puschkinia*, to which this genus is nearly allied, but wanting the corona. The colour is very bright blue on the outside, paling to pure white in the centre. It comes from Asia Minor.

Iris reticulata var. *Krelagei* we notice to be among the species, of which there is a fine clump. It is not nearly so bright in colour as the species, but is very good. The flowers are plum-coloured.

Among the *Narcissi* is *N. juncifolius* var. *rupicola*, a very rare and choice form, one distinguishing particular of which is the notched corona. A form of *Snowdrop* we observe is curious, indeed is more curious than beautiful. The ovary is yellow, and within pale yellow is substituted for the lively green which constitutes some part of the attractiveness of the common wild form.

Jatropha-podagrica, a species with dwarf gouty stems, is happy in its curiosity from the possession of very showy scarlet flowers. No other is more ornamental or more curious in its habit. It is now flowering in the stove, and is native of Santa Martha.

Griffinia ornata is flowering in the Begonia house. It is a new member of this interesting and often very beautiful genus, and was introduced by Mr. Bull from Brazil. It is one of the largest species. The bulb has something the form of that of *Crinum ornatum*, and the foliage, too, has a *Crinum*-like strength and appearance, but is much handsomer. The scape is about 18 inches high, and in this instance bears an umbel of a dozen flowers, which are nearly white, having a tinge of lilac. This genus is not at all well known in gardens, although it is one of the choicest for stove culture. Several species are small-growing and suited to choice selections. The true *Eucharis candida* is in flower, and truly there are few plants more floriferous.

DUKE OF BUCCLEUCH GRAPE.

"A MARKET GARDENER, N.B.," on page 181, has made a statement in regard to the above Grape that has no foundation in fact. He says it was regularly syringed here up to within a short period of its being ripe. The only times water is so applied to any Vines here is once after the Grapes are set, with a view to clear the bunches of the loose pollen and stamens, and to facilitate by that means the process of thinning; and in the case of a leaf or two at any hot corner showing red spider, but not to an extent making it worth while to sulphur the pipes. The leaves are then washed with the syringe, but

the fruit is carefully avoided. All my men past and present can testify to what I here state as being perfectly accurate. Permit me to say that I know of no market gardener visiting this place annually.—W. THOMSON.

ROYAL HORTICULTURAL SOCIETY.

MARCH 19TH.

For the first time during the season Hyacinths and Tulips were exhibited, and imparted quite a cheerful appearance as associated with the Palms and other greenery of the conservatory. The Hyacinths, which were contributed by Messrs. Veitch, Cutbush, Osborn, and Carter & Co., were not as a rule nearly so good as we have seen staged during past years; still we observed many excellent spikes. The conservatory was quite filled, and the exhibition was an attractive one.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Iggulden, gardener to R. B. Wingfield Baker, Esq., Orsett Hall, Romford, sent a dish of Tomatoes said to be a cross between Hathaway's Excelsior and Sims' Mammoth, but considered by the Committee as Hathaway's Excelsior. It was awarded a cultural commendation. Mr. Iggulden also sent a seedling Apple, but it was not considered better than other varieties already in cultivation. Mr. Elliott, seedsman, Braywick, Maidenhead, sent specimens of the green variety of the true Buda Kale. He also exhibited a kind of shading for glass structures. The prospectus says—"It produces a delightfully pleasing shade that can only be compared to a light green or grey cloud over the face of the sun, and Ferns and other delicate plants and flowers are seen to better advantage and appear more pleasing to the eye than when seen under any other condition. Five years' experience has proved that it is very beneficial to vegetable growth, for, while it breaks up the direct fierce rays of the sun and produces a desirable amount of shade, it does not deprive the plants of a large amount of light so necessary to their healthy development."

FLORAL COMMITTEE.—Dr. Denny in the chair. We will glance at the groups in their order of arrangement. Near the entrance of the conservatory at the east end was arranged a collection of plants from the Society's garden at Chiswick, including Eucharises, very good varieties of *Imantophyllum*, small well-flowered plants of *Conoclinium lanthimum* (figured on page 206), and standard plants or miniature trees of *Wistaria sinensis*, which were very attractive. The group was edged with small plants of *Isolepis gracilis*. A small plant of the singular *Dendrobium linguaeforme* from Chiswick was awarded a botanical commendation.

The next group was arranged by Mr. Aldous, florist, Gloucester Road, South Kensington. It consisted of early-flowering Pelargoniums, Azaleas, Cinerarias, Heaths, Lilies, Palms, Ferns, and Mignonette. Messrs. Cutbush & Son contributed an excellent and well-arranged collection, comprising large round baskets of Epacris, Ghent and Indian Azaleas, very fine pans of Lilies, and good Hyacinths. *Ericas colorans* and *gracilis vernalis* were attractive in this collection. Messrs. Cutbush & Son had a first-class certificate for Hyacinth Grand Master. The spike is tall, bells reflexed and thinly arranged; colour very pale blue striped with dark blue. A fine spike of the same variety was in Messrs. Veitch's collection. Messrs. James Carter & Co. had the next group, which was composed wholly of Hyacinths. Many of the spikes had not quite arrived at their best, but the colours were well mixed and a cheerful effect was produced.

We now arrive at the centre of the building, and find a very fine collection of Hyacinths and Tulips from Messrs. Veitch and Sons. Although we have said that Hyacinths are not so good as usual this year, many undoubtedly good spikes were in this collection. The Tulips were excellent, as also were the Narcissuses. Messrs. Veitch also exhibited a small group of Hippeastrums; *spectabilis*, white flaked with scarlet; and *cruenta*, crimson scarlet, being very fine; also an effective basket of flowering sprays of hardy shrubs. These included *Daphne mezereum* and *mezereum alba*, *Azara microphylla*, *Viburnum Tinus rugosum*, *Grevillea rosmarinifolia*, and hardy Heaths. First-class certificates were awarded to the firm for the fine deciduous *Magnolia Halleana* from Japan. The flowers are white, and the narrow strap-like petals reflex gracefully. It is very attractive and delicately perfumed. It is as pure and sweet as the white Water Lily, and is a valuable addition to early hardy-flowering shrubs; also to the curious Orchid *Bollea Patini*, the fleshy petals and sepals rosy violet tipped with purplish magenta; also for Hyacinth King of Blacks, a variety with a fine spike and large well-formed reflexed bells, black faintly tinted with violet; an excellent variety. A new Hyacinth, Queen of the Blues, was also much admired for its symmetrical spike, fine flat bells, and bright colour.

In contrast with Messrs. Veitch's flowering group was a collection of plants arranged by Mr. Wills. The ground was composed of Ferns and Lycopods, amongst which were thinly interspersed such Orchids as *Phalaenopsis* and *Odontoglossums*; *Anthuriums*, *Cyclamens*, and *Callas* were also included, and a few choice Palms. It was very fresh and pleasing. The adjoining group was from Mr. B. S. Williams, and was formed chiefly of a brilliant bank of

Hippeastrums, the varieties varying in colour from pure white to rich vermilion-scarlet. Mr. Williams also staged a very fine plant of *Imantophyllum miniatum* with about twenty flower heads. *Oreopanax dactylifera* in this collection was distinct by its massive palmate foliage. Messrs. Osborn & Sons, Fulham, staged an extensive and excellent group of Palms and other ornamental-foliaged plants. The striking flower in this collection was *Imantophyllum miniatum major*, a variety with large highly coloured flowers and broad dark foliage. Messrs. Osborn also exhibited three Abutilons—Lady of the Lake, rose; Orange Perfection, and Aurea globosa. They also arranged a collection of Hyacinths and Tulips.

A first-class certificate was awarded to Mr. Mill, gardener to Lord Rendlesham, Rendlesham Hall, Woodbridge, for *Odontoglossum pardinum*, a valuable Orchid for decorative purposes, the plant being evidently of free growth; the spike is strong, gracefully arched, 2 feet long, and with seven or eight branchlets of bright orange-yellow flowers spotted with reddish brown. The waved petals impart a distinct appearance to the plant. Mr. Hall also exhibited cut blooms of *Cattleya Skinneri*, remarkably rich in colour, for which a vote of thanks was awarded.

Mr. Iggulden, gardener to R. B. Wingfield Baker, Esq., Orsett Hall, Romford, exhibited very fine cut sprays of *Sparmannia africana* (figured on page 91), and was awarded a vote of thanks. Messrs. John Laing & Co., Stanstead Park Nursery, staged three *Caladiums*, one of which, *La Perle du Bresil*, was singularly chaste, its surface resembling silver tissue paper traversed with distinct chocolate veins. Mr. Cannell exhibited cut blooms of his white, scarlet, and striped sports of *Geranium Vesuvius*; also extremely floriferous plants of the salmon variety, which cannot fail being valuable for bedding purposes. The Committee desired to see it bedded out before adjudicating on it. It is distinct in colour and very promising. Mr. G. F. Wilson had a vote of thanks for *Erythronium Dens-canis grandiflorum*. The flower is straw-coloured, and the foliage marbled—very attractive. Messrs. Rolliason and Sons exhibited the dwarf double Japanese Azalea *Rolliasonii*. The flowers are rosy scarlet, imbricated, and well formed—very distinct. Messrs. Garraway & Co., Clifton, Bristol, exhibited plants of Garraway's White Mignonette, the spikes being very delicate and sweet. Mr. Parker staged a collection of *Megasias* and a fine plant of *Erythronium Dens-canis purpureum*, which was highly attractive. Mr. Lee, Clevedon, Somerset, exhibited some bunches of *Violet Odoratissima*, the flowers being large, round, blue, and very sweet.

Mr. R. Dean staged a collection of hardy spring flowers, including several small alpine species of *Primula*, *P. denticulata* being very fine. *P. purpurea* appears to be an improved variety of this useful species. *P. nivalis* was also highly attractive. The collection also included several *Polyanthuses* and *Primroses*. Octoroon and Magenta among the latter are promising varieties for garden decoration. Messrs. Barr & Sugden staged several cut flowers of *Narcissus*, to one of which—*N. incomparabilis aureo-tinctus* Leedai—a first-class certificate was awarded. The perianth segments are pale yellow, and the corona orange-yellow. The pretty *Iris persica* and one or two others were also exhibited by Mr. Barr. Mr. Cauldwell, Wallingford, staged cut blooms of *Polyanthus* in good decorative varieties. Mr. H. Parr, The Gardens, Harrow Weald Park, Stanmore, was awarded a vote of thanks for *Begonia glaucifolia* grown as a basket plant. The flowers are pale in colour, but the habit of the plant is distinctly pendant, which renders it suitable for special decorative purposes. An attractive bloom of *Tulipa præcox* was exhibited by H. J. Elwes, Esq., Preston House, Cirencester.

Besides the marks of recognition above recorded the following medals were recommended. A small gold Banksian medal to Messrs. Osborn; a silver-gilt Flora to Messrs. Veitch for Hyacinths and Tulips; a silver Flora to Mr. B. S. Williams for Hippeastrums; a silver Banksian to Mr. Wills; a silver Banksian to Mr. Aldous; a silver Flora to Messrs. Cutbush; and a bronze Flora to Messrs. Carter.

At the afternoon meeting Col. Trevor Clarke in the chair, Mr. Samuel Jennings, the Assistant Secretary, read an interesting paper on the Epacris, illustrated by flowering sprays of several species and varieties. The lecture was attended by a considerable number of visitors.

Twenty-eight new Fellows were elected during the afternoon.

NOTES AND GLEANINGS.

At a general meeting of the Royal Horticultural Society held yesterday, Col. R. Trevor Clarke, V.P., in the chair, the following candidates were elected FELLOWS—viz., Mrs. Bourne, Mrs. Brooker, Rev. T. Carroll, M.A., Wm. Caudwell, Mrs. Chalmers, Miss Cole, Alex. Courthorpe, Mrs. J. H. Dobree, Walter Drummond, S. Elliott, jun., Master Foster, Col. R. Temple Godman, Matthew Hedley, Mrs. Staveley Hill, Mrs. Seton Karr, Col. Sir Henry Atwell Lake, K.C.B., James Levesley, Capt. R. C. Mayne, R.N., C.B., W. J. Nutting, jun., Denis M. O'Connor, M.P., W. W. Rust, Mrs. Streatfield, G. M.

Tagore, John Tennant, H. Payne Townshend, Dr. John A. Tulk, R. A. Valpy, J. Sidney White, &c. The following were admitted guinea members—viz., George T. Whish, Mrs. George T. Whish, Miss Reeve, and A. McLean. The Nottingham Floral and Horticultural Society was admitted into union.

— AT the monthly meeting of the UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY held at the Caledonian Hotel, Robert Street, Adelphi, on the evening of March 11th, the Chairman of the meeting on behalf of the Committee and members presented Mr. J. F. McElroy with a watch and chain in recognition of his services as Honorary Secretary of the Society.

— As a herald of the coming campaign of the war of the Roses the schedule of the ALEXANDRA PALACE ROSE SHOW, to be held on June 22nd, is issued. The Show is limited to one day, and that a Saturday. No other day, we may presume, could be relied on by the Managers to ensure a sufficiently large attendance of visitors. To many ardent rosarians, including some exhibitors, Saturday is a proverbially inconvenient day; but such will at least agree that the Show had better begin and end on that day than open on Friday and continue over two days. The Saturday public will, too, have the privilege of enjoying an exhibition worthy of their patronage, which a Rose Show certainly is not when thirty-six hours old. The Managers of the Alexandra Palace have hitherto been fortunate in their fixtures, and admirable displays have resulted; but this year the authorities have fixed the date of the Show eight days earlier than last year. The prizes are liberal, and are arranged in the usual order, five classes being devoted to nurserymen, six to amateurs, and nine are open classes. Four prizes are offered in all the principal classes.

— ON the morning of the 14th inst. at Longleat, Warminster, was registered 11°, on the 15th 8°, and on the 17th 11½° of FROST. Peaches and Pears are getting too forward to allow one to feel quite comfortable about them under such low temperatures; but still the fruit bloom is quite a fortnight later than it was last year, and consequently there is a greater chance of saving as much of it as the cold wet summer allowed to perfect.

— WE have received pips of gold-laced SEEDLING POLYANTHUSES from Mr. R. Kirke Penson. The plants have been out in the open ground all winter, and the flowers are consequently small. They, however, possess the desirable properties of being round and flat, with thrum eyes, a smooth yellow centre, very rich maroon body colours, and bright and clearly defined lacing. The only fault we can perceive in the flowers is that the segments are rather too much pointed. The varieties are worthy of good cultivation, and if the plants possess healthy habits and have good foliage and flower stems they will be well worthy of a place on the exhibition table where such flowers are shown. We have not seen more promising seedlings for a long time.

— AMONGST spring-flowering shrubs, writes "A KITCHEN GARDENER," *BERBERIS DARWINII* has few or no equals. It has been in bloom in the pleasure grounds since the beginning of March. Every shoot—many of them 3 feet long—is thickly set along the under side with clusters of buds and orange-yellow flowers, which are not only exceedingly beautiful on the bush but very valuable in a cut state for mixing with other flowers. The plants bloom when quite small, and they will grow in nearly any kind of soil or situation.

— AS an instance of making a FLOWER BED ATTRACTIVE IN EARLY SPRING with the aid of a few simple materials one of the beds at Munster House, Fulham, is worthy of mention. It is a round bed, and only two kinds of plants are employed—namely, Golden Feather and red and white Daisies. Small plants of Golden Feather about an inch in diameter raised from seed sown in the summer are planted round the bed and also across it in six equidistant lines, which form bright margins to as many triangular-shaped spaces. These wedge-shaped spaces are alternately planted closely with red and white Daisies, and the effect produced is very cheerful both when viewed from a distance and examined closely. When plants so hardy and so easily raised are capable of producing such a pleasing display in March there can be little excuse for bare beds. The bed, too, will improve in beauty until the middle of May—just in time for its being prepared for summer decoration.

— THE flowering ALMOND TREES (*Amygdalis communis*) are now very beautiful in the gardens around London, and impart quite a cheerful appearance to shrubberies and villa

gardens. The trees are flowering very profusely in spite of the keen winds and occasional frosts which have lately prevailed. This is one of the earliest of flowering trees, and is sufficiently hardy to thrive satisfactorily over a large extent of the country.

— It is a long time since so much MARCH DUST has been seen as during the present month. Valuable as it is, or the weather promoting it, on the farms and in the gardens of the country, the dust is a nuisance in London, and street-watering both in the City and suburbs has been necessary since the beginning of the month. The soil in gardens and nurseries has been in splendid condition for working. There has been a considerable fall in the temperature during the past week, which has been very welcome for retarding the expanding blossom of fruit trees.

— THE question of which is the EARLIEST and QUICKEST-GROWING CUCUMBER is a matter of considerable importance to many cultivators. We have lately inspected the early crop of an excellent cultivator—Mr. Rapley, gardener to R. Hudson, Esq., Clapham Common, and Osmaston Manor is fully three weeks earlier than Tender-and-True, Telegraph, and other popular varieties. The same results were produced last year, for the cultivator obtained a cultural commendation for Osmaston Manor before the other varieties named had set any fruit. This year the appearance of Osmaston Manor is very striking by the fine crop of fruit now hanging, some of the Cucumbers being 2 feet in length, while Tender-and-True is only just setting its first two fruit. The plants are all of precisely the same age, and have grown alike freely. Where Cucumbers are desired as quickly as possible, as is not unfrequently the case, Mr. Rapley's two years' experience is worthy of being recorded for the guidance of others.

— HAARLEM, the great Tulip town, exhibits at the Paris Exposition a bed of 40,000 BULBS.

— THE long glass range in the nurseries of MESSRS. OSBORN & SONS at Fulham is now very gay with American and Ghent Azaleas, which are very valuable for early decoration and for affording cut flowers. The plants are hardy, of easy culture, and represent a great variety of colours associated with fresh green foliage. The Chinese Guelder Rose, *Viburnum plicatum*, is also extremely attractive, the flowers being large and very pure. It is a forcing shrub of the first order of merit. *Conoclinium ilanthinum* is also flowering effectively, as also is the scarlet *Burchellia capensis*, and several varieties of *Epacris*. These, with *Hyacinths*, *Tulips*, and *Narcissuses*, which are well grown in this nursery, render the houses bright and cheerful. Ferns and Palms afford sufficient relief, a fine stock of *Adiantum farleyense* being grown in pure loam. In one of the houses the small and seldom seen *Tetranema mexicana* is flowering, the habit of the plants and flowers somewhat resembling *Violets*. In the nursery the *Leatherwood Tree*, *Dicra palustris*, is covered with small yellow flowers. It is a dwarf shrub found growing in the marshes of North America, and is suitable for planting in moist positions. Its wood is very tough, hence its popular name. The bark is acrid and cathartic, and the fruit is narcotic like *Stramonium*. *Cornus mascula* is also flowering freely, and the fine trees of *Magnolia conspicua* will, weather permitting, shortly be in great beauty.

— MR. H. B. ELLWANGER, of the Mount Hope Nurseries, Rochester, N.Y., in reviewing the ROSES OF THE PAST TEN YEARS, adjudges Catherine Mermet and Marie Van Houtte as the most refined in the class to which they belong. "Were I," writes Mr. Ellwanger, "unfortunately compelled to grow only two Roses of the class for cultivation I should without hesitation choose those two. Among many jewels they with *Maréchal Niel* are the fairest of the fair."

— MR. CHALLIS, late gardener at Cheveley Park, Newmarket, has been removed to Bute House, Campden Hill, Kensington, the Duke of Rutland's London house. Mr. Cox has been sent to Cheveley and is now gardener there.

— It is a little surprising that the distinct and early-flowering RHODODENDRON PRÆCOX is not more extensively planted in shrubberies. It is very early, hardy, and attractive. Mr. G. F. Wilson recently exhibited sprays at South Kensington of a longer-flowered variety named *R. præcox superbians*, which we also observed quite covered with purplish lilac flowers in Mr. Wm. Paul's nursery at Waltham Cross. It is a valuable early-flowering shrub, somewhat resembling Messrs. Veitch's fine variety *Early Gem* which we have previously

alluded to. These hardy and precocious Rhododendrons are as useful in shrubby borders in early spring as are plants of the small *Azalea amoenae* and its improved varieties for greenhouse and conservatory decoration.

— ONE of the brightest double PELARGONIUMS that we have observed recently was in the possession of James McIntosh, Esq., at South Kensington on the 19th inst. The colour is crimson magenta, and the truss and pips are very fine. Mr. McIntosh speaks highly of this variety, which he had from Mr. Cannell under the name of Joseph Somers.

— REFERRING to the BAMBOO IN ANNAM, *Galignani* observes that this eastern kingdom possesses immense forests, which contain many sorts of trees capable of supplying the most valuable wood, and some day, when the commerce of those distant regions is more developed, they will become the object of a large trade. But the vegetable production most esteemed by the poor and oppressed people is unquestionably the Bamboo. Every house and village, from the seashore to the mountains, is furnished with its belt of this reed, and, to judge from the manifold usages to which it is applied, they have by no means a superabundance. The young shoots are eaten as a vegetable; the natives make of it paper, string, and cord, trellis-work, textile fabrics for dress and all other domestic purposes, baskets, mats, and partitions; they construct of it boats, and utensils for cooking which will stand fire, pipes and pipe stems; boxes and coffers lacquered, of great solidity and very elegant; they form their hats of it, and the best arms of the country are bamboo clubs; its thorns and thick hedge are the strongest defences of the dwellings, and portions of it are sharpened and driven into the ground in front of the fortresses to form stockades, and every soldier on service is bound to be furnished with a certain provision of such pieces; sonorous instruments are made from it for signals as well as bridges to cross torrents, and finally houses are built with it. From the above enumeration some idea may be formed of the quantity required by a population numbering between thirty and forty millions.

— WE have received the first number of a work by Mr. Thomas Christy, F.L.S., entitled "NEW COMMERCIAL PLANTS, with directions how to grow them to the best advantage," also a number by the same author of "Forage Plants and their Conservation," the object of which appears to be to further the cultivation of the Caucasian Prickly Comfrey (*Symphytum aspernum*) which is spoken approvingly of both on account of its productive properties and nutritious qualities.

PRUNING FRUIT TREES.

SOUND and well-timed remarks by "A MIDLAND COUNTIES FRUIT-GROWER" on this important subject appeared on page 121. I quite agree with your correspondent that where the greatest bulk of fruit is the object in a limited extent of time, the safe practice is to "put much trust in Nature" and to employ the knife sparingly.

At no period of the year than the present can more important lessons be learnt on the pruning of fruit trees, and especially by comparing healthy young trees that have been pruned in the orthodox manner by the side of other healthy trees that have received little or no aid from the knife. The regularly pruned trees may be rigid models, of symmetrical outline, but they do not contain half the quantity of blossom buds, and are not much more than half the size of trees that have been left pretty much to Nature.

If healthy examples of pyramid Pear trees, for instance, that have not been pruned—that is, not having had their branches shortened-back for the past three years, are examined now they will be found bristling with white, fat, swelling blossom buds; while trees, as a rule, that have been systematically mutilated contain comparatively few fruit buds in proportion to those on the unpruned trees. Your correspondent has well observed that if the branches of the trees are left unshortened that natural spurs will form on them; but if two-thirds of the length of last year's shoots is cut off the result is not blossom, but another mass of shoots similar to those cut off. This is what the fruit-grower means by growing crops of "flower stakes." If the long young shoots of unpruned Pear trees are examined now hundreds of fruit buds will be found on last year's shoots as well as on the two-year-old wood. It is instructive to notice, too, the particular portions of the shoots that contain the greatest number of blossom buds. Take a shoot from 18 inches to 2 feet in length, examine it, and the

9 inches at its base will contain nothing but wood buds, which no amount of pruning can convert into blossom buds; but the remaining portion of the shoot, and especially near its point, will contain many blossom buds. Now had pruning been resorted to in the common manner, and before the blossom buds were so recognisable as they are now, precisely that part of

Fig. 33.—*Erica andromedaeflora*.

the shoot which produces them would have been cut away, while exactly that portion, the lower 9 inches of the shoot, which does not produce fruit buds, or at least is a long time in doing so, would have been retained. What for? Answer, To grow more wood.

It is impossible to form even an approximate estimate of the enormous annual destruction of fruit-tree blossom by the popular system of shortening the shoots. The clean healthy growths of hardy fruit trees, such as Apples, Pears, Plums, and Cherries, are systematically shortened because it is supposed the wood removed is not ripe. But ripe or unripe, it is the wood that produces the most fruit, and, as if affording

a perennial rebuke to pruners, continues producing it for an indefinite period of time—a great number of years. Is not the wood-ripening hobbyhorse of hardy fruit trees being ridden too hard? Are there no fallacious notions existant in reference to the ripening process of the wood of hardy trees? Does a shoot that we regard as only partially ripened for ever remain so, or does it complete its maturation the following year? That is a question worthy of a little consideration. Nine-tenths of pruners act as if they believed that a shoot that was not fully matured in 1877 could not become additionally mature in 1878, therefore the amputating remedy is applied and the shoot is severed from the tree. I believe the ripening of wood to be a slower process than that, and that if its maturation is only partially effected during one year it is completed the next. I wish some such practical gardeners as Messrs. Taylor, Luckhurst, Abbey, and others, also some Rose-growers, would state their opinions on that point, which is one of the few things in gardening practice that has not received the attention it merits, and one which has a direct and important bearing on the fruit supply of this country.

In connection with fruit trees which have been left pretty much to Nature another point is worthy of attention. Such trees, say at five years from being planted, not only produce an infinitely greater amount of blossom than trees that have been rigidly pruned, but the unpruned trees usually set their fruit much better than do the mutilated trees. I could point to a garden, or rather to two gardens side by side; both of them are large, and contain many hundreds of fruit trees. In one garden the trees are pruned systematically, and have, in fact, carloads of "flower stakes" cut from them annually. In the other garden the pruning is almost limited to thinning out the branches, scarcely a shoot ever being shortened. If it were possible to ascertain the amount of fruit that has been gathered from the two gardens in question, say during the last ten years, I do not hesitate to say that, taking a given number of trees at the same age from each garden, that five times the quantity has been gathered from the unpruned that has been gathered from the closely pruned trees. This is not entirely attributable to the blossom-bearing condition of the trees, but there is an important difference in their fruit-setting properties. I have seen the trees in one garden practically barren when those over the fence have been heavily laden with fruit. Both were subjected to the same climatic influences, and were growing in soil of precisely the same nature. I attribute the difference, to a certain extent, to the different physical condition and character of the trees. In the unpruned trees Nature had determined the proper and healthy balance between root and branch; but in the pruned trees the roots were, to speak paradoxically, in the ascendant. When this is the case—I mean when root-action is excessive and the growth of the trees is very exuberant, as is generally the case with young and severely pruned trees—the blossoms often fail to set satisfactorily.

That the pruning of fruit trees has been and is carried out too severely when the object is to provide a maximum quantity of fruit within a minimum extent of time is an impression that has become fixed in the minds of many practical cultivators; and the subject is at least of sufficient importance to receive the attention of those engaged in growing hardy fruit to meet a large home-consumptive demand, or for market purposes. It may be well to prune young fruit trees rather closely for the first three or four years after they have been grafted in order that they may form a stout framework of branches; but after that, if the supply of fruit is of greater moment than an artificially symmetrical shape of tree, then the pruning should be nearly or quite limited to the thinning-out of the branches, so as to induce the formation of natural spurs.—J. W.

CULTURE OF THE CINERARIA.

Or spring-flowering plants the Cineraria will always stand in the foremost rank for decorative purposes. Great improvements have been made of late years both in the form and colour of the flowers. The petals are now of great substance, and the colours are very bright and varied.

The second week in April I have found to be the best time for sowing the seed for early blooming, and the latter end of May for late blooming. The seed should be sown in pans, in a mixture of equal parts of loam and leaf soil, with a little sand to keep the soil open. The compost should be pressed in moderately firm and have a gentle watering. Sow the seed thinly, and cover it very lightly with a little fine soil. Place a layer of damp moss on the surface to counteract the drying of

the soil, which is much preferable to watering, removing the moss as soon as the seedlings are discernible. Place the pans in gentle heat until the seed has germinated, when they must be removed to a cool house or frame, placing them close to the glass to prevent the seedlings being drawn. Care must be taken also to shade them from bright sunshine. When large enough to be handled prick the seedlings into pans or boxes, using the same kind of soil as the seed was sown in, with a little very much decayed cow dung added. Keep them close for a few days until they have a fair start, after which an abundance of air must be given. When the leaves touch pot-off the plants into 60-size pots and keep them close to the glass. A position should be given where they do not have the direct action of the sun, so as not to have the shading material on too long. The next shift will be into 48 or 32-sized pots, using two parts of yellow loam, one part of leaf soil, and one part of decayed cow dung, with a little river or silver sand added. A cold frame with a north aspect will then be the best place for them, and they must be carefully watered. If it is desirable to make large specimens repot the plants into 16-sized pots, using the soil more lumpy. During fine nights in summer the lights should be drawn off for the plants to have the benefit of the night dews. The plants should be stopped once, which should be done before their final shift. Place a piece of string under the rim of the pots to which the shoots can be secured, so that the air can circulate well amongst them. The tying also keeps the plants dwarf and of good shape.

For forming specimens it is the best plan to have named sorts or selected seedlings, which must be increased by cuttings or offsets. After the plants have flowered cut them down. A portion of the surface soil must be removed and be replaced with some rich compost, which the offsets will readily root into, when they must be taken off and be treated as seedlings. When the pots are filled with roots a little liquid manure should be given. When there is danger of frost the plants should be removed to an airy position in the greenhouse. Some growers recommend keeping them in a cold frame, but I have found the foliage liable to damp off, as they cannot have the requisite amount of air in frames, which have to be covered up a great deal to exclude frost. Those plants which have been treated so as to form specimens should be tied into shape before they come into bloom, so as to give the flowers and foliage time to assume their symmetrical position. Some of the plants will sometimes go off, which some attribute to the grower's carelessness, but which I think is a disease, as during some years I have not lost one plant, whilst in others I have lost several. Fumigate frequently as a preventive of green fly, which is much better than waiting until the plants are infested.—A SOUTHERN GROWER.

PORTRAITS OF PLANTS AND FLOWERS.

HOODIA BAINII. *Nat. ord., Asclepiadaceæ.*—"This very interesting addition to the Cape Flora was originally brought by Mr. Thomas Bain from Uitkyk, on the road through the Karroo to Beaufort West, in the autumn of 1876, and given to Sir Henry Barkly with flowers preserved in spirit. Subsequently Mr. McGibbon, the Curator of the Cape Botanic Garden, obtained specimens of the same plant from Mr. Lycett of Worcester, South Africa; and one of these was brought by the former to this country on his recent visit, and presented to the Royal Gardens, where it flowered in July of last year."—(*Bot. Mag.*, t. 6348.)

JASMINUM DIDYMUM. *Nat. ord., Olceæ.*—"This very pretty Jasmine is a native of tropical and subtropical Australia, and extends into the Pacific, inhabiting Lord Howe's Island, New Caledonia, the Fijis, and Timor; in all these countries frequenting sandy ridges and cliffs, &c., near the sea. It forms a very elegant hothouse climber, with bright green glossy leaves and pendulous festoons of white flowers, which appear in midwinter. I think it was sent to Kew by Mr. Milne, the collector in Captain Denham's surveying voyage to the Pacific about twenty years ago, since which time it has been known in the Palm house at Kew as an old inhabitant."—(*Ibid.*, t. 6349.)

RONDELETIA ODORATA var. *BREVIFLORA.*—"This has been long cultivated at Kew under the name of *Rondeletia speciosa*, a plant first published in Loddiges' 'Botanical Cabinet,' with a wretched figure and no botanical description, and which is said closely to resemble Jacquin's violet-scented *R. odorata*, but to differ in not having the slightest scent. Now the plant

at Kew figured is scentless, and has much smaller flowers with a far shorter corolla-tube than either the native herbarium specimen or the published figure of *R. odorata* and *speciosa*, and must hence be either a new species or a variety of one or the other of these."—(*Ibid.*, t. 6350.)

PTEROSTYLIS BAPTISTII. *Nat. ord.*, Orchidaceæ.—"The terrestrial Orchids of Australia, though celebrated both for their beauty and singularity, have rarely been flowered in this country, and more rarely kept after flowering. Amongst those who have achieved success in the culture of one kind at least is Mr. Williams of the Victoria and Paradise Nurseries, who in January last flowered a large stock of this very remarkable species. In repose the lip hangs forward against the cleft between the united lateral sepals, but on being irritated at its base it springs up and becomes embraced as it were by the projecting wings of the column, and is thus brought almost in contact with the anther. An insect entering or falling into the base of the flower irritates the lip, which catches it between its face and the column, and in its struggle to escape the insect passes upwards over the stigma, and sweeps away the pollin-masses. These it may take to other flowers, when the same process results in a portion of the pollen being retained on the stigma. Mr. Fitzgerald, who observed the process on a many-flowered species of the genus, remarks that notwithstanding the complexity of the arrangement, very few flowers comparatively seemed to be fertilised. *P. Baptistii* is a native of the neighbourhood of Sydney, where it was found in a 'tea-tree' swamp by Mr. Baptist, and transferred by him to his nursery gardens."—(*Ibid.*, t. 6351.)

XIPHIUM PLANIFOLIUM. *Nat. ord.*, Iridaceæ.—"This is a most peculiar and unique Irid. It has very large, generally single, delicate lilac flowers, that rise without any stem from the centre of a number of leaves, the showy part of the flower being made up of the large stigmas and large outer segments of the perianth, the three inner segments being very small and spreading from the top of the long perianth-tube. It is widely spread through the south of Europe, extending from Portugal to Sicily, and reappearing across the Mediterranean. As it flowers from September to January it can only be satisfactorily grown in England under cover, and lately it has been imported and sold in considerable quantity to be grown in coloured glasses on mantelpieces and in windows, like Hyacinths. It has been known to botanists for the last two hundred years, and there is perhaps hardly any other bulbous plant that has received so many different names, as it has had six different specific names, and the small group of bulbous Irises to which it belongs has been characterised as a genus five times by as many different authorities."—(*Ibid.*, t. 6352.)

EXPERIMENTS WITH SCARLET RUNNER BEANS.

MY soil being rather light and not exactly suited to the growth of the Scarlet Runner Beans, and the climate in spring being cold, they did not always succeed very well here. I thought I would try a few experiments to see if more satisfactory results could be obtained by alterations in the mode of cultivation:

In March, 1873, I selected a rather sheltered place in the garden, and had two trenches dug across the border, and some well-decayed manure put at the bottom as though intended for Celery and otherwise prepared, and at the beginning of April I had one trench planted with Scarlet Runner Beans, and on the same day I had some Beans sown in a box and started in a cool vinery. Those in the vinery soon came up, and before long were in danger of getting too much drawn up if allowed to remain in the house; I therefore had them moved outside with the protection of a handglass, and there they remained for some time. When the weather became decidedly fine at the end of April I had the Beans in the box planted-out in the other trench.

During the month of May the Beans in both trenches were protected at night by having some sticks driven in on each side of the trench and mats or some other covering thrown over every night. There was much frost that year in May, and the covering had to be persevered in; and when all danger was over from frost dry weather followed, which rendered it necessary to give a good soak of water in the trenches sometimes; but the Beans grew and flourished wonderfully and produced an abundant crop, which supplied the wants of a large family from the middle of July until the first week in November, and were considered the two best rows in the neighbourhood.

In 1874 the experiment was repeated in exactly the same manner and on the same ground. There was no frost to speak of in May that year, and consequently very little trouble in protecting the Beans, and no watering required in spring. The Beans flourished very well and became two very good rows of Scarlet Runners, and the produce was very fair but not quite equal to that of the previous year, the long period of dry weather at the end of the summer shortening the produce in the autumn.

In the following year, 1875, the experiments were continued with very satisfactory results, and have been so continued every year to the present time and always on the same ground. I will now make a few general remarks. There is not much difference generally between the transplanted row and the other. The former is generally about two or three days earlier, and the lower part of the plant comes into blossom rather earlier. I at one time came to the conclusion that there was no particular advantage in raising the plants in the vinery, and both rows might be planted outside; but subsequent experience showed this to be wrong, for last year the seed in the vinery failed, and I did not re-sow, trusting to the row outside, but that also failed, as I subsequently discovered in consequence of the seed having been kept in too warm a place, and I had to plant again, which threw me a few days behind my neighbours instead of being a few days before them. Anyone having a cool vinery or other glass available I would recommend to make use of it, and then they will be sure of their plants, because if the seed is good the Beans very soon come up and there is ample time to plant again if necessary. Anyone following this method of planting must be prepared to afford protection during the month of May. Small angular frames, or Acme frames, are very good for this purpose, but they should be taken off every fine day and put over again at night. This may appear rather a trouble, but if the garden is close at hand and the uncovering done every morning directly after breakfast it comes as a matter of course. Fir branches I daresay might answer the purpose, and the Beans being in a trench rather below the surface of the soil renders the protection easier. One year I had some old window-blinds as a covering, and they answered admirably.

One thing I ought to call attention to: I have mentioned the end of April as the time for transplanting the Beans from the box, but it is only done then in case the weather is genial; if it is not it is delayed until the weather is more favourable, but never later than the 12th of May, which is the time people generally plant Scarlet Runner Beans here, and if you put in well-established plants instead of Beans it gives you a considerable start, and the earliness is not the only advantage—you have a larger crop from the same space of ground.

In cases where the soil is strong or a good loam trenches need not be made, or very shallow ones, but a little manure forked in the rows before planting would be of service. I intend now the first opportunity to begin throwing-out the trenches for the sixth crop on the same land.—*AMATEUR, Cirencester.*

WALLFLOWERS.

"WHY write about Wallflowers now, since it is quite too late for transplanting them and the plants are just commencing flowering?" That is a very natural question, and likely to be asked by those who estimate, and rightly so, the value of an article in the Journal in proportion as it is seasonable—that is, appearing at a time and in a form to be useful.

It is always more or less disappointing to readers thirsting for information to find a communication admirable in itself but written two months too late to be of real service until another year. For instance, it is not consoling to read excellent instructions in February on the cultivation of a particular crop which we are told must be raised from seed sown in the autumn, or to find information given in October that such a plant to be grown successfully must be raised from cuttings inserted in August. However sound the practice may be that is detailed, and however ably an article is written, it cannot fail to be much less acceptable to the majority of readers if it appears at an unseasonable time.

I write on Wallflowers now, even if they are just expanding their flowers, and notwithstanding that it is too late for transplanting them, because to have them in the finest condition as early in the year as possible the seed must be sown or the cuttings must be inserted as nearly as possible a year previously—that is, if a grand display is required to commence in March,

1879, the seed must be sown in March, 1878. I submit, therefore, that my notes on this sweet and cheerful hardy flower are at the least seasonable.

No one who has not seen the common single Wallflower, as represented by the dwarf dark red and compact golden yellow varieties as grown when raised from seed sown early and the plants having been timely and sufficiently thinly planted, can form any idea of the real value and beauty of this charming simple flower. Too often the seed is sown in June or July at the same time that seeds of Sweet Williams, Canterbury Bells, &c., are sown, but that is altogether too late for producing satisfactory plants of Wallflowers. When late sowing is practised the plants have to be grown as rapidly as possible in rich soil to enable them to attain a fair size before winter. That practice is decidedly wrong, for such plants are so tender and succulent in their nature that many of them are killed when severe frost ensues, and if they are not killed they cannot flower early, and unless they do this more than half of their value is lost. The seed of Wallflowers should be sown at the same time that Onion seed is sown, and in the same manner. The plants have then a long period for growth before them; and if they are planted in firm ground and in an exposed situation they will be dwarf, stubby, woody, and hardy, and will commence flowering in the earliest days of spring.

The seed should be sown very thinly, and be covered about a quarter of an inch deep with light soil. When the seedlings are large enough to be handled they should be transplanted 4 to 6 inches apart in nursery beds, and as soon as the foliage meets in the rows the plants should be replanted not less than 15 inches apart in firm and not over-rich soil in the most sunny and exposed situation at command. They seldom or ever require to be watered. When established pinch out the tops about 4 inches from the ground; they will require no further stopping, and only need to be kept scrupulously free from weeds to enable plants being produced by the autumn more than a foot across and about 9 inches high or less, and with foliage resting on the ground.

Such plants are very valuable for filling vacant beds in the winter and for planting in lines on borders, also for intermixing with dwarf shrubs in the marginal borders of pleasure grounds. Wallflowers are everybody's plants. They brighten and cheer the homes of cottagers and suburban residents, and they are worthy of being grown by thousands in the gardens of dukes; indeed they are so grown at Belvoir, Cliveden, and other notable gardens. It is a little surprising that plants so easily raised, and which are always so much admired when well grown, are not more extensively cultivated in public parks, gardens, and cemeteries; but perhaps the managers of such places have enough to do to provide plants for summer bedding, which they usually carry out so creditably.

Wallflowers are so bright and cheerful when flowering in masses, so fragrant and welcome, the seed is so cheap, and the cultivation of the plants so simple, that a plea for their extended culture at this the time for providing a stock may perhaps be deemed worthy of a place in your columns. I will allude to raising double varieties from cuttings on a future occasion.—A SPRING GARDENER.

THE BOTANIC GARDENS, KEW.

ALTHOUGH there may have been some rule in existence by which those identified with the objects which this garden was established to promote might have admission to the gardens previous to the recognised hour of opening, I think it very probable that few were cognisant of the fact made known in your last issue on page 200, and ratified by the authority of Sir Joseph Hooker on page 209. It may be taken for granted that the facilities extended to botanical students and professional gardeners will be highly appreciated, and Kew will not only be rendered more popular than before but more useful.

Having to visit Kew Gardens occasionally I have more than once experienced the courtesy of the officials in charge there by being readily admitted before one o'clock on the presentation of my card. Although I do not enjoy the personal acquaintance of either the Director, Curator, or anyone in authority, I can say that never have I experienced the slightest difficulty in gaining entrance as soon as my object was known. It is true that when I was admitted before the stipulated time I felt as if it was on sufferance, and that I was every time receiving a favour and not exercising a right, and consequently I attended as seldom as possible, and not so often as my re-

quirements demanded. Now that I feel I have the right of entrance before one o'clock the pleasure of a visit will be greatly enhanced. But before exercising the privilege officially accorded me I desire to join in the expression of acknowledgment which I feel you have justly recorded of the uniform courtesy of the officials of the gardens. I also wish to acknowledge the civility of the *employés* and their readiness to give any information in their power by not only answering questions promptly, but, what is always appreciated, pleasantly. I have visited many gardens public and private both in this and other countries, but I have never found one so replete with instruction on matters botanical and horticultural as this great and excellently conducted establishment. To make it a place of popular resort—a mere pleasure garden, open to all comers from morning till night, would simply destroy the high character that it enjoys as the head quarters of scientific horticulture in this country.—EAST ANGLIAN.

CAPE HEATHS.—No. 3.

MARCH.

THE pots and soil having been duly prepared we next come to repotting, and in this matter care and attention are

Fig. 34.—*Erica colorans superba*.

necessary. Never allow Heaths as young plants to become pot, or, to use a better expression, root-bound; yet we do not appreciate the one-shift system, but would warn the amateur against giving the plants too large a shift, for when this is done the soil is very apt to become washed out or sour before the roots can occupy it, and in the second place the effect of overpotted plants is most unsightly; therefore we say by all means let the shift be such as will allow of a moderate amount of soil to be added. The roots of *Ericas* should be disturbed as little as possible, but the old drainage should always be removed. In potting it must be remembered that the firmer the new soil is made the better; indeed, loose potting, such as that adopted for softwooded plants, is sure death to Heaths. There has been much controversy respecting

the proper season of the year for repotting, and our experience goes to prove that the spring is by far the best time, and the middle of summer the worst. We have potted with satisfactory results in autumn, but, as before remarked, the spring—that is, during the end of March and month of April—we prefer to any other time. These plants do not require periodical potting, and large specimens may be kept many years in the same soil and pot in perfect health if proper attention is bestowed upon them in the matters of air, temperature, and water.

The following are some of the best kinds which serve to keep the greenhouse gay at this season :—

E. andromedæiflora.—An arborescent species of great beauty. Leaves arranged in threes, subulate, incurved and acute, deep green. Flowers nearly terminal, nodding, and springing from the axils of the leaves, globose, thick, and wax-like in texture, delicate flesh-colour throughout. (See fig. 33, page 223.)

E. andromedæiflora alba.—A variety with pure white flowers, extremely beautiful.

E. andromedæiflora rosea.—This variety is scarcely so robust in growth as either of the preceding, and differs from the normal form in having the corolla suffused with rich rosy red.

E. colorans superba.—A shrubby erect-growing softwooded kind, having linear obtuse downy light green leaves arranged in fours. Flowers produced in clusters towards the ends of the branches, and forming dense racemes of tubular bell-shaped pendulous blooms, which are pure white in a young state, but change with age to rose colour.

E. ignescens.—This is a showy free-flowering plant. Leaves linear, smooth, dark green, and arranged in fours. Flowers club-shaped, solitary, and terminal, bright reddish scarlet in colour.

E. regerminans.—A twiggy, compact, softwooded plant of free growth. Leaves arranged in fours, linear, obtuse, and dark green. Flowers small, bell-shaped, produced in clusters at the ends of all the branches, pale purple in colour, and sweet-scented.

E. fastigiata.—Leaves arranged in fours, linear, smooth, and deep green. Flowers also arranged in fours, terminal, swollen at the base, and pure white.

E. Linneæana superba.—A robust-growing variety of great beauty. Leaves arranged in threes, linear, obtuse, and villous. Flowers large, tubular, hirsute, terminal on the small branches, forming long dense racemes; lower portion of tube rosy purple, mouth white.

E. canaliculata.—Leaves arranged in threes, linear, obtuse, plain above, channelled below, and deep green; the footstalks long and coloured. Flowers nodding, bell-shaped, arranged in threes at the ends of the small branches, pale purple in colour.

E. canaliculata minor.—As the name implies, this is a smaller plant than the preceding, as also are the flowers, which, however, are deeper in colour than the type. It is a desirable neat-growing much-branched plant, possessing great beauty.

E. pedunculata.—A handsome plant, having linear, obtuse, hairy, deep green leaves. Flowers rosy purple, nodding, ovate, supported upon long coloured footstalks, and produced in terminal umbels.

E. campanulata.—An elegant slender-growing plant. Leaves subulate, smooth, and arranged in fours, light green. Flowers pendant, usually solitary, bell-shaped, and clear yellow. (See fig. 35.)

E. persoluta.—Leaves linear, obtuse, light green. Flowers small, bell-shaped, produced in great profusion upon all the small branches, and forming long and dense racemes of a deep bluish colour. There are two varieties of this plant—viz., *alba* and *rubra*, the former producing pure white, and the latter deep red flowers.—W. H. G.

BLUE FLOWERS FOR BEDDING.

WE are now very rich in blue-flowered plants for bedding purposes. The following is considered a good selection. Commencing with very light shades there is *Countess of Stair Ageratum*, rather washy-looking but distinct. Of a darker shade, much like the old dwarf *Lobelia pumila grandiflora*, is a seedling *Ageratum*. I have grown it two years, and I am again testing it this season; it is of a low spreading habit, averaging 4 or 5 inches in height. *Lobelia magnifica* is one of the best I have grown. *Lobelia St. Martin's Blue* of last year's introduction I think likely to hold a high position; I shall plant over a thousand of it this year. Indispensable plants are some of the *Violas*. Perfection is still one of the best;

Duchess of Sutherland, a bluish mauve, is being tried this year; *Admiration*, one of the darkest, inclining to violet, is also on trial; both are thought very much of. *Purple King* *Verbena* is one of the finest of bedding plants, and for large beds or broad masses in borders nothing can outlive *Verbena venosa*. These can be one and all highly recommended as good in the particular shades they represent, and selections may be made from them according to the requirements of your readers.—R. P. B., *Tynninghame*.

JUDGING ROSES.

[Written by W. Wilson Saunders, Esq., F.R.S., and read on March 5th, 1878, before the General Committee of the National Rose Society.]

FOR exhibition purposes the character and capabilities of the Rose seem to be well understood, seeing the numerous

Fig. 35.—*Erica campanulata*.

beautiful examples of good flowers which are constantly brought forward at the various exhibitions held throughout the country. I have thought, however, that the rules which should guide the judges in forming an opinion of the Rose as a show flower not sufficiently determined and not considered as they ought to be, and that it would be well for the National Rose Society carefully to go into the subject, and to form a code of plain rules for the guidance of the judges appointed at the shows held by the Association.

A first-rate show Rose, according to my views, should have the following qualities :—1, Large size; 2, Good shape; 3, Petals well formed and arranged; 4, Colour or colours good and clear; 5, A perfume strong and agreeable. Of these five qualities I place—

1st, The size, for I think it evident that, all other qualities being satisfactory, the larger surface we have to rest the eye upon the better.

2nd, The shape must be considered as a very essential character, whether it be cupped—that is to say, with petals more or less erect; or globular, with petals more or less incurved; or expanded, with petals more or less horizontal. Of these shapes I prefer the cupped, as then there is a fair view of both sides of the petals, while in the globular we see

chiefly the outside of the petals, and in the expanded chiefly the inside of the same.

3rd, The character of the petals should be carefully observed, and they should be well formed, of good substance, and symmetrically arranged from the circumference to the centre, well filling up the central area, and having the outer range of petals—which may be called the guard petals—large, broad, well shaped, and well coloured; these guard petals being so apparent in the cupped and globular-shaped Roses.

4th, Colour is a quality which will find admirers, whether it be pale or brilliant, provided it be good and pure of its tint. No Roses with dull colours, or run colours, or partly faded colours should be admitted as first-rate show flowers.

5th, Perfume, which has been sadly neglected in show varieties of the Rose, should now be insisted upon, and that it should be strong and agreeable. There are numerous good Roses which can be exhibited with fine perfume, and these should have the preference, the other qualities being satisfactory.

So far as regards show Roses; but the Rose for decorative purposes, whether in the garden or elsewhere, is I think at the present time more worthy of consideration, and here the subject of the Rose as a show and decorative flower much widens out, and we must look to the future for varieties which will come up to the standard of excellence which I shall endeavour to point out. If we look to the species and varieties of the Rose which are growing in our English gardens at present we shall find kinds having one or more of the following qualities:—1, Good and nearly perfect flowers; 2, flowering the whole summer and winter; 3, with good evergreen leaves; 4, having a bushy or trailing habit of growth; 5, constitution in every respect hardy; 6, growing well on their own roots. Here, then, is what we have to work with to build up an ideal standard-of-excellence Rose, and this Rose should in my view have at least the following qualities:—

1, The flowers should be good and perfect, whether double or single; if double, with the qualities I have pointed out for show Roses; if single, well and regularly formed, large, and lasting.

2, The flowers should be produced from spring to autumn without intermission.

3, The plants should have numerous evergreen leaves of good size.

4, The plants should have a bushy or trailing habit of growth, so as to be useful for covering walls, trelliswork, poles, &c.

5, The plants should have a good constitution, be free growers on any fair soil, and be capable of bearing our severest winters without injury.

6, The plants should grow freely on their own roots.

In all this I am looking for a combination of qualities which are not now to be found in any Rose under cultivation, and must be obtained by judicious and patient crossing of the various varieties or species at the command of horticulturists. The ideal Rose of excellence I have ventured to sketch out I am fully aware will be very difficult to obtain, and probably a long time will elapse before we see it; but I do not in the least despair of its being produced hereafter, knowing the intelligence, zeal, and energy of our horticulturists, and what they can bring to pass if they set earnestly about it.

How the National Rose Association can best assist in bringing about a really good decorative Rose I do not clearly see, but I think good prizes might be offered for Roses having as many of the qualities I have mentioned as can be from time to time produced in the same variety. I know of no flower so generally a favourite as the Rose, and none in which I take so much interest or wish to see progress so as to be still the flower of flowers in the estimation of the public, and therefore I sincerely hope the National Rose Association will see some way of breaking up new ground in the field of Roses by encouraging new and approved varieties tending towards a perfect decorative Rose.

THE LAST OF THE OAKS OF BIRNAM.

BIRNAM has been rendered classic ground by the immortal Shakespeare, and in ancient times formed part of the Royal Forests of Scotland, being then covered with a vast forest of Oak and probably Scotch Fir. The "last Oaks" are, according to tradition, remnants of this ancient forest, and must at this date be close upon one thousand years old. These venerable monarchs are three in number, consisting of two Oaks and a Plane (Sycamore). One Oak and the Plane are growing

close to the river Tay on the south bank, and immediately behind the Birnam Hotel, and about 800 yards east of Dunkeld Bridge. On account of their remarkable antiquity they are objects of great interest to the numerous tourists and others who frequent this romantic and picturesque neighbourhood.

The girth of the Oak at 5 feet from the ground is 18 feet, and that of the Plane, which stands 80 feet west of the Oak, is 19 feet 8 inches. When the celebrated traveller Dr. E. D. Clarke visited Dunkeld early in the present century he examined and measured these grand old trees, and seems to have been so impressed with their gigantic proportions and enchanted by their magnificent surroundings that I cannot do better than quote his remarks—"To enrich this noble scene the finest trees are seen flourishing with the greatest redundancy. How weak and groundless are the expressions of Johnson respecting Scotland and its timber, where one beholds this luxuriant valley proudly decorated with majestic Oaks, Sycamores, Limes, Beeches, Maples, and all the glories of the forest! I measured a single Oak close to the ferry, and found it to be 17 feet in girth, and near it stood a Sycamore of much greater magnitude." It will be seen by these measurements that the Oak has only added a foot to its girth in about seventy years. The next Oak of interest, which is said to be of the same age, is growing two miles to the south-east of the latter two trees, and is 10 feet 4 inches in girth, with a high and wide-spreading head. It is called the Hangedmen's Tree, and was used in olden times by the lords of Murthly for hanging thereon thieves and other offenders against the laws; hence the name. In the year 1094 King Duncan had his camp about half a mile from where this tree stands, and also held courts of justice on a small hill to the south-west of it. Some even assert that he also hanged his miscreants on this very tree. The whole of these trees lay in the line of march of the English army, who came under the command of Gerard Earl of Northumberland to place Malcolm on the Scottish throne instead of Macbeth, and branches may have been taken from off these identical trees to disguise the army when on its way from Dunkeld ferry (whither they went to meet allies from the north) to Dunsinane Hill, the stronghold of Macbeth. The witches, whom he regularly consulted, had advised him to fortify this hill, and here they promised him perfect security until "Great Birnam Wood should come there against him"—

"Be lion-mettled, proud, and take no care
Who chafes, who frets, or where conspirers are;
Macbeth shall never vanquish'd be until
Great Birnam Wood to high Dunsinane Hill
Shall come against him.

Macbeth. That can never be:
Who can impress the forest, bid the tree
Unfix the earth-bound roots?"—SHAKESPEARE.

It is further stated that the Sycamore and Oak were planted for the lord and lady of Murthly to tie their ponies to while they attended worship in St. Jerome's chapel, which was situated on the top of a small knoll on the north side of the Tay. Twenty years ago the descendant of the celebrated fiddler, Neil Gow, told me that while Neil (who was passionately fond of Highland whisky) was away on the hill of Birnam at a drinking and fiddling bout in some of the smuggling bothies which then existed, the night turned out very stormy, and Neil could not find his way home, but stayed till a late hour in the morning in the bothy. He at last ventured out and made for the ferry, but on account of the storm the ferryman, who lived upon the opposite bank, could not hear him, so Neil sat down at the foot of the Oak above referred to, and slept so soundly under the soothing influence of the "mountain dew" that he was only awakened by the river, which had risen rapidly, rushing over his legs, and was almost swept away by the rising flood. Surprised and thoroughly aroused by his dangerous position, he was quickly brought to his senses, when he found that he had missed his way and was at the wrong ferry! As soon as he got home he is said to have composed the famous tune, "Neil Gow's Farewell to Whisky." So said his friend. Be this as it may, both the locality and the trees are worthy of a visit by those who have the time at their command.—D. MCKENZIE (in *Journal of Forestry*).

AN AMERICAN COFFEE PLANTATION.—The *Prairie Farmer* describes this as follows:—"Coffee culture is very interesting and the growing crop is very beautiful. The trees at maturity are from 5 to 8 feet high; they are well-shaped and bushy, with a glossy dark green foliage, and planted 8 or 9 feet apart. The flowers are in clusters at the base of the leaves, and are small, but pure white and very fragrant. The fruit has a rich

colour, and resembles a small Cherry or large Cranberry; it grows in clusters close to the branches, and when it becomes a deep red is ripe and ready to be gathered. The trees are raised from seed, and do not begin to yield until the third year. In Central America they bear well for twelve or fifteen years, although, in exceptional cases, trees twenty years old will yield an abundance of fruit. The tree is particularly beautiful when in full bloom or when laden with ripe fruit."

NOTES ON VILLA AND SUBURBAN GARDENING.

THE weather has been most opportune for forwarding all operations in the flower garden and pleasure grounds. The shrubby borders have been lightly dug, the weeds and remaining dead leaves being carefully buried as the work of digging proceeded. The edges of the beds have also been neatly and uniformly trimmed with an edging-knife, which has given an evenness and tidiness of finish to the whole work.

The pruning of shrubs and thinning-out those that have grown into each other should now be attended to, for all ornamental trees and shrubs should stand out boldly and have their outlines clearly defined. Laurels and such-like fast-growing shrubs that have become naked at the bottoms should be cut well down, and in the course of a season or two they will be plentifully furnished with young and vigorous shoots. Look over all newly-planted trees and shrubs, for the winds may have caused them to become loose in the soil, in which case the roots must be firmed, and the shrubs, &c., be securely staked. Lawns or grass plots should now be mown. In most places the grass has been steadily growing the whole of the past winter, and it may be necessary to first cut it with the scythe, finishing it off with the machine. Where lawns are patchy let grass seeds be sown in showery weather, there is then more certainty of a speedier germination.

Gravel walks also now require attention. Where the gravel still remains clean and good frequently rolling it is all that can be done, but where moss and other small weeds have accumulated on the surface, the walks should be broken-up with a fork and the moss and weeds be raked off. If the gravel is well rolled with a heavy roller the walks will soon be firm and bright again. In some cases it will be necessary to give a slight covering of new gravel before rolling. Loose walks are unsightly and unpleasant to walk upon, therefore if possible purchase gravel with good binding properties. See also that the drainage of the walks is good. Ample means should always be provided for carrying off the surface water as it falls, particularly after heavy thunderstorms. Gratings should be placed at convenient intervals with deep pans under them for collecting the sand which is brought from the walks by the force of the rains. See that these catch-traps are free from sand, otherwise the drains will be choked sooner or later.

Rhododendrons are well set with flower buds, and some varieties of *Nobleanum* have been in bloom for a considerable period—an instance of the remarkable mildness of the past winter. *R. præcox* and *Early Gem* are also very showy and deserve more general cultivation. We plant numbers of *Gladioluses* amongst our *Rhododendrons*. Now is a good time to plant the corms, also bulbs of *Lilium auratum*. These tall slender-growing plants tower-up above the *Rhododendrons*, and contrast effectually with their fine glossy foliage. *Laurustinuses* are also now very conspicuous; their large masses of snowy-white flowers are indeed grand. *Berberis Darwinii* is also very showy and ought to be in the most limited collections. *Hyacinths* in the open borders are now in almost full bloom and should have supports attached or the wind will snap them off.

Continue inserting cuttings of all dwarf-growing bedding plants that will be required for planting-out for summer decoration. A sweet hotbed and frame will enable large numbers of *Coleuses*, *Iresines*, *Alternantheras*, *Ageratums*, *Lobelias*, *Verbenas*, *Petunias*, &c., being provided. Apply linings of hot manure when necessary to prevent the temperature falling below 65° at night. Cucumbers may be planted in the centre of each light, which will not seriously interfere with the cuttings, and the Cucumber plants will in due time occupy the whole of the frame profitably. Where large quantities of *Alternantheras* are required it is a very good plan to make up a moderate hotbed, place a frame over it, give a covering of a few inches of light sandy soil, insert the cuttings regularly all over this bed, and when struck gradually harden them off. They can be lifted readily with a trowel without receiving the least check; the rootlets of the plants cling to small particles of the manure, and the plants are transferred to the open ground with the greatest ease.

Seed of *Balsams*, *Amaranthuses*, *Ipomæas*, *Thunbergias*, *Primulas*, *Ricinus*, *Nicotianas*, *Cannas*, &c., should now be sown and placed in the frame. *Lobelias*, *Ageratums*, and the *Golden Feverfew* can also be raised in quantity from seed in the same way, pricking-out the seedlings in pots or boxes as soon as large enough to be handled.

It is now about the best time of the whole year for repotting almost all plants requiring a shift. Most plants thrive best in

clean pots, and apart from this the plants will turn out of the pots better and easier when they are again shifted than when they have been placed in dirty pots. *Camellias* when in full flower should be liberally watered with weak liquid manure, and as soon as flowering is over the plants should be removed to a warmer structure, such as a vinery at work, to make new growth and to set their flower buds. The sooner the new growths are formed and the wood becomes matured the earlier will be the supply of blooms another season. The same remarks will apply to *Azaleas*, which should be well syringed to keep down thrips, &c.

Roses in pots that were started a few weeks since will now be sufficiently strong for training into shape. Some small willow sticks are the neatest and best for this purpose. Rub off all weakly shoots from the Roses, and secure the others to the sticks, allowing a fair space for the expansion of the flower buds and for admitting air through the plants. Give occasional doses of liquid manure; soot water is excellent for imparting colour to the foliage and blooms. Bring the plants on very gradually if fine flowers are desired, but at the same time do not admit large currents of cold air, or mildew will be sure to attack the foliage.

WORK FOR THE WEEK.

KITCHEN GARDEN.

HORSERADISH is one of the most neglected of kitchen-garden crops. It is often found in some out-of-the-way corner and is allowed to grow into a mass, the supply being had by taking up a root here or there, which is about all the thinning or management the plants receive from year to year. It is little use attempting to grow this useful root upon the no-principle system. It likes moderately light rich soil, deep and moist but freed from stagnant water. Vegetable refuse is the best application that can be given to the soil for this crop, indeed it succeeds admirably in vegetable refuse alone; but as a large bulk of that material may not be available a portion may be mixed with manure and trenched into the soil. A portion of the crop should be taken up at this time by trenching the ground and clearing it of all roots, selecting those fit for use, which should be laid in behind a north wall, retaining the small clean pieces of 18 inches in length for planting, rejecting all the rest. Plant in rows 18 inches apart and 9 inches asunder in the rows, the entire length of the root being inserted. It will be very fine in two years, and better in one year than the hard woody sticks had in half a dozen years upon the haphazard system. Make a sowing of Savoy—Large Drumhead, Green Curled, and Early Elm, the latter coming in very early in autumn; also Cauliflowers, Brussels Sprouts, and Veitch's Self-protecting Autumn Broccoli, of which we had good heads until the end of February. Plant without delay early Potatoes. We allow 2 feet 6 inches to 3 feet between the rows, and plant between them, after the Potatoes are earthed, Broccoli, Cauliflowers, Savoy, Borecole, or Cabbage for autumn and early winter use. Only the early and dwarf sorts of Potatoes should be grown in gardens.

Forcing Department.—Cauliflowers, Brussels Sprouts, and Lettuces sown early under glass should have gentle waterings and have air freely admitted, being gradually hardened off preparatory to being planted out. Prick out into boxes or frames Celery for the main early crop: the soil can hardly be too rich. Admit air freely to Radishes, Lettuces, Carrots, Potatoes, &c., in frames, watering the crops as required, attending to timely thinning, and earthing the Potatoes as they advance in growth. Tomatoes, which will now be strong in 7-inch pots, may be shifted into the fruiting pots. We grow our earliest crops in 10-inch pots and feed the plants with liquid manure. The drainage should be good, and for compost employ turfy loam with a third of well-decayed dung. Pot firmly, which induces sturdy growth. Place the plants in a light airy situation. A suitable temperature is 60° to 55° at night, with 10° to 15° advance by day, and more from sun heat. Pot off those sown a short time ago, growing them on so as to have strong plants in 6 or 7-inch pots by planting-out time in May. Pot off Capsicums when they show the second leaves, placing three plants in a 3-inch pot, and be careful not to over-water them. Sow Capsicums now for the main crop. Attend to the sowing of Mustard and Cress, introducing fresh roots of Mint and Tarragon, and maintaining the succession of Asparagus by the planting of fresh roots in a frame over a very gentle hotbed. Attend to the sowing of French Beans in pits or frames.

HARDY FRUIT GARDEN.

There is a greater difference in the show of blossom buds by fruit trees than we have before observed. The bloom is not very abundant in Apricots, and the Peach and Nectarine trees are not excessively floriferous. Pears are not very promising on the Pear stock, but those on the Quince are masses of expanding buds. There is a plentiful display of fast-swelling Cherry, Plum, and Apple blossom, with a great prospect of bush fruit. Strawberries are swelling the crowns fast, and promise to be very productive. Peach and Nectarine trees even where blossom is sparse should be protected, for the foliage is very tender, and to protect it is of quite as much importance as securing the blossom and young fruit from frost, as upon the healthy unchecked growth of the foliage depends the permanent well-being of the trees. Unprotected trees

invariably have blistered leaves and their concomitant fungus, and the growth is rendered so late that the wood is imperfectly ripened. It is not unusual when there is little prospect of bloom upon a Peach tree shoot to cut it back to a bud at its base. This is an error, as it induces very strong growths, which are seldom fruitful. We prefer pruning barren and fruitful shoots alike, as by so doing undue vigour is not promoted, timely attention being paid to disbudding and stopping of the shoots to equalise the sap. Proceed with the grafting of Apple and Pear trees. Recently planted fruit trees will be the better for having a mulch of partially decayed manure in dry weather after a good watering has been given.

FLOWER GARDEN.

The best season of transplanting evergreens is when they are commencing growth. Every leaf causes rootlets to be formed, and the warm genial rains which usually prevail early in April aid to a speedy re-establishment of the shrubs. Trees and shrubs from nurseries, owing to their frequent transplanting, which induces the formation of fibrous roots, may safely be transplanted when it would be fatal to move plants of considerable size, grown it may be not very distantly apart and not having been prepared for removal. Standard Rose trees often have the stems mossy; scrape them with a blunt instrument, and scrub them well with a hard stiff brush until the bark is clean. Tea-scented Roses may now have the protection removed and be pruned by cutting away entirely the weak branches, leaving only the best situated of the most vigorous shoots, which should be slightly shortened back. Briar, Manetti, and other Rose stocks may still be grafted. Cut back the stocks, leaving only an inch or so of stem. To this attach the graft, tie tightly, and plunge the plants in a close pit with a temperature of 75°, and shade them until they begin to grow, when light must be gradually admitted. They should be grown steadily on, hardening them off for planting-out at the close of May or early June. Some prefer Roses on their own roots. Those that have been forced and going out of bloom will have tolerably firm wood, of which cuttings may be made of two joints, inserting them singly in small pots in light soil, and placing in moist brisk heat. A sowing of hardy annuals may now be made, such as Mignonette, Sweet Peas, Cornflower (*Centaurea Cyanus*), Sweet Sultan, and others useful for cutting liberally.

FRUIT HOUSES.

Vines.—We are convinced that a longer growing period than is given to late varieties that have to hang through the winter would greatly improve their keeping qualities. Grapes not infrequently shrink after keeping a time, which would be prevented by starting the Vines earlier so as to have both fruit and wood thoroughly ripened. Start late houses without delay, syringing the rods several times a day, and damping the house well every evening. Attend to disbudding, tying-down, stopping, and thinning. Delay in the performance of the operations is to a greater or lesser degree injurious to the Vines. One of the greatest evils in Grape culture is overcrowding. The proprietor and cultivator both desire a great weight of fruit. Avoid that; thin well not only the berries but the bunches, for what is lost in number will be gained in size of berry, superior finish, and quality. Where there is space do not pinch-in too closely, but avoid overcrowding of the foliage. It is better to pinch to one joint beyond the fruit than to leave the shoots longer and crowd the foliage, for the value of foliage depends upon its exposure to light. Be careful in tying down the shoots, when growing vigorously they are liable to snap. Go over them frequently and bring them down by degrees. Young Vines that were cut back at the winter pruning to the bottom of the rafters should have the laterals stopped, but not too closely, so far up the canes as it is proposed to cut them back to in winter, say 3 to 6 feet, but all above that may be allowed to grow at will to promote the formation of roots. The stopping of the laterals will tend to the development of the eyes and the ripening of the wood. Where Grapes are ripening a free circulation of air is essential to good colour and finish, and a comparatively dry atmosphere; but we sprinkle all available surfaces twice a day, so that the drier atmosphere is obtained by freer ventilation. See that the border is duly watered in all stages of growth, particularly when the fruit is swelling, keeping up a good atmospheric moisture by damping two or three times a day, and especially at closing time, with liquid manure. Liquid manure materially assists Grapes which have passed the stoning process, applying it at a temperature of 90°. Admit air in moderation, small quantities at a time, making the most of sun heat by early closing.

Peaches and Nectarines.—When the fruit is stoning avoid sudden changes of temperature, sudden draughts of cold air are injurious. Maintaining the temperature at 65° to 60° at night, and 70° to 75° by day, admitting a little air at 65°, increasing with the temperature, closing at 75°. Attend to disbudding and tying-in the shoots, being careful not to overcrowd them, thinning the fruit, syringing the trees morning and afternoon to keep red spider in check, except when the trees are in flower. Distribute the pollen with a camel-hair brush unless bees are active, when they will do it much better than can be effected by any brush or shaking of the trees. Do not allow the border to lack moisture,

as this is a sure means of having plenty of red spider. Fumigate upon the first appearance of aphid.

Cucumbers.—Maintain a brisk growing temperature, syringing twice a day, keeping the evaporation troughs filled with liquid manure, being liberal also in the application of liquid manure to the roots of plants in bearing. Attend to stopping, thinning the shoots, &c., frequently. Plants some time in bearing may have the bed renovated by removing with a small fork any exhausted soil without injuring the roots, replacing with rich fresh soil previously warmed. Young plants require attention by timely training over the trellis, avoiding overcrowding of the foliage. A little fresh soil should be added to the sides of the ridge as the roots show, repeating the practice until the root space is filled with soil. Cucumbers in frames should have the linings frequently attended to, having always at hand prepared fermenting material for that purpose and for the making of fresh beds as required.

Melons.—The earliest plants will be showing fruit. The atmosphere should be kept rather drier. Impregnate the flowers in the early part of fine days, stopping the shoots one joint beyond the fruit, being particular to have all the blossoms upon a plant operated upon at the same time, so that they may set and swell together. Soil must be added to the sides of the ridge or hillocks as the roots show at the sides both to plants in houses and in frames. We are careful to secure four shoots to each plant in frames, two being trained to the front, the others to the back, rubbing off all besides when quite young, stopping the principal shoots at 6 inches from the sides of the frame. The fruit shows upon the side shoots or laterals. A brisk bottom heat and rather dry atmosphere are essential to a good set. A little air left on at night prevents moisture condensing upon the blossom, which is injurious. Attend to the lining, making fresh beds, potting off young plants, and sowing seed for succession.

PLANT HOUSES.

Stove.—It is fatal to the flowering of Allamandas, Stephanotis, and other climbers trained to balloon or other trellises to keep the shoots closely trained down as they grow. The shoots of Stephanotis should be allowed to run up strings of small twine stretched near the glass until the trusses of bloom are nearly expanded, when the growths may be tied to the trellis; and Allamandas, Bougainvilleas should be allowed to grow until the bloom is set. Some cultivators make a practice of stopping Allamandas, but though it answers well for the moderate growers, such as *A. grandiflora* and those suited to growing in bush form, it is not suited to those making long shoots, it being better to tie-in the long shoots with their points slightly lower than their base. This will cause them to push fresh shoots freely, which will produce flowers. *Hoya imperialis* should, when it shows the flowers, be kept rather drier, the syringe being withheld, or the flowers will probably drop. Similar remarks apply to *Cyrtoceras reflexa* and *Hoya bella*. Poinsettias that have had a season of rest cut back rather closely, placing them in a growing atmosphere, and when they break shake out and repot them. The increased solar light and heat will cause greater evaporation; therefore maintain a good moisture by frequent sprinklings, syringing overhead twice daily, but syringe early in the afternoon, so as to have the foliage dry before nightfall. Keep a strict look-out for insects, which increase rapidly with the increased temperature. Insert more cuttings of *Euphorbia jacquiniiflora*, potting off those already struck; also *Gardenias*, *Allamanda*, *Tabernaemontana*, &c. Do not allow the roots to be matted before potting off, and on the other hand not potting off until well rooted.

Orchids.—Lengthened days render an increase of temperature necessary and increased moisture. The floors, &c., should be damped early in the morning, the pots, blocks, and baskets syringed, the evaporation troughs filled with water, damping the floors in the afternoon and in the evening of fine days. *Calanthe vestita* shake out of the old soil and cut away the dead roots. Three parts of peat, and one part of turfy loam and old cow dung, with a sprinkling of silver sand, will grow it well. When the plants commence growth water freely, never allowing them to become dry until the growth is complete. *Calanthe Veitchi* is one of the finest winter-flowering Orchids. *Dendrobiums* showing signs of growth and requiring fresh baskets or pots should be promptly attended to. *Pleiones* growing freely will require abundant water at the roots, but be careful in syringing overhead. *Sobralias* repot, and *Anguloas*. Gradually increase the moisture in all the houses now that many plants are pushing new growths and spikes. See that the shading is in good order, using it when the sun's rays are powerful, thereby maintaining a more equable moisture. The temperature in the cool house keep at 65° to 50°; Mexican house, 75° to 70° by day, 60° at night; Indian house, 70° by day, advancing 10° from sun heat, 65° at night.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

SNOWFLAKE POTATO (*Northumbrian*).—We cannot tell you how long the tubers continue in good condition for the table, but we had some early in February of excellent quality. We esteem this variety as being among the best of the American introductions.

MAKING AND PLANTING ASPARAGUS BEDS (*Homer*).—Full directions are given in another column by "A Kitchen Gardener."

GRUBS (*Rosecareen*).—They are the larva of the Daddy-longlegs (*Tipula*), and come from eggs deposited in the soil by the parent insect.

CLEMATIS FOR A WALL (*P. C.*).—Clematis would thrive admirably on a wall facing west, where the sun would reach them about noon every day. Roses, Jasmines, and Honeysuckles would also succeed in the same position.

FIG TREE UNPRODUCTIVE (*Subscriber*).—Your plan of grafting the large unfruitful Fig tree is quite practicable, the best time being in spring as soon as the swelling buds indicate that the sap is in motion, but the scions should be cut off and thrust into the ground before the buds swell. Do not shorten the branches overmuch, but leave plenty of them of such a length that the growth resulting from grafting may be turned to immediate account for the production of fruit. We have no particular method of grafting to recommend; tongue, cleft, or side grafting are equally good for such a free-growing tree as the Fig. We must caution you that there will be considerable risk of the growth of the new kind, whether it be Brown Turkey or any other, soon becoming rampant and comparatively barren unless root-pruning is practised; and we have no doubt your tree might be made to yield fruit plentifully without grafting if you sever all the main roots about 5 feet from the stem, and ram hard a mass of stones or concrete about them so as to confine them, and thus check the formation of gross barren shoots. If the branches are much crowded a moderate thinning is desirable to afford space for the play of light and air among them.

CUTTING-DOWN CAMELLIAS (*P. H., Kendal*).—Provided the plants are in a healthy state and have active roots you may prune their branches to any point desired—we mean, you may cut them as severely as Geraniums are often cut if you wish to do so. If after having been severely pruned the plants are placed in brisk moist heat and are syringed regularly they will push fresh growths from the old wood, even when no buds were visible. Many "leggy" and unsightly Camellias have been converted into close handsome specimens by cutting them down in the manner described; they, however, do not usually flower freely the year following. If you do not require to prune so severely, shorten the branches to the most promising wood buds and place the plants in a moist genial atmosphere, and repeat them when they have made shoots about an inch long. This operation must be performed carefully, as the young flesh roots are extremely liable to receive injury. Remove any sour soil from the roots with a pointed stick, and repot in a compost composed of two parts of light turfy loam, one part of turfy peat, and a sixth part of silver sand. The pots must be clean and be thoroughly drained, a layer of rough clean fibre being placed over the crocks to prevent the soil washing down and choking the drainage. Use the soil moderately moist but not "pasty," and press it in the pots rather firmly, leaving sufficient space at the surface to hold enough water to percolate through the entire mass of soil. The pots should only be just large enough to admit the roots without crushing them, as overpotting is dangerous. Water carefully. Keep the foliage scrupulously clean, and the plants will make rapid growth in a suitable temperature, such as that of a vinery or plant stove.

LAPAGERIA SICKLY (*G. M.*).—We are disposed to attribute the sickly condition of your Lapageria to careless potting, the drainage probably being defective. Turn it out of the pot, shake most of the soil from the roots and repot in a clean small pot, paying especial care to secure efficient drainage. Syringe daily, but avoid much watering till the plant is growing freely, then give regular and copious supplies of water.

WHITE BEDDING PLANTS (*A Subscriber*).—There is yet time to raise a stock of plants by seed of Lobelia The Bride, Clarkia Tom Thumb alba, Viola Vestale, and Ageratum Imperial Dwarf White. Buy cuttings of Cineraria corymbifolia, Centaurea ragusina compacta, Leucophyton Brownii, and Gnaphalium lanatum, and strike them in a heated frame.

CAMELLIA SHEDDING ITS LEAVES (*A Staffordshire Reader*).—The air of the house is probably kept too dry.

WATSONIA CULTURE (*J. C. Barnham*).—When grown in pots they require to be potted three bulbs in a 6 or 7-inch, or five bulbs in a 7 or 8-inch pot, and should be plunged in ashes in a cold pit or frame, or be placed upon a cool moist bottom, withholding water until growth commences, when it should be given moderately at first, increasing the supply with the growth, affording a light and airy situation. No more forcing should be given than that of a pit or cool greenhouse until the plants show for flower, when they

may be forwarded in a slightly higher temperature. Your non-success is to be attributed to the plants being kept in too high a temperature at starting. A vinery is not a suitable place to grow them in, unless it is a cool one and light.

HEATING GREENHOUSE (*J. B.*).—Your proposed method of heating is not satisfactory, as the pipes are all below the boiler you propose to fix to the kitchen range, and as you show in your sketch would not heat more than the water in the boiler, owing to the water not circulating. Any part of the boiler lower than the fire grate will lessen the heating power of the boiler. We should have an "Independent Slow Combustion Boiler" either in the greenhouse itself if you have no outhouse to set it up in, being less costly and very much more satisfactory in result than heating from the kitchen fire. Why not have the boiler in the scullery? The boiler would warm it as well as heat the greenhouse.

FLOWER BED ARRANGEMENT (*An Amateur*).—Oxalis corniculata rubra comes readily from seed, has foliage of a warm brown hue, and makes a pretty dwarf compact mass or a good "ribbon" row. The plant of dwarf compact globular outline is Lobelia pumila grandiflora; another of the same peculiar habit and having rosy lilac flowers is L. pumila Manve Queen. The arrangement of border 1 is excellent, but in No. 2 we should prefer Cerastium next the grass, then the Oxalis, between which and the pink Geranium the pale blue Ageratum Imperial Dwarf should come. It is easily raised from seed. For a damp shaded border like No. 3 we should not venture upon blossom, but depend entirely upon fine-foliated plants; not in this instance, we regret to say, to be raised from seed, but as the border is narrow it may not prove an insuperable obstacle. The row next the grass to be Iresine Herbstedii, deep crimson; next a broad row of the soft grey Gnaphalium lanatum, with a mass of the Iresine behind in the deep central part. The Iresine bears pinching and pegging well, so that the front row can be kept as low as you please. For No. 4 we do not advise an attempt at carpet bedding from seedlings, but should prefer to have the entire bed filled with double Portulaca, consisting either of the crimson Thellusonii or of mixed colours, all of which come freely from seed. They like a dry position and much sun. We congratulate you upon the elegant outline of your beds. Such gracefully flowing curves are infinitely preferable to a formal geometrical pattern.

ROSE BOXES (*Ploughboy*).—Your letter shall have our attention.

APPLICATION OF SEWAGE TO GROWING CROPS (*De Bosco*).—You are decidedly in error in thinking the application of diluted sewage once a month last summer to your Roses caused the leaves to turn yellow and drop off, for, on the contrary, this premature decay of the foliage is a sure indication of exhaustion from drought. See that your Rose beds are well drained, loosen the surface soil occasionally, and pour on your sewage as soon as the spring growth is pushing freely; pour it on undiluted just as it comes from the pump once a week in spring and twice a week in summer, and do not indulge in mere dribbles, but give it with a lavish hand. We have just such a cesspool and pump as you describe, and in summer it is almost in daily use. Roses, fruit trees, Grape Vines, Strawberries, Raspberries, flowers, vegetables—all have as much of it as we can find time and labour for the work; we have an ample supply, and pay very little attention to given quantities, but may state that we have given six gallons daily to a single Cucumber plant in very hot weather, and the growth, foliage, and fruit was extraordinary. A lesser quantity, however, will suffice to promote healthy growth and the production of a crop of fruit of average excellence.

ARTIFICIAL MANURE FOR MANGOLDS (*S. S.*).—We have obtained excellent results by using Lawes' grass manure at the rate of 6 cwt. per acre, sown with the seed. We are told that Amies' chemical manure applied in the same manner and at about the same rate is equally good. Notes on the cultivation of Mangolds will in due time appear in the "Home Farm" department of the Journal.

FERMENTING MATERIAL ON VINE BORDERS (*Idem*).—We are not in favour of using fermenting material to generate heat on Vine borders, and when intending forcing early Vines rooted into borders outside the vinery, we prefer covering the border with a couple of feet of dry litter by the end of September, placing shutters or other covering upon the litter to throw off rain, thus keeping the roots tolerably warm by shutting in some portion of summer heat and excluding cold rains and frost, and so we are able to venture to animate the growth by artificial heat sufficiently early to obtain ripe Grapes in May.

ARTIFICIAL MANURES (*A Lover of Rose Shows*).—The London Manure Company, 66, Cannon Street, London, E.C., supply them.

WORMS IN LAWN (*S. Garner*).—Put quicklime fresh from the kiln into water—a gallon of lime to twenty gallons of water—and when the water is clear pour it over the turf and the worms will come to the surface. We know of no work on lawns.

ANTS (*A Subscriber*).—Sprinkle Scotch snuff over their runs until they abandon them. The Fern may be syringed.

INSECTS IN VINERY (*A. A. M.*).—Sulphur applications will not do harm if the paint is not placed in contact with the buds of the Vines; neither will fumigating injure the Vines when they are swelling their buds. It is, however, always preferable to fumigate moderately for two or three consecutive nights rather than to give one very strong smoking. You do not say what insects you are troubled with, so that we are unable to give you more explicit advice.

NAMES OF FRUITS (*S.*)—Pine Golden Pippin.

NAMES OF PLANTS (*A. M.*).—1, Salvia Heerii; 2, Salvia splendens; 3, Eupatorium gracile. (*A. E. U.*).—The Ferns are all forms of Polystichum angulare; 5 is an Eriostemon. (*H. E.*).—1, Nephrودیум Filix-mas var.; 2, Polystichum angulare. (*J. L.*).—Your gardener is right. (*E. L.*).—1, Sedum sp.; 2, Pyrethrum frutescens. (*J. Everard*).—It may be the Acaia you name, but we cannot be sure from specimen sent. (*W. P. P.*).—Your Orchids had withered before they could be examined, and the other specimens were mere fragments of leaves. (*E. Thomas*).—1, Nephrودیум exaltatum; 2, Asplenium flaccidum; 3, Indeterminable. (*R. F. L.*).—1, 2, Nephrودیум Filix-mas; 3, N. spinulosum; 4, Nephrودیум cordifolia. (*E. L.*).—3, Codium variegatum; 4, Selaginella cuspidata; 5, Nephrودیум molle; 6, Pelica hastata. (*Mrs. L.*).—All four are forms of Asplenium Adiantum nigrum. (*A. B. C.*).—The larger flower is Narcissus Jonquilla, the smaller N. Pseudo-Narcissus var. minimus. (*A. T.*).—We cannot identify from leaves only. (*Constant Reader*).—The unnumbered Ferns are Nephrودیум molle corymbiferum; Polypodium vulgare var. caubricum; Gleichenia, species indeterminable. The Orchid is Dendrobium nobile. (*A. H. S.*).—Odontoglossum Pescatorei.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTURE OF CLOVERS AND GRASSES.

BROAD or red clover is the leading sort and most coveted by farmers generally. It is, however, the most difficult of all the varieties to cultivate, and is so uncertain that it is often stated no man can say when he sows it whether he will secure a regular plant or not, and particularly where the land varies much. There are several varieties met with in the market, the old-fashioned English sort being the best of all. Much seed is offered derived from abroad, particularly from Normandy, and some from North Germany. The latter is more like the old English in sample, being a large flat-shaped seed. The sort from the south of France has smaller seeds and rounder, besides which the habit of growth of this French variety differs, and does not produce such heavy crops; nor is the second crop so certain as our old English sort, and it is somewhat difficult for a novice to discover the difference between our home-grown seed and that of foreign growth. It has been the practice now for some years to sow the French seed and save from it. Much of the bulk offered as English growth is still the foreign variety, and has not really the value of our old English variety, which is of a deeper purple colour than foreign seed. It is therefore best, when it can be seen growing, to obtain seed from a crop which has the characteristic of old red clover—namely, a large leaf and gross habit of growth.

It is usual to sow broad clover with the Lent corn, and as both barley and oats are sown on recently-tilled land it is often more or less hollow and wanting in firmness, and particularly where roots have been fed off by sheep the land is often cloddy, and very much against the taking of the clover plant. We often see that the headlands show a good plant of seeds and the remainder of the field very irregular, and it is fair to infer that the firmness and fineness of the land produced by the extra treading of the horses and turning of the harrows, roller, &c., is favourable for the young clover plant. Another illustration of the requirements of this plant is the almost surety of obtaining a regular plant when sown in the spring in an autumn-sown wheat crop. The land is then firm, and we have always secured a regular plant except on some occasions when partially eaten by the small white slugs, which are its greatest enemy. We recollect having obtained a fine plant seeded with wheat, after potatoes and turnips, five years in succession, and on each occasion the clover was cut up for horses and cattle during the months of September and October. Nor did this autumn cutting at all injure the produce in the following year, but, on the contrary, it was better after mowing than when fed by sheep or cattle in the usual way in the autumn. In sowing the seed, however, with the wheat, the land being hard on the surface, it should be harrowed with the iron harrows before sowing the seed, then roll with the ring roller, sow the clover seed, harrow with the chain harrow twice over, then leave it rolled. In this way the hard shell of the land is broken very fine, and the seed being sown after the ring roller cannot be buried too deep, nor can any seed be left uncovered, the land being entirely stirred by the chain harrow. When the clover seed is sown with Lent corn we recommend that it should be simultaneously with the barley or oats, and be rolled immediately afterwards with the ring roller.

There is a very general opinion existing that the surest way to obtain a good plant of clover is to vary the sort, and instead of sowing red clover once in every four years to sow it at the end of eight years, taking a crop of another sort of clover or grass in the intermediate course. The advocates of this plan say the land becomes clover sick; but we hold to the opinion that it is the proper tillage and firmness of the land, and its being in good heart and condition which secures the plant, for we know

certain light and gravelly soils where red clover has been sown mixed with the other grasses on the four-course rotation for a period of forty years and has never failed, but the land was well tilled and worked extremely fine before sowing the seeds. Red clover always flourishes most on loamy soils of any kind, still one of the great essentials is that the land should be fresh in chalk or lime; and if it is true that land can be clover sick it may best be cured by the application of gypsum and bone superphosphate. One of the greatest advantages of red clover is that when a good crop is obtained there is always a large quantity of strong roots, which ploughed in and pressed constitute one of the best preparations for the wheat crop on loamy and dry soils. The weight of roots per cent. is great, and in course of decay supplies the wheat plant with a large amount of the most valuable manure.

Alsike Clover.—This variety came originally from Sweden, and is no doubt a hybrid between the white Dutch and broad clover. It is perennial in its nature, and is productive. When it first came out as a new sort it was thought valuable as a change when broad clover failed, and has often been sown either with it or as a substitute for it. It is found, however, that the second growth after being mown for hay is very deficient, and consequently the Alsike clover has not extended in cultivation for some years. There is only one other point to be named, and that is in its favour, for we find when sown with broad clover, and that a part of the crop is required to stand until late with the view of cutting up for cattle or horses before the second crop is ready, that the Alsike continues to grow and bloom somewhat like the late varieties of peas, and continues of good feeding value for a lengthened period. The seed of Alsike is of a very dark green colour, and is more adapted for mixture with permanent grasses for pasture than for alternate husbandry under the four-course rotation of cropping.

White or Dutch Clover.—There are two sorts. The permanent and creeping variety is adapted principally for pastures. The other is called the long-haulmed, and certainly on favourable soils and situations yields a heavy crop. We recollect on certain occasions of cutting before it came into bloom for the especial purpose of making into hay for our early lambs, and we cannot grow any sort of hay so valuable for that purpose. The herbage is so fine and soft that when the Dutch clover is sown alone without admixture with rye grass the lambs eat it at an earlier age than any other sort of hay, and when the weather has been favourable and the grass cut early we have had the sample almost resemble a sample of hops both in colour and fineness of leaf, and on those occasions we have had quite 1½ ton per acre; and our lambs fed upon it with roots without cake or corn have been of the best quality, not only as regards fatness but most esteemed by the consumers.

(To be continued.) ~

WORK ON THE HOME FARM.

As vegetation is beginning to be somewhat active it will be necessary for husbandmen to be active likewise. The various operations of the farm in which the horses will now take part are of the most important nature. Where the land has been previously ploughed and intended for barley it must now be cross-ploughed if a fine tilth is not to be obtained without it by scarifying, and this will engage the horses for a short time. The horses, however, should be engaged in drilling beans and peas if not already done, as this is the latest time they can be sown with the best prospect of a crop, for when sown later than the middle of March they are more apt to suffer from blight. The best bean for sowing at the late period is the early *Mazagan*. It is the largest bean in sample of any sort used in field culture, and is also the best variety to grow for a double crop—that is, in admixture with vetches or small maple peas, as the corn is more easily separated if required. The advantage of this double crop is great, for we seldom or never find both crops suffer from the aphid which so often ruins the crop. The black aphid which injures the beans is brought by the east wind, the green aphid which attacks the peas is found when the west wind prevails, and it is seldom that these two kinds of insects prevail in the same season. In this double culture we drill two bushels of beans and half a bushel of peas or vetches per acres. As soon as the land is horse-hoed and hand-hoed the peas or vetches fill up the space between the rows of beans and effectually keep the weeds down. The meadow land and clover seeds must also be rolled if not already

done, because after the drying winds peculiar to the month of March the land becomes hard and will not yield to the pressure of the roller except in some moist meadow land. In drilling all the Lent corn, both barley and oats, let the rows be 12 inches apart; the plants will then have a free circulation of air between the rows, and in consequence a more healthy and vigorous growth, with stouter and stronger straw, and less likely to fall down with wet and wind on the eve of harvest.

The shepherds will now have nearly obtained all the lambs they expect from the down ewes, but they will still require constant care and attention; and if the farmer or bailiff finds it difficult to obtain a good shepherd, as we have done, it is better to always have an under shepherd, who will the more readily learn the work required of him as compared with some old hands, who have ways of their own and will not be taught or obey.

The feeding of farm horses is of great consequence, as they have now much heavy work to do. When they are fed ever so liberally with all dry food they cannot sustain the work so well as when they get a fair allowance of root food, such as swedes, mangel, or carrots, the latter being the best, and it is the old-fashioned food used in the eastern counties, as described in a report to the Board of Trade in the year 1776, wherein it is stated that carrots were so largely used as to form half the allowance to farm horses—that is to say, one bushel of oats per week were displaced by five bushels of carrots; and in this way, if we take the produce of the land by comparison, one acre of carrots will go as far in horse-feeding as four acres of oats, not including straw. The horses will also be much forwarder in their coats, more healthy, less liable to broken wind, and certainly longer-lived when fed on roots, say about 20 or 22 lbs. daily, than when fed on oats and hay only during the winter months and until the early fodder crops are ready, such as green rye, Italian rye grass, and trifolium.

The feeding of pigs also with root food is a matter of economy in farm management. The breeding sows will eat almost anything; but young and growing pigs, as stores, will not do well upon the mangel. We have known pigs die off when so fed, and on *post mortem* examination the lungs have been found black like the appearance of pleura; but this is only found in young animals under six months old and when they have but little else besides mangel. If, however, a liberal quantity of meal is used, either of barley or bean meal, and mixed in a pulp with mangel it feeds them profitably, and is one of the best mixtures we have ever used. The quality of the meat also as pork or bacon has always been satisfactory.

The days are now long enough to commence any repairs that may be required to the farm buildings, gates, pales, &c., and such work may now be done with advantage. We often delay some repairs until the spring, because in the short days of winter the carpenters, bricklayers, and others cannot do a full day's work, which at the present high wages paid to such workmen and artisans is of great importance. The odd horse will now be useful in carting some of the materials required, such as tiles, slates, deals, and other timber, also drawing rough timber to the pit ready for the sawyers; it is, however, a common practice to employ steam power for sawing where any considerable extent of work is to be done.

ARTIFICIAL INCUBATION.

FROM time to time an ephemeral rage for artificial incubation sets in among us. We remember this being the case about thirteen years ago, our advertising columns contained many tempting descriptions of incubators. We tried two ourselves, but were too busy to make anything like scientific experiments of them. Many of our friends tried others, and almost all with the same unsatisfactory result. It was a subject for regret that these trials were made in a somewhat purposeless way and without sufficient perseverance. However, the poultry-fancying public soon got tired of the pastime, and we heard many an exclamation, "Well, there is nothing like old hens after all." Second-hand incubators were everywhere offered for sale, and artificial hatching died a natural death. We have taken much pains to discover whether in any considerable English establishment it has been successfully and continuously carried on for any time, but we have not as yet heard of any instance of it. Meanwhile ingenious people have not been idle, and several fresh incubators of very clever and some of very elaborate construction have been brought out. A prize offered for them last autumn at the Agricultural Hall gave a fresh stimulus to the interest in artificial hatching, and we hear from many quarters that it is being seriously tried this season, and with, we hope, prospect of much greater success than has been usual, at least in this country. That it has been practised in other ages and in other lands is a matter of historical fact. That which has been done may, unless some important conditions have been changed, be done again, and therefore it is of practical use to glance at its past history in hopes of discovering the reason of our present want of success. In an age, too, which boasts to have reached an unparalleled pitch of scientific knowledge, it is instructive and interesting to look back to times in which those

whom we are used to regard as barbarians, and who certainly lacked many scientific aids and instruments which we now possess, by dint of quiet perseverance through inductions made from many experiences fathomed certain natural laws of which we are ignorant. We shall, therefore, attempt to give a short history of the art of artificial incubation, derived, as far as it has been in our power to reach them, directly from original resources both ancient and modern.

Like much other wisdom the knowledge of this art seems to have travelled from the remote East. In those ages of a, to us, prehistoric civilisation, the Chinese and Indians hatched eggs by heat generated from decomposing organic matter. To this day the unchanging Chinese hatch Ducks' eggs in the same way. From India this method doubtless passed into Egypt, where the priests of Isis kept the secret to themselves. The Egyptians hatched countless chickens by placing the eggs in vessels which they plunged into hotbeds of dung. Subsequently this primitive method gave way to the celebrated ovens. Our authorities for this ancient artificial incubation in Egypt are Aristotle, Pliny, and Diodorus Siculus, but their accounts of the Egyptian system are not very definite. The famous French missionary traveller, the Père Sicard, is much more explicit, though himself quite conscious of the deficiency of his own knowledge, for he did not find artificial incubation commonly known among the Egyptians, but the secret and monopoly of one village, Berme in the Delta, handed down from father to son. (*Il s'apprenait à leurs enfans et le cachait aux étrangers.*) Towards the hatching season—i.e., early in autumn, these Bermeans dispersed over the country, and each one took a situation as manager of an oven, and they and they only were employed in its regulation. About the construction of the ovens there was no mystery; they were when not in use open to the public, and are to be seen to this day: the treatment of the eggs while in them was the only secret. Monconys, Thouvenot, and other travellers have also described the ovens. We will translate a summary of their descriptions from a work by M. Malézieu:—

"The incubator (in Arabic 'chicken machine') is a rectangular building divided in its entire length into two parts by a corridor, on either side of which are the hatching ovens. They are in two tiers, the lower ones 1 metre in height, 2 broad, and 3 long. Each is provided with a door opening into the corridor, and with a good-sized round hole communicating with the upper tier. The dimensions of the upper ones are the same, save that they are two-fifths higher. Each has five apertures—one on each side communicating with the next oven, one above in the middle of the arched roof opening to the external air, one door opening into the corridor, and lastly the round hole at the bottom communicating with the oven below. Near the oven house is the place where the hot fuel is prepared, consisting of a substance made of rough straw and the dung of camels, horses, and cows. Close to this again is a chamber destined for the reception of the newly-hatched chickens. An egg room and an apartment for the manager complete the apparatus of an Egyptian incubator. Let us go on to the details of the operation, and for clearness' sake we will designate the ovens on each side of the corridor respectively by the numbers 2, 4, 6, 8, 10, 12 and 1, 3, 5, 7, 9, 11. They begin by working Nos. 2, 4, 6, 8, 10 on one side and 1, 3, 5, 7, 9, 11 on the other, thus:—In the lower chambers of the said ovens they place the eggs on a bed of cut straw and earth, then into the upper chambers they carry red-hot fuel, which they place in a trench running entirely round the hole communicating with the chamber below. The fire is kept up to a proper heat for ten days, which is the first period of the operation. At the expiration of this time they let the fire out and carry the eggs from the lower to the upper stage. At the same time they set to work the alternate ovens, 4, 8, 12 and 3, 7, 11, which have hitherto been unused; in these, as in the others, they place the eggs below and the fire above. This is the second period of incubation; it also lasts ten days, at the expiration of which the chickens hatch from the first eggs, which have meanwhile been warmed by hot air from the lateral apertures communicating with the alternate heated ovens." [This, we may remark, explains to us the origin of the ludicrous mistake which Rollin makes in his "Ancient History," vol. i., page 52—viz., that the Egyptian ovens took ten days to heat, but that the eggs placed in them when duly heated hatched in ten days!]

"The newly-hatched chickens are taken from the oven, and after a while consigned to the people who rear them in a room of suitable temperature. The first lot of ovens being now free they begin with a fresh batch of eggs, treating them as the others; thus the whole operation lasts from twenty to twenty-two days, divided into two periods, and the incubator hatches a certain number of chickens every ten days. We may remark that this process of artificial incubation has the merit of being a careful copy of Nature. The reader will have already perceived that in it the eggs are never heated from below. During the first ten days they receive heat from the upper furnace—i.e., from above, as when under the hens and during the second half of the operation they are kept at a proper temperature by means of the hot air, which comes in at the sides from the neighbouring ovens where the fire is.

"We may call attention to the fact that the success of the

process depends upon the talent of those who regulate the heat, still these poor Egyptian peasants are ignorant of the fact that the necessary temperature for incubation is about 40° centigrade (104° Fah.). Even the thermometer is unknown to them; still so practised are they in their work that they keep up a temperature of from 35° to 40° in their ovens. That is somewhat below the temperature kept up in modern incubators; for instance, Cantelo's machine maintains from 40° to 42° (104° to over 107° Fah.). The chickens, too, in the Egyptian ovens hatch at the expiration of twenty to twenty-two days, but in Cantelo's incubator they often come into the world on the eighteenth or nineteenth day. On the other hand, the chickens hatched in the modern apparatus, like greenhouse plants, are of so delicate a constitution that they can hardly bear the external atmosphere.

"The Egyptian incubator, apparently so rude in make, is still well suited to its purpose. Almost buried in the earth it suffers little from variations of the external temperature. The poor fuel used in it is probably more suited to the maintenance of an uniform and moist temperature than a more costly one. The numerous apertures, too, of the fire chambers are of great use in the regulation of the heat, for when the manager finds it too great he can open the doors; on the other hand, when it is too low he can close all communication with the external air."—C.

(To be continued).

IMPROVEMENTS IN THE SMALLER VARIETIES OF RABBITS.

ADHERING to our previous division the following breeds will come under this head—the Silver-Cream, Dutch, Himalayan, Polish, and Siberian. Such a division is rendered necessary by the strange arrangements of the fancy. Thus if all were classed together, and the same general directions and suggestions given for the improvement of the breeds, we should get into some little difficulty. The same directions, which if carefully followed would make the Patagonian or Belgian Hare large and valuable, would completely spoil the Dutch; and the same suggestions that would tend to keep the little Dutch small and proper would make the Patagonian puny, weak, and valueless. With the varieties under notice improvements are easy, and these have been carefully seen to for several years: hence they are now in a much better condition than some of the larger varieties. More prizes, and often prizes of greater value, are offered for them, and they seem generally more cultivated, an exception being made perhaps in favour of the Silver-Grey. The rules as suggested for the larger varieties must be modified very much. It is quite impossible to dispense entirely with what is termed in-breeding when the size has to be kept down to a certain pitch or standard; but care should be taken to avoid the practice as much as possible, because the constitution and colour alike suffer. The breeds in which size is required to be kept down should not be overfed when in kindle, and larger litters may be allowed. The sires of every breed should be strong and free from any constitutional debility. In marking and form they should be as near perfection as can be obtained.

In the *Silver-Cream* Rabbit we may see the most perfect development of improvement. This breed has in two or three years grown into one of the most admired and sought after of all foreign varieties. The reason is that the general features are so very pretty and admired, and the value will increase with the popularity. Size in *Silver-Creams* is not as yet very definitely determined, but we do not like to see them very large. The best winners are between 6 and 8 lbs. in weight and rather long in the body. The parents should be selected about this weight, and both should be strong and healthy. Both should have the creamy shade, like a very delicate *Silver-Grey*. Several good *Silver-Creams* have been obtained by crossing *Silver-Greys* with yellow Dutch or hutch Rabbits, but the records of how the best strains were secured seem enveloped in mystery, and the owners refuse to disclose the secret. For actual improvement we suggest breeding in the variety itself as likely to improve the shade; but it is essential that the parents should not be related, as a departure from this rule will be found to cause a deterioration in the shade and will encourage blotches of white. With these precautions, and if pale does are paired with darker bucks or the reverse, it may be expected that the breed will continue to improve gradually.

The *Polish* variety is very weakly and delicate. The points to be preserved are a delicate white skin and fur and a good constitution. A good many are very weak and die young. It is difficult to secure perfect breeders; the parents should be large comparatively and strong. This Rabbit should not be confounded with the ordinary hutch Rabbit, with which it should not be crossed. The main difference will be found in the circumstance that the pure-bred Rabbit is long and thin, whereas the less valuable one is thick and heavily made. There is also a difference in the eye. The *Polish* eye is very light.

The *Dutch* is also susceptible of improvement. As far as colour goes the remarks on the Lops will apply equally. It is supposed to be right to keep Dutch Rabbits small. It is consequently the practice to cross very near relations to keep down the size. It is

a pity that the fancy has decided in favour of this pretty variety being kept small, because the efforts made to keep down the size also weaken the Rabbit in many ways. As size depends a good deal upon the amount of nourishment received when very young very large litters of this variety are raised.

Improvements are needed very much in the *Himalayan* Rabbits. They are easy to be effected, but the results are not always quite the same, and patience is sometimes rather sorely tried. Size should be uniform and moderate, so in-breeding must not be encouraged. The points to be looked to most are the darkness of the points and the quality of the fur. Now it often so happens that a Rabbit has black eyes and grey feet, while another is good in feet and poor in the ears. Such a pair crossed would probably produce a highly improved litter. If the nose is bad and the feet moderate a dark-nosed mate should be selected for it. The bucks should be as perfect as possible, and they should be healthy and strong. The fur of both parents should be clear white and very short. If there is any foul upon a Rabbit of this breed—or indeed of any other—such as a bad mark on the dark portion of the fur, or a dark mark on the white, discard it at once for breeding.

The *Siberian* is an improvement. If the selected doe is good in wool, long and shaggy, and at the same time soft and flexy, but her dark points are light or grey, the buck should be very dark in his ears, nose, and feet, and if a little deficient in wool it will not much matter. In fact it is perhaps as well to select breeders that are extra good in one respect and a little weak in others rather than those that are about average in every respect. By that means any faults are the more easily eradicated. Carefully pair them so that no similar faults appear in both, or they will be greatly aggravated in the offspring.—GRTA.

THE LATE MR. C. W. JOHNSON, F.R.S.

IN addition to our remarks on the death of Mr. C. W. Johnson in last week's number (page 215) we extract the following from *The Croydon Guardian*—"The circumstance that first brought him into notice and into usefulness in Croydon was his taking the lead with a few other gentlemen in advocating the passing of the Public Health Act, and, as soon as it had passed, establishing a Local Board of Health in Croydon—one of the first local boards after the passing of the Act.

"He had, for some time before this, experimented and written on the great and difficult subject of the disposal of the sewage of towns. He was one of the first that pointed to irrigation as the best mode of thus turning evil into good, and his views gradually gained ground until they were sanctioned as scientifically correct by the report of a Government Commission.

"Twenty-nine years ago the Croydon Local Board was appointed with Mr. Johnson as the Chairman, and with only a small interval he has laboured at that post till his retirement in 1877. He published an edition of the Public Health Act with notes, which was widely used by the Government offices and by local boards and the public; and he therein pointed out by his notes that local boards had duties to perform for which sufficient legal powers were wanting. He struggled on, however, and aided the Board in the many difficulties which, in the then state of the law, they had to encounter and surmount, never sparing time or attention, and giving the ever-ready, valuable, and gratuitous assistance of a barrister to the difficult duties of the Board. In particular, he spared no time, attention, or exertion in aiding the Board of Health to fight the great water case against the Wandle mill-owners. When £30,000 of ratepayers' money had been spent on the Croydon waterworks and mains, a decision in the Exchequer made them suddenly useless. They could not be worked without diminishing the water in the river Wandle, and this was decided to be unlawful. The Board, however, traversed this decision, and although the mill-owners appealed to the Lords Justices, and being beaten there appealed to the House of Lords, yet the Board continued the struggle before that tribunal, and gained there a complete victory, establishing for ever their present right to pump any quantity of water that their wells can yield, whatever effect this may have on the water in the mill stream.

"The funeral of the deceased gentleman took place on Wednesday afternoon in the burial ground of St. Peter's Church. The deceased was followed to the grave by a number of friends and relatives, the chief mourners being Mr. G. W. Johnson, co-editor of the *Journal of Horticulture*, Mr. C. N. H. Johnson, nephew, and Miss Gower, niece of the deceased. Dr. Hogg, co-editor of the above Journal, and some private friends of the deceased were also present, including W. Drummond, Esq. (the present Chairman of the Croydon Local Board of Health), and Mr. R. J. Cheeswright, Clerk to the Board. The funeral service was impressively performed by the Rev. Canon Hodgson, Vicar, assisted by the Rev. J. White, incumbent of St. Peter's, and the remains of the deceased gentleman were consigned to the tomb in which his wife was buried several years ago."

Croydon Advertiser, March 16th, 1878.

"WHEN next the Board of Health assembles it will have to pay a

tribute of respect to an honoured memory, for Mr. Cuthbert William Johnson has passed away. The event was not altogether unexpected, but none the less will it inspire regret. Mr. Johnson was a type of the fine old English gentleman who is now becoming rare. During the many years that he officiated as Chairman of the Board of Health, although his temper was often sorely tried, he exhibited a happy mixture of tact, firmness, and courtesy, which was never departed from under any circumstances. Combining the *suaviter in modo* with the *fortiter in re*, he managed to control the most unruly spirits, and if the Board of Health could ever fairly lay claim to be a dignified assembly, it was certainly while he held the reins of office. A lawyer of no mean ability, his sound legal knowledge was often of great service to the Board when difficult or delicate matters had to be adjusted. Of genial disposition, he occasionally enhanced the dull routine of business with some little joke that met with general appreciation; but with his witticisms there never mingled any of the bitterness of satire, nor were they calculated to wound in the slightest degree the personal susceptibilities of any individual. In brief his chief characteristics were

High nature, amorous of the good,
But tinged with no ascetic gloom.

The domains of Science, Art, and Nature had each and all for him special attractions. He was the pioneer who led Croydon along the path of sanitary progress—the champion of that system of irrigation by which the dead refuse of the animal creation is made to minister to the wants of vegetable life. His ideas on this head were at first received with some degree of scepticism, but now there are many converts to the system he advocated, and the practical outcome of which is to be seen in the Board of Health's farm at Beddington. In the pursuit of his tastes he divided his affections pretty equally between the useful and the beautiful. If he was an authority on irrigation, he was no less a lover of arboriculture. It was under his direction that the Croydon cemetery was planted with shrubs, so admirably selected and arranged that bloom or foliage is always to be seen in that place of solemn memories. He it was, too, who dissipated the erroneous idea formerly entertained that trees in proximity to dwellings were unwholesome, and therefore undesirable. It was chiefly at his suggestion that in the Brighton Road, at Duppas Hill, and various other parts of Croydon, avenues were planted, which it may be hoped will attain stately growth and cast a grateful shade over spots which were before singularly arid and shelterless. These tangible evidences of taste and judgment will continue to exist as so many monuments of the good man who has passed away, and some of them, it is to be hoped, will preserve his name as one worthy of the reverence of posterity. Certain it is that by the death of Mr. Cuthbert William Johnson Croydon has sustained a loss which will be felt by many as a personal one. A man whose life has been consecrated to the true and noble, and whose deeds speak more eloquently for him than the most glowing panegyric that could be penned in words, will always have mourners in the wide circle that he adorned, and there are many who are connected by no ties of relationship with the deceased gentleman who will nevertheless claim the privilege of placing a chaplet on his tomb."

VARIETIES.

A CORRESPONDENT suggests that all growers of Prickly Comfrey should have a liquid manure tank on their premises, and as soon as the plants start to water round them plentifully with diluted liquid manure, taking care not to wet the leaves. This should be continually done.

THE quantity of food brought to Liverpool last week from America was quite up to the average of recent periods. Five steamers reached the Mersey, bringing collectively 5712 quarters of beef, 1628 carcasses of mutton, and 283 carcasses of pigs, whilst another steamer from Canada landed 150 head of cattle and 423 live sheep. No consignments of fresh butter came to hand.

THE imports of potatoes into London last week comprised 106,704 bags from Hamburg, 11,497 Antwerp, 13,522 Stettin, 8202 Bremen, 2674 Ghent, 746 sacks 61 tons Dunkirk, 771 sacks Rouen, 892 Harlingen, 200 sacks 150 bags Boulogne, and 241 packages Malta. The prices in the Borough and Spitalfields markets on March 18th were for Kent Regents, 190s. to 200s.; Victorias, 180s. to 210s.; Champions, 120s. to 150s.; Essex Regents, 170s. to 490s.; Rocks, 100s. to 130s.; Flukes, 190s. to 220s. per ton.

IN an admirable paper on the milk supply lately read at the Botley Farmers' Club, Mr. Joseph Blundell quoted the following old lines describing what a dairy cow ought to be, and he remarked that although they were written many years ago they apply equally well at the present time—

"She is light in her neck and small in her tail,
She's wide in her breast and good at the pail,
She's fine in her bone and silky of skin,
She's a grazer's without and a butcher's within."

THE *Rural New Yorker* publishes the following testimony of the value of Spangled Hamburg fowls:—Two years ago we purchased some eggs of the Spangled Hamburg variety, and we

are so well pleased with these fowls that we keep them only, having disposed of our old stock—Buff Cochins and Leghorns. The eggs of our favourites are small, as are also their bodies, yet they are the greatest layers we ever had and the easiest keepers. Our fowls eat but very little, and seem to lay summer and winter with little intermission, scarcely ever wishing to sit. Last summer we were obliged to obtain hens of another breed to sit. Their dark legs are a slight objection, yet their good qualities overbalance all their little defects.

THE Hull Cattle Plague Committee and Dock Company are preparing for the new conditions likely to be imposed on the landing and disposal of foreign cattle. The Dock Company have declared their readiness to provide for the slaughter of cattle in sheds on the south side of the Albert Dock, provided that the Privy Council will sanction the plan.

A VALUABLE herd of Highland cattle belonging to the Earl of Lovelace were entirely destroyed last week in his park at East Horsley in consequence of their having eaten the cuttings of a large number of yew trees.

IN 1867, 2152 horses, asses, and mules were consumed in Paris. In 1877, 10,008 horses, 558 asses, and 53 mules, furnishing 1,932,490 kilogrammes of meat, exclusive of the heart, liver, tongue, &c., which are also eaten; and there are now sixty-one horse butcheries. One will shortly be opened in London. Even if Englishmen are too fastidious, it is thought there are plenty of foreigners in London to serve as customers for the horse flesh.

AT a recent meeting of the Entomological Society Sir John Lubbock read a paper on the colouring of British caterpillars. Accepting the principle laid down by Mr. Darwin and others that dull-coloured, green, and smooth-skinned caterpillars are eaten by birds, &c., whilst spiny, hairy, and brightly-coloured species are rejected, the author stated that by the statistical method it was shown that no hairy caterpillars are green, whilst, on the other hand, a large majority of black and brightly-coloured species are hairy or otherwise protected.

AN American writer on poultry, Mr. Henry Hales, observes that unless you want a large proportion of cockerels do not set all the largest eggs you can pick out. There are no means known by which the sex of eggs can with certainty be determined. Although many have thought some signs indicated the sex, yet after repeated fair trials all these indications have entirely failed with me, except the one which follows:—With regard to the eggs of most of the feathered kingdom, if you pick the biggest out of a nest they generally produce males, especially if they happen to be the first laid. Even in a canary's nest it is noticeable that the first egg laid is very often the largest; the young from it is the first hatched out, keeps ahead of its comrades, is the first to quit the nest, and the first to sing.

MR. HENRY M. E. CROFTON communicates the following note on experiments with potatoes to the *Irish Farmers' Gazette*:—Last spring he planted 1 stone of each of the following kinds, supplied by Messrs. Sutton & Sons of Reading, in drills on the same day, beside each other in the same field, and with the same treatment, with the following results:—Suttons' Magnum Bónum produced 21; Paterson's Victoria, 12½; Late Rose, 4; White Rock, 7; Snowflake, 13; Griffé Castle, 5; Fox's Seedling, 5; and Early Hammersmith, 4 stones.

OWING to the great increase of wood pigeons, and their destruction to the crops of the district, a circular letter has, it is stated, been addressed by the officials of an old Fifehire association to the landed proprietors of that county, requesting that instructions may be given to gamekeepers and others to seize as many wood pigeons' nests and destroy as many young pigeons as possible during the ensuing breeding season.

A USEFUL invention has recently been made by Herr Weber of Hummel-Radeck, near Lübben (Prussia). This gentleman has contrived to construct a very simple machine for levelling roads, which for working requires only two horses, a driver, and a labourer, and renders it possible to make such improvements in a road in a short time as could otherwise be accomplished only by fifty or sixty workmen. The machine works equally well upon gravel or clay soil, and its cost is only forty-five marks (shillings). The whole machine works much in the same way as an ordinary carpenter's plane does upon wood.—(*Nature*).

ITALIAN VERSUS BRITISH BEES.

A STATEMENT published in the *Banffshire Journal* shows that the question has been taken up heartily by our friends in the north, and I hope they will make arrangements for a fair trial of strength this next summer. Mr. Campbell's challenge if accepted would not settle the question at all, for one swarm might be earlier, larger, or on better pasture than the other. In competitions of this kind the swarms should be of equal size or weight, stand together and commence work at the same time. These Aberdeen gentlemen are thoroughly honest and well-meaning, and besides are clever bee-keepers. We therefore expect that the conditions of trial will be well arranged and satisfactory to all

parties. Whatever be the result no one will lose anything, and therefore has nothing to fear.—A. PETTIGREW.

A SPRING OVERHAUL.

HAVING already endeavoured to show that bees are endowed with powers sufficient to withstand with impunity the most severe winters, always provided their domiciles be kept externally as well as internally dry, the openness and extreme humidity of the by-past winter, with its occasional sharp frost checks, caused the thoughtful apiarian much more anxiety for the well-being of his little favourites than one with long spells of clear dry cold frosty weather and free flights during the thaws. In our district, having had many reports of the sadly decimated numbers of stocks in the cottagers' apiaries, it was not without some misgivings on the forenoon of Thursday, the 23rd of February, thermometer 53° in the shade, that I summoned my assistant to fetch the operating table and the tools so that we might know the worst.

I had better first explain that after autumnal unions my stock numbered ten colonies all told, amongst which I had divided 1 cwt. best Greenock crushed sugar boiled up into syrup, besides giving three weighty unsealed-out supers placed below to be carried up for winter store. As usual the lion's share fell to the weaklings—swarms and swarmed stocks; but so wretched was the honey season of 1877 that (rare occurrence) my strong non-swarmling colonies even deigned to partake.

After careful tests, extending over several seasons, of the comparative value of the Italian and its first crosses I was led many years ago to discard the black bee, consequently these ten stocks had at their head respectively the Italian element as follows:—Three imported queens of last season to propagate from, three first-cross daughters of 1876 from such imported mothers, and four of 1877, these last taking the place in the fall of old and deposed sovereigns. Disliking the appearance of the end combs, and a slight dampness in the corners of a couple of square frame hives employed over the season to carry a greater number of sectional supers, I transferred, as is my wont, the bees and central frames to octagon Stewarton dry boxes for their better wintering. Of these ten stocks nine were then in Stewarton, the remaining in a straw hive, eked to prevent swarming. On finding the last of the late brood hatched out I stripped off all carpets and remaining super coverings, and placed the stocks in winter quarters, seven being under protection of substantial moveable wooden covers, and the remaining three under fresh thick straw hackles. Side entrances had been run in at the close of the honey harvest, and finding no appearance of propolis barricades being built at the entrance I concluded an open winter was to follow, consequently I left the central slide fully drawn for the better circulation of pure air; thus my ten stocks were left to take care of themselves untouched for fully four months.

To return to the 23rd of February. I commenced work with No. 3, common straw skep, under protection of the best wooden cover; and on raising the hive I was much mortified to find it quite dead, not, however, from starvation, as it was still weighty with surplus store, nor yet from lack of population. In addition to its own bees it had those of a large swarm safely added, and so far as I could see up amongst the combs not the slightest trace of foul brood. The combs being white and mouldy, I have no doubt the bees fell victims to dampness imbibed before the stock came into my possession, straw as a material being too ready to absorb and retain moisture when neglected in such a wet season as the last; fortunately the old adage held good—"A bad beginning makes a good ending," for all my nine Stewarton colonies turned out thoroughly dry and in excellent condition, fully provisioned to stand over a couple of months. The *modus operandi* of examination was as follows:—A stock was raised from its stand as gently as possible and set upon the table, all comb fillings and debris were rapidly scraped off with knives; the board, formed of old dining-table tops was then polished with a coarse cloth, the stock was replaced, slides drawn, frame after frame and comb by comb lifted out and carefully scrutinised, an audience sought with the respective sovereigns, the extent of eggs and brood in each hive estimated, and the surplus store duly appraised. Although my liking is towards the more sombre and larger first-cross bee, yet truth causes me to confess that the imported queens at the head of the weakest stocks were much in advance of others for breadth of sealed brood, showing in every case the pure Italian to be the earlier breeder.

I would here pause to remark on the oft-repeated assertion by disparagers of the Italian—that their superiority can be accounted for by such imported queens being usually placed at the head of the very best stocks in the apiary, when in actual practice the very reverse holds good; for this reason—the bee-keeper is naturally averse to dethrone the proved best breeders of his most populous stocks, both for their own sakes as well as from the greater difficulty in securing them amongst their crowds of offspring, hence such queens are too often placed at the head of the very weakest, and their breeding qualities are displayed to the best advantage in making up the leeway.

Your correspondent Mr. Pettigrew recently administered sound

advice to his brother fixists as to the benefit derived from uniting their weakest hives in spring, while we movists would shudder at the bare thought of destroying our valuable queens at this season while just expanding into the most matronly proportions. How simple the transference to such weak hives of a frame of ripe brood from a strong stock as required! We thus retain the breeding power of all our queens and apiary at its full strength.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

OXFORD SHOW (*J. Aldridge*).—You must state your case to an attorney, and he will advise you how to proceed.

COCK AND PULLET (*St. Honore*).—We cannot identify fowls from descriptions.

CROOKED COMBS OVERLOADED (*A. K.*).—Sometimes bees disregard guide combs and build their combs crooked and not in a line with the moveable bars. When the bees do this the bars are not moveable without loss. The combs in your sugar-made stock are also very thick and so overloaded with syrup that you fear that your take of honey in the autumn will be mixed with syrup. When the hive becomes fuller of bees the syrup will be eaten and the combs cut down to their usual thickness. If your bees have empty combs enough to breed in, you have nothing to fear. Do not give them much barley-sugar at present, rather cut the lids off some cells of sealed syrup near the bee nest, extending this work from week to week. Abbott's standard hives and all other hives require outward coverings of some kind to protect them from rain and the rays of the sun.

REMARKS.

13th.—Very bright in early morning, afterwards cloudy, with intervals of bright sunshine; cold wind, fine starlight night. Lunar halo 11.15 P.M.

14th.—Rather foggy and slight white frost in early morning; fine sunny day. Very fine series of solar halos and mock suns about 4 P.M.; moonlight night.

15th.—Fine morning, slight snow shower at 0.30. A true March day; dull and cold with intervals of sunshine.

16th.—Fine, sunny, but cold day.

17th.—Very cold in morning, but fine and sunny; dull afternoon and evening; rather warmer and cloudy towards night.

18th.—Fair day, at times very cloudy and dull; slightly rainy at night.

19th.—Fair morning with little sunshine; very cloudy and dull in afternoon; fine evening.

Another dry week, with very high pressure, and two or three sharp frosts.

—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 20.

We have very little now to offer in our market, old Grapes being nearly over. Strawberries, though a short supply, are more than equal to the demand. Trade very quiet.

DAMPING-OFF.

WHAT causes damping-off, and under what conditions is it most likely to occur? Does it occur when there is a superabundance of moisture in the atmosphere or soil, and are plants most liable to be injured by it in dull weather? Anyone who has taken the trouble to closely examine the subject, regardless of preconceived notions, will probably have arrived at conclusions very different from those who are not in the habit of thinking for themselves.

The quantity of atmospheric moisture has very little to do with the subject; indeed damping-off very frequently takes place when both atmosphere and soil are much too dry for the good of the plants; and an atmosphere which is sufficiently moist for plants to exist in will always contain ample moisture to cause damping-off if the other conditions are favourable to it. On the other hand, the tiniest and tenderest plant or cutting may be grown in a saturated atmosphere without damping. Do not, then, keep your tender plants dry and parched with the idea of preventing damping-off, you only encourage red spider and other insects as well as maladies, but look in another direction for both cause and prevention.

The mischief will be found to be caused rather in bright than in dull weather, and excepting when damping-off occurs from contact with decaying matter it will invariably be found to be caused by condensation of moisture on the plant or the soil surrounding it. We admire the thousands of tiny dew-drops clustering round the edges of the vigorous leaves of our forced Strawberries and Roses before they come to the flowering stage, and we do not object to see a few silvery beads occasionally in the morning on our Cucumber and Melon foliage—we know that the plants like the water, and that insects do not; but the same moisture would be almost fatal to Cape Heaths, Neapolitan Violets, and double Primulas, as well as the most tender seedlings and cuttings, if it lasted for any length of time.

As the exceptions are so few I may say generally that damping-off is caused by condensation of moisture, or, in other words, formation of dew. Condensation takes place immediately, if the air is still, on all bodies which are a certain degree colder than the surrounding atmosphere, and the dew remains on them till either the bodies are heated, the atmosphere cooled, or there is a brisk movement of air about them. Let me add that gardeners are not the only persons who are behind with this subject. Housemaids, cooks, schoolmasters, clergymen, and indeed all who have to do with habitable buildings, the food we eat or the clothes we wear, ought to be thoroughly acquainted with the subject, but I am afraid it is a fact that very few understand it. I am quite aware that I do not understand it myself, but as learners are always easier taught by their brethren who are also feeling their way, and are not so far ahead as to be out of reach of sympathy and kindred feeling, rather than by professors whose teaching, if more precise and correct, is generally dry and complicated, and consequently little read, that is my excuse for sometimes going a little beyond my

practical knowledge to touch on the region of theory, where I feel that if not always quite scientifically correct I may yet sometimes be the humble means of inducing others to think and even to teach.

"That nasty damp weather," says Mary Jane, "has made my fire-irons so rusty, I am so glad to see the sun shine;" and up go the windows to let in the soft south-western breezes. But Mary Jane is making a mistake; the air she lets in is considerably warmer than the room will add materially to the poor girl's hard work, and if the mischief ended there it would not perhaps so much signify. But fenders and fire-irons are only the tell-tales; they unfortunately do not receive a monopoly of the dew that is deposited. Metal bedsteads, plastered or painted walls (perhaps with clothing hanging against them), receive their share, although they do not rust. Mrs. Magnus, the cook, says the frost is just going out of her meat, and she must either cook it afresh or place it on ice. She knows the practical remedies from seeing them applied before, but she is not quite correct in her theory; when she does become so she will to a great extent be able to prevent the necessity for remedies. After a church or schoolroom has been filled with people for some time the walls are seen to be almost streaming with water, and the buildings are pronounced damp. Even the Ivy-clad cottage with open windows on a bright spring day after a spell of cold weather gets the same bad character. The reason is the same in every case, and the injury can be avoided in the same way—viz., by not allowing the beef, the walls, or the fire-irons to become colder than, say, 50°, or a little above the average temperature of the district and season.

Many people seem to have an idea that if a building is heated to a certain degree it is in a fit state for habitation as far as the heating is concerned, although it may have been quite cold for days previously and up to within half an hour of its being required for use; but I must tell them that there are sensitive people whose bodies are the most perfect thermometers, barometers, and hygrometers combined, and who are often exposed to great inconvenience and even constitutional injury from this general want of knowledge on the part of responsible persons. It would be far better not to heat at all than merely to heat the air while the walls, floors, and fixtures are icy cold.

I knew an accomplished noble lady who was the subject of ridicule on the part of her servants because when visitors were coming she would superintend the airing of the rooms herself for their reception, and her mode was very different to that practised by Mary Jane when using what she called her own common sense. The lady would insist on having large fires from early morning with closed doors and windows, keeping the room for a considerable time almost unbearably hot; then previous to the visitors arriving the windows would be thrown wide open for a short time, and the fire allowed to get down to a comfortable size. This I maintain is a true scientific way of making a room fit for human habitation.

I have run away from my subject of the damping-off of plants without pointing out the remedy, but the cause itself will suggest the remedy. Anything which will tend

to prevent great fluctuations of temperature will lessen the danger of damping-off. Shading during sunshine, giving air at the highest point of the pit or house as soon as the sun touches it, keeping the soil warm by means of bottom heat, are the three plans to be recommended separately or collectively under different circumstances; and there are two other plans which I do not recommend—viz., a generally high fire-heat temperature, and placing tender plants on upper shelves near the ventilators.—WILLIAM TAYLOR.

VEGETABLE CULTURE.

CHAP. XII.—THE LEEK.

THE Leek is a native of Switzerland and one of the hardiest inmates of our vegetable gardens. Although it is not so valuable as many other vegetables it is cultivated more or less in nearly every garden, and many amateurs take as great a delight in growing Leeks as others do in cultivating the choicest fruits and vegetables.

The remarks in these chapters on vegetable culture are mostly applicable to general cultivation; and as a chapter on preparing vegetables for exhibition will follow, the cultivation of the Leek for that purpose need not be referred to here.

For early Leeks a small quantity of seed is usually sown in a pot, pan, or box early in February, and placed in a frame or some slightly heated place, and when the plants are 3 or 4 inches high they are pricked out either into a sheltered border or frame amongst some rich soil. Here they remain until they have formed good-sized plants, and are then transplanted into the main quarters. Leeks of the very finest quality, however, and good enough for ordinary use, may be had from seed sown in the open ground from the beginning to the end of March. The seed is sometimes sown in the rows where the plants have to grow, and when they are large enough they are thinned out to 8, 10, or 12 inches apart. We seldom adopt this plan, but are perfectly satisfied with the following simple system: The Leeks are raised in a seed bed the same as Onions. The seed is sown broadcast. When the seedlings appear the bed is kept perfectly free from weeds, and if the surface soil becomes caked it is loosened with the point of a dibber. The seed should never be sown so thick that the plants will come up in close tufts, and they do not then require transplanting until they are finally planted. This should be done when they are 6 or 8 inches high. Where to plant and what soil to plant in must now be considered.

The first question is not of much consequence, as Leeks will grow anywhere provided they have plenty of good material to grow in. We never give our Leeks the best position in the garden, but we always give them the richest soil. A partially shaded place need not be avoided in planting if no better can be had. The ground should be deeply dug or trenched to the depth of 2 feet or more. The manure should be put down plentifully at this depth, because it is not much use having it nearer the surface than 6 inches, as Leeks are more inclined to root downwards than many other crops. It is not of great importance to have the soil turned up to the weather for some months previous to planting Leeks, as they do equally as well in soil dug over shortly before planting.

Having dug the soil deeply and manured it extra well, the plants may be planted in two ways and secure the same results. One is to take a dibble about 5 or 6 inches thick at the point and make holes 6 inches deep. In planting the roots are merely covered with a little soil, the holes being left open to allow the stem to expand freely. The other way is to draw drills 6 inches deep and dibble-in the Leeks along the bottom of the drills. In either case the plants should not be planted closer than 1 foot or 15 inches between the rows and 6 inches between the plants if fine produce is required. The object in planting Leeks deep is chiefly to make blanching the stem an easy matter, as the more a Leek is blanched the more valuable it is. Those planted in drills should have the soil levelled around them when they are large enough, and as they grow above this the soil should be drawn up to them, pressing it firmly about the stems. Those in holes are treated in the same way, only the holes generally become filled up by the soil falling in as the hoe is run between the rows, as it is necessary to do this several times throughout the season. Good Leeks should have their stems blanched from 6 inches to a foot. They should be quite fit for use from September until May. They require no attention during winter. When the ground they are growing on is wanted for other crops before the Leeks are all used they may be lifted and laid in closely

by the heels in any odd corner. The two best Leeks for any purpose are Musselburgh and Henry's Prize.—A KITCHEN GARDENER.

JUDGING ROSES.

[THE following communication arrived too late to be read at the meeting of the National Rose Society on March 5th, but is too important to be withheld from the public.]

A CORRECT estimate of the comparative excellence of Roses lies at the root of all Rose-growing and showing, and when defined and made known it becomes a standard for rosarians to aim at, and a law by which awards are to be regulated. "Our Society," therefore, surely does well in ventilating this subject so as to substitute recognised principles for vague notions, which latter afford neither information to the cultivator nor satisfaction to the exhibitor.

I assume that the National Rose Society aims at the encouragement of the highest cultivation of the Rose, by which term I mean the giving the most appropriate soil, situation, pruning, and general management. Then I maintain that the ascertained results of such cultivation ought to decide "the rules or principles that should be laid down for judging Roses."

Each Rose-grower can but give his own experience in this matter, and my own is as follows:—

Cultivation improves the size, intensifies the colour, beautifies the texture and foliage and strengthens the growth, but does not alter the form or shape, so that an exhibitor must depend upon his own judgment in selecting the best-shaped Roses, amongst which those ought to be most highly esteemed which are the grandest in size, the most brilliant in colour, and the softest in texture.

Objection will be raised by some against the value attached to size. According to them such Roses are "coarse overgrown monsters," &c. My simple reply is, This is the mere depreciation of what they either cannot, or at least do not achieve, for I can hardly believe that such persons when cutting for a Rose show have ever deliberately selected blooms of medium size and left behind them larger blooms in the same stage of growth. Anybody can grow medium-sized Roses, but we want a high standard of excellence to which the striving few only will attain, and we ought not to be satisfied with mediocrity. No: I do not advocate the exhibition of expanded Roses, which are past that stage of perfection at which they should be shown. Staring eyes, dropping petals, and loss of colour will tend to check and correct overblown Roses being staged. But supposing two blooms to be at the same stage of growth, that one is the best which has attained the fullest and amplest development. Roses should be exhibited at the maximum of excellence—just before they begin to deteriorate, and at that stage they should be as large as the limits of Nature will sanction. Take a large and a medium-sized Rose, and judge them as you would a course between two greyhounds—that is, at every turn, from the start to the death, and you will find that the medium bloom is very soon out of the race altogether. Of course, in magnifying anything we magnify its defects as well as its excellencies; but who would prefer a sight of the planets through an average spyglass, wherein they appear "very pretty," to one through a telescope like that of Lord Rosse's, which exhibits them in all their wondrous grandeur and interesting detail, notwithstanding defects proportionately enlarged.

As to colour and texture, I take it we are all pretty much agreed. Brilliancy and softness, the concomitants of good culture, are the results desired.

As to form, I have said that the shape of Roses is unaltered by cultivation; the exhibitor, therefore, must choose those Roses which are naturally the best shaped. I picture to myself a fellow rosarian taking me to task with didactic and patronising condescension. "Form, sir, is everything." His own Roses are symmetrical buttons, which have had no opportunity of developing either their excellencies or defects, but he speaks as though he monopolised the secret of producing Roses in any shape he chose, and expected others to obtain blooms of square or triangular form in consequence of their comparative ignorance or inferiority of culture!

But there are other matters to be borne in mind in judging Roses. There is no uniform recognised system of adjudication, and very often one judge knows nothing of the way in which another goes to work. A gives a number to each bloom; B counts the good, and C the bad blooms. D takes a bird's-eye view of matters; E asks himself which would sell the best;

F is partial to Teas; G is less so; H has no definite opinion, except that they are all grand lots and he is very fond of Roses; J is only Lord Noodle's head gardener; K has a personal bias which he cannot conquer; L goes by his common sense; and M varies his estimate at every different stand.

Correct naming is a matter which must be insisted upon. We must put down all tricks and deceits, unless we mean to go into horseracing. Oh! the shifts and chemises to which I have known some exhibitors have recourse in order to insert duplicates under fictitious names. Yet the judges have not always the time to look out for and detect these instances of dishonest staging, and sometimes they lack the necessary firmness to disqualify such exhibitors. In my opinion, therefore, some such printed instructions as these should be furnished to the judges:—

You are to adopt the system of giving a numerical value to each Rose from one to five according to excellence, and a majority are to agree to each such value. To these totals may be added from one to five marks per dozen Roses for taste, neatness, good foliage, and variety of colour in arrangement. The awards, of course, go to the highest numbers in their order, such numbers to be written on the prize cards attached. But if such totals come within one mark per dozen blooms, then the stands which they represent shall be adjudged equal, in which case the prizes shall be added together and divided equally.

The judges are to have regard to the following properties of the Rose in the order named:—1, *Size*, up to but not beyond that stage of growth when blooms commence to deteriorate—i.e., not overblown or decayed in colour. (Some Roses, such as Annie Wood, show the eye at a very early and stageable age, which is quite admissible.) 2, *Brilliance and depth of colour together with smoothness of petal*, not that a small bright Rose is to be preferred to a larger one less bright, unless the latter be really faded, but brilliancy is to be regarded as second only to grandeur of size. 3, *Shape*. Each variety retains its own form, but those Roses which are circular, full, convex rather than concave, with petals nicely arranged, are better than such as are otherwise.

Competent persons are appointed who will inspect the stands with a view to detect duplicates and wrong names. In case of unintentional mistakes, such as the staging of two Roses with the same name given, the exhibitor shall be called in and allowed to correct the error by staging another variety; but in the case of undoubted or even very questionable deceit, there must be unhesitating disqualification, which shall be written on the exhibitor's card.

In case of complaints or protests against the awards of the judges, none such can be entertained which relate to private estimates of excellence, but those only which disclose deceit or infringement of conditions otherwise undetected.

With a view to the instruction of rosarians in the principles of making awards, each set of judges may be accompanied by one such novice, who is not an exhibitor, who may seek information but not attempt to influence the judges. Application to be made through the Committee or Secretary, who might appoint such persons as honorary clerks to the different sets of judges to record the awards.—THE REV. E. N. POCHIN, *Barkby Vicarage, Leicestershire*.

NOTES ON VARIOUS TOPICS.

LET me first begin a somewhat discursive letter by thanking Mr. William Taylor for his very valuable article in your number of March 7th on Propagation by Cuttings. I have no hesitation in saying, that though he calls it hints to learners, there are many professional gardeners who might take a lesson from it. I have often said, and say again, that half the outcry raised against bedding-out (summer bedding-out I may say *par excellence*) is, owing to its having been taken up or adopted as a fashion, without proper provision or accommodation, or, as in many cases, without proper knowledge on the part of gardeners of the means of wintering, and afterwards of propagating, softwooded perennials. Bedding plants are too often valued as so much the thousand, and the plants which have to produce the stock in spring are kept on the makeshift principle, either starved in cold pits, or dried on shelves, or crammed into boxes, or (as in some cases) hung up by the heels in a cellar, and then, when the warmer days of the beginning of April begin to remind gardeners that bedding-out time is drawing near, a sudden impulse is given to forcing on the old stock, making cuttings how and where they may be had, placing plants under early Vines to be drawn up under dense

foliage, or one makeshift or another is adopted; and then the whole system of summer bedding-out falls into disrepute, because the plants by the first week in June have no real stamina to withstand the open air and the drying sun which we so often have between the 8th and the 21st of that month.

No persons ought to attempt to bed-out largely without they have means and appliances to boot, and will keep their stock plants in a rational way during the winter. Of course Geraniums require different treatment than Verbenas or Ageratums, just as much as a Heath or a Camellia will require different treatment to an Eucharis or a Dipladenia. All I wish to say at present is, that though some may praise up spring bedding with its Daisies and Pansies, or winter beds with little evergreens or variegated Kale, and though others may abuse Geraniums, Verbenas, Ageratums, Calceolarias, &c., because they interfere with the old perennials or alpine borders, &c., yet there is no real reason why every large garden should not have its separate divisions for Roses, perennials, alpines, &c., and yet still be able to devote attention to those plants, which, after all, with judicious care and treatment will give the best return for the trouble bestowed upon them—those which are popularly called summer bedding plants, and in this category I do not include those which eventually, or rather for a certain fashionable period (and fashions do not last long), threaten to monopolise the summer beds—carpet bedding plants. I hope before long the tedious monotony of so many Echeverias, Sedums, Golden Feather Pyrethrums, Alternantheras, Iresines, &c., *et id genus omne* clipped and kept into shape to make coloured patterns, will gradually die out. I should like to know at a rough calculation how many yards of beds in the London parks are edged with Sempervivums or Echeverias, varied every now and then by that still more objectionable plant the yellow Chickweed. However, I have digressed from my point, which was to thank Mr. Taylor for his very seasonable article, and to call attention to it; and I would also thank Mr. Brotherton, especially for his concluding remarks in his excellent article on page 202.

And now let me say a few words to "A KITCHEN GARDENER" in answer to his remarks (page 187) with regard to horse dung. I hardly expected to make him a convert, but I do not mean mere droppings, used first perhaps in the Mushroom house, but properly fermented manure from stables, mixed with manure from the pig yards. Fungus is a mere bugbear to bad gardeners, and it is simply a sign of bad management if ever fungus is allowed to injure the roots of Vines, however much decayed leaf soil or horse droppings may be applied. Neglect of proper watering either to inside or outside borders, or forgetting from time to time to examine their condition, and fungus may prevail, but no good professional gardener will ever be afraid of it. Of course your correspondent's preference for cow manure is a mere matter of opinion, and I am still free to differ from him and to think that unless the manure is from stall-fed beasts that have oilcake or rape seed, &c., given to them, that no cow manure can equal the manure from the stables, and in this I am borne out I believe by general analysis.

Now let me turn next to Rose judging. I certainly did not mean that my friend "THE HEREFORDSHIRE INCUMBENT" should for one moment fancy I thought he wanted exhibitors to study the tastes of the judges, but merely to say that to a certain extent it would be the case if the names of all the judges were published. I do not think Mr. Cant is right in thinking that Canon Hole would consider size as the last consideration [Mr. Cant inadvertently wrote the name of Canon Hole instead of Mr. Camm], nor do I think any judge would, but merely that size should not be considered as the *summum bonum* as in monster Mangold Wurtzels or Swede Turnips. Again, I agree with nearly all Mr. Gould says, but do not think it right to deduct points for bad blooms, but merely to consider them as out of the reckoning. On his system of giving only one point for each good bloom, taking off one for every bad, and not counting the medium at all, a stand of forty-eight Roses might be reckoned as seven or eight, or twelve Roses with four very good and four bad would be counted as *nil*. I do not see anything to improve upon what has so often been adopted where I have judged with others, giving three points for the best blooms, two for medium, one for those not so good, but not bad enough to cut out, and then cutting out all the really inferior, and giving an extra point to a very superior. By carrying this plan out a stand of seventy-two Roses should be considered as capable of receiving 216 points, a stand of twenty-four, seventy-two points, and the points might be put on the cards. Those not in the habit of judging

by points might think it takes longer to do this, but if the plan as mentioned by Mr. Camm (February 7th) is adopted, each judge taking it in turn to count the first-class blooms in the stands selected, the other two judges being ready to agree or not, and then equally to choose out the indifferent or inferior blooms, it does not take long to add up the points, and generally saves time at the last. It is only very rarely that two stands of Roses are so nearly equal that they have to be placed alongside each other and closely examined, &c. Mr. Gould's plan would, I think, fail in bringing the points given to each stand to a minimum, and not allowing sufficient scope for differences; and if, as he suggests, the points were to be put on the cards with his system, the public would be surprised that so few points were given. I do not mean to say at the bottom there is much difference intrinsically between us. In any large exhibition of Roses each judge ought to have a small note-book given to him and a pencil, besides the card for writing the numbers of the winning stands, in order that the points in those stands selected for competition should be put down. It is generally unnecessary, as a rule, with competent judges to select more than six or seven stands, even if there are from twenty to thirty competitors; and twenty-fours and twelves are usually far more difficult to adjudicate upon than the larger numbers.

I am going to conclude this letter with a few remarks upon "D., Deal's," notes on the Gladiolus. I do not profess to be a large grower of them, but I quite agree with him that the corms are liable to disease, and that mere exhaustion will not account for the deaths caused by an unfavourable season; besides, as in every case the old corms die and are replaced by the new ones formed on the surface of the old, it seems to me quite contrary to the habits and growth of the plant to speak of it as mere exhaustion, because those corms which are the most highly manured and most carefully tended are in the end more liable to the disease. Last year was no doubt, owing to a cold spring and wet autumn, a most disastrous season for Gladioli. My own experience in a light loam and a naturally dry soil is in favour of leaving the corms in the ground all the winter, merely covering them with ashes, and not to touch them till the end of March or beginning of April. I have certainly found much sounder and firmer corms with this plan than by taking them up in the autumn and storing them, as I am inclined to think many bulbs besides Gladioli suffer from being kept too dry. I am not an advocate, again, for burying the corms too deep, nor for applying too much manure. Except in the case of those who wish to prepare the flowers for the exhibition table and in the colder districts it is better to start the Gladioli in pots, even if under stages so long as they are not drawn up, rather than to plant dry corms direct into cold ground. But either Kent or Somersetshire are much more favourable for Gladioli than the north-east of Yorkshire.—C. P. PEACH, *Cannes*.

ASPARAGUS CULTURE.

ORDINARILY good Asparagus may no doubt be grown by ordinary people in ordinary gardens by the ordinary plan detailed on page 217 by "A KITCHEN GARDENER;" but if superior produce is desired I think a mode of culture somewhat different than that recommended by your correspondent must be adopted. The very best way of growing Asparagus that I am acquainted with is to grow it in rows not less than 3 feet apart, the plants or stools being 18 inches distance from each other in the rows. Provided the soil is the same, and the plan as recommended by "A KITCHEN GARDENER" of having the rows a foot apart is adopted, and if the mode of growing it in rows thrice that distance asunder is also carried out, I do not hesitate to say that produce of double the size and weight will be obtained by the latter system of culture. I have adopted both those modes of culture for several years, and every year's experience tells me that if superior produce is desired the old custom of growing Asparagus in thickly crowded beds is unsound in principle and disappointing in practice.

Unless robust stems are produced in summer, and the foliage of the plants is exposed freely to light and air, stout crowns cannot form, nor can large heads be produced in the following spring. By growing the plants in crowded beds a vigorous growth of stems and healthy and functionally perfect foliage are impossible. It must not be supposed that the leaves of Asparagus because they are small have no purpose to fulfil, and that it is immaterial that they be crowded, and consequently

undeveloped. The tiny foliage of this plant is as important to its well-being as the expansive leaves of the Vine are essential to high-class Grapes, and overcrowding in both cases is alike injurious.

Perhaps your correspondent may desire to know what I mean by vigorous summer growth. I mean stems 8 feet in height, as thick at the base as a stout walking-stick, and having branchlets commencing at 2 feet from the ground, and stout in proportion to the main stem. Growth of that character cannot be had by the plan recommended on page 217. Stems of the kinds specified I have had the pleasure of growing for several years past, and the heads succeeding them have always been much finer than those cut from beds, good as the beds were and are. Since the single-row system is regarded as the best it may be a matter of surprise that Asparagus is grown in beds at all. The explanation is simple. The beds are not mine. They are very old family favourites, and my instructions are to treat them well and to keep them in good bearing condition as long as possible. I do so, and have the gratification of hearing from the owner that they are as profitable now as they were forty years ago; but they are not so much crowded as if they had been planted after the manner recommended by "A KITCHEN GARDENER," nor are they managed precisely in the way he has advised.

But to return to the single-row system. It may be urged that the plan of having the rows 3 feet apart is an extravagant one, and involves a waste of ground. I do not think so. I regard ground as being wasted when inferior crops only are produced, and consider it utilised when it is made to yield produce of the first order of excellence. Of such is the Asparagus when grown thinly, but when crowded in rows a foot apart it cannot be superior, although it may be passable.

My plan in growing this vegetable on the single-row system is to have the ground well and deeply trenched, then throwing out trenches similar to preparing for Celery, and enriching them by a liberal application of manure, vegetable refuse, and a fair seasoning of salt. In these trenches the crowns are planted and the soil is partly levelled in. When finished the rows are in slight hollows, which are filled with tank water (liquid manure) two or three times during the summer. The ground is manured annually, and is dug between the rows, a covering of rich manure being placed over the crowns and there left to decay; the hollows are preserved in the act of forking over the ground. During the summer a few stakes are driven into the ground at convenient intervals along the rows. A strand of tarred twine is stretched from stake to stake, going up one side and down the other, enclosing the stems between the two rows of string, and this secures the summer growth from being broken by the wind. This work is speedily done and is important. But the ground between the rows of Asparagus is not wholly unoccupied. Early Lettuces and other salads, rows of early Spinach and winter Onions, are grown, and seeds of various kinds of vegetables are sown for raising plants for after-removal, and thus the entire space is occupied until the Asparagus shades the ground. So far from this system of growing Asparagus being unprofitable, I have a strong opinion that if the produce of the quarter were sold that scarcely any other portion of ground of the same size under different cropping would be more remunerative. That, however, is not the question. The real object is the providing of that which so many covet—large heads of Asparagus. Sprue can be had from the beds.

If ground is wasted at all in Asparagus culture it is, I think, when four rows are grown in 4-feet beds having alleys of only 18 inches in width between the beds. I am not surprised that such beds do not continue profitable over a lengthened period; indeed, I should be very much surprised if they could yield anything like superior produce during the period named of ten to twelve years. If there is one place more than another where the money value of land and crops are considered in the cultivation of vegetables, it is in the market gardens in the vicinity of London. The land there is highly rented, and it is only by superior cultivation (which is the true economy), that the cultivators can obtain an adequate return for their labour and outlay. Hundreds of acres of Asparagus are grown in the "market grounds" alluded to, some being grown on the level, but by far the most in highly raised beds. The rule is to have the beds 3 feet wide with 2-feet-wide alleys between them. Two rows of Asparagus are grown in each bed. Thus there are two rows in a width of 5 feet of surface, while your correspondent recommends four rows in 5½ feet. I much prefer the market growers' distances, and I fear that if they were to

grow Asparagus on the crowding system advised they would instead of continuing prosperous gradually merge into bankruptcy. The highly-raised beds are probably adopted partly because the ground is very low, sometimes flooded, and partly because they afford facilities for cutting the heads.

In the after-management of the beds, too, I think your correspondent is "behind the times," but that is a question that I cannot go into now. I agree that his remarks on the preparation of the ground are sound, and his hints on sowing the seed and transplanting the plants are reasonable, but the after and general mode of culture he has detailed is, I consider, obsolete or ought to be.—A NORTHERN GARDENER.

ROYAL BOTANIC SOCIETY.

MARCH 27TH.

ALTHOUGH this, the first spring Show of the Society, was later than usual, while, owing to the mild weather of February, Hyacinths were very early, yet excellent collections of these flowers were staged. Cyclamens were extremely fine, and these, with valuable miscellaneous collections, contributed to from one of the most attractive displays we have seen arranged in the corridor and conservatory.

In the open class for twelve stove and greenhouse plants in 12-inch pots, Mr. Wheeler, gardener to Sir F. H. Goldsmid, was placed first for moderate-sized specimens, consisting of *Ericas*, *Eriostemons*, *Tetratheca ericifolia*, *Phalenopsis Schilleriana*, *Anthurium Scherzerianum*, *Clerodendron Balfourii*, and *Imantophyllum miniatum*. Mr. Roberts was second with a collection of nearly equal value. For six stove and greenhouse or forced herbaceous plants in flower, monocotyledons excluded (open), Mr. Roberts was placed first with *Symphytum caucasicum*, *Primula cortusoides*, *Dielytras spectabilis* and *eximia*, *Hoteia japonica*, and *Doronicum austriacum*. Mr. Wheeler's collection was disqualified, *Amaryllis* and Solomon's Seal, which were included in it, being monocotyledonous plants.

In the amateurs' class for six greenhouse Azaleas in 12-inch pots, Mr. Ratty, gardener to B. Thornton, Esq., The Hoe, Sydenham, was in his old place—first, with admirably bloomed standards. Mr. James, gardener to W. F. Watson, Esq., Redlees, was second with freely grown bushes having fine flowers. Mr. Wheeler was placed third for large thinly-flowered plants. In the corresponding class for nurserymen, Mr. Turner, Slough, was in the premier place with well-bloomed moderate-sized plants of Prince Albert, Duc de Nassau, Queen Victoria, Roi Leopold, Juliette, and Seduction. In the open class for six Chinese Primulas Mr. James was first with small fresh plants; Mr. Edmonds, Hayes, Middlesex, second, one of the plants, Carmine Queen, being very rich in colour; and Mr. Ratty third with large plants, but all having white flowers. Mr. Roberts was the only exhibitor in the open class for six hardy Primulas. He staged some ordinary varieties of *P. acutifolia*, *P. marginata*, and the pretty white *P. nivalis*, misnamed *viscosa*. Mr. Turner was the only exhibitor in the class for six forced Roses, and was awarded the first prize for handsome symmetrical plants about 8 feet in diameter. The blooms were fresh and fine, and the foliage excellent. The varieties were *Souvenir d'un Ami*, Duke of Edinburgh, Edouard Morren, Madame Leachme, Madame Victor Verdier, and La France. In the open class for six Deutzias Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, was first with his cylindrically trained plants, 3½ feet high and 2½ feet in diameter—pillars of purity. Mr. James, Redlees, was second with dwarf bushes about 2 feet in diameter. In the class for six pots of Lily of the Valley (open) Messrs. Cutbush & Son had the premier place with excellent pots of large flowers; Mr. Douglas was placed second, and Mr. James third.

Cyclamens were numerous and superior. In the open class for twelve plants Mr. H. B. Smith, Ealing Dean Nursery, was placed first. The plants were splendidly grown, and the varieties were varied and excellent. Mr. Edmonds, Hayes, was second; and Mr. James third with very fine collections. In the amateurs' class for six plants Mr. James was first with dwarf vigorous plants, each averaging more than a hundred very fine flowers; and Mr. Lovesley, Isleworth, second.

We now come to the Hyacinths. In the amateurs' class for twelve plants, single spikes, Mr. Douglas was first, as usual, with fine spikes, but the foliage was rather drawn by the plants having been in flower for a long time. The varieties were King of the Blues, Mont Blanc, Koh-i-noor, Von Schiller, Macaulay, La Grandesse, Lord Derby, De Candolle, and Grandeur & Merveille. Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, was a very close second with dwarfier and fresher plants, with slightly shorter spikes. Grandeur & Merveille, King of the Blues, and La Grandesse were extremely fine. Both the collections were excellent, and contained the best spikes in the Exhibition. Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, was third. In the nurserymen's class Messrs. Cutbush & Sons were first; Mr. Hill, Alfred Street, Bow, second; and Messrs. Osborn & Sons, Fulham, third. The varieties were the same as those above noted with the addition of Gigantea, Grand Lilas,

Alba Maxima, General Pelissier, and Haydn. In the amateurs' class for twelve Hyacinths having any number of spikes either single or compound Messrs. Douglas and Moorman were again placed first and second respectively. General Havelock (blue) in the first-prize and Grandeur & Merveille in the second-prize collection were very massive. In the corresponding class for nurserymen the prizes were awarded in precisely the same order as in the nurserymen's class for single spikes.

TULIPS.—In the amateurs' class for twelve pots, four varieties, four plants in a pot, Mr. Moorman had the first place with admirably grown examples of Proserpine, Keyzers Kroon, White Pottebakker, and Vermilion Brilliant. Mr. Douglas was second, also with a good collection, but his Vermilion Brilliance were weak; the striped variety *Fabiola* was very good in this collection. Mr. Weir was third with dwarf plants. In the corresponding nurserymen's class the prizes were awarded the same as in the Hyacinth classes. Messrs. Cutbush's collection was composed of admirably grown and dwarf pots of Vermilion Brilliant, Proserpine, White Pottebakker, and Keyzers Kroon. Van der Neer was good in Mr. Hill's collection, and attractive were Rose Gris de lin, Princess Helena, silvery white, and Yellow Prince from Messrs. Osborn's. In the open class for twelve pots of Narcissuses, four varieties, Mr. Douglas was placed first for strongly grown examples of Newton, Queen of the Netherlands, Grand Monarque, and Grand Primo. Messrs. Osborn & Sons were second with well-grown dwarfier plants, Her Majesty in this collection being very good. Messrs. Osborn were the only exhibitors of twelve pots of Crocuses, and were awarded a second prize. In the open class for twelve bulbous plants distinct from any of the above Mr. Roberts, gardener to W. J. Terry, Esq., Peterborough House, Fulham, was the only exhibitor, and was awarded the first prize for a collection consisting of *Lachenalis*, *Muscari*, *Scillas*, and Dog's-tooth Violets.

Messrs. James Veitch & Sons exhibited a very fine collection of Hyacinths, for which an extra prize was awarded; the firm also had a similar award for a splendid bank of about eighty Roses. The majority of the plants were in 6 and 7-inch pots, each plant containing from six to twelve remarkably fresh blooms; the foliage also was excellent. Mr. B. S. Williams staged choice Palms, a small but brilliant group of *Amaryllises*, a few Azaleas, and other plants, and was awarded an extra prize. Messrs. Cutbush also had a similar award for a group of Azaleas and for an extensive and good collection of Hyacinths, Tulips, and Narcissuses. Azalea mollis in this group was very gay. Messrs. W. Paul & Son were worthily voted an extra prize for a remarkably fine collection of cut blooms of Camellias. The flowers were arranged with great taste, and were much admired. Messrs. James Carter & Co. staged an attractive group of a hundred Hyacinths. The plants were dwarf and sturdy, and many of the spikes very good; also very dwarf plants of *Dielytra spectabilis*, for which an extra prize was awarded. Mr. Lovesley, Isleworth, was awarded an extra prize for a collection of extremely dwarf Cinerarias. Some of the plants did not exceed 6 inches in height. The colours were also good. A similar award was made to Mr. Wiggins, Waverley Nursery, Tottenham, for Cinerarias.

Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., Avenue Road, Regent's Park, staged a splendid collection of Orchids. *Dendrobium litiflorum* was remarkably fine, as also were *D. crassinode Barberianum*, *D. Findleyanum*, and *D. Freemanii*. *Odontoglossum Alexandræ* was represented by one of the finest varieties we have seen, and *O. cirrhosum* was well grown and extremely attractive. *O. Pescatorei*, *O. triumphans*, *O. Andersonianum*, *O. gloriosum*, *O. Cervantesii*, and *O. maculatum superbum* were also in excellent condition. *Oncidium* were represented by *O. Weltoni*, *O. cheiroporum*, *O. Croesus longipes*, and *O. sarcodes*. *Angræcum sesquipedale* had six fine flowers. *Phalenopsis Schilleriana* and the brilliant *Sophranitis grandiflora* were included in the group. An extra prize was worthily awarded. A similar award was made to H. Little, Esq., Hillingdon Place, Uxbridge, for a small but highly meritorious collection of Azaleas: Leonie Van Houtte white; Roi d'Holland, glowing crimson; Dr. David Moore, very deep rose, double; Madame Louis de Kerchove, white, flaked rosy salmon; grandis, crimson; and Comte de Flandre, rosy purple, were very striking. Mr. Little had also an extra prize for a group of *Amaryllises*. Mr. James had an extra prize for a group of dwarf and well-grown Cinerarias; the plants were not more than 9 inches in height and had heads 2 feet in diameter. Similar awards were made to Mr. Smith and Mr. Clarke for remarkably fine groups of Cyclamens; also to Mr. Ratty for a well-grown plant of *Imantophyllum miniatum* with six fine heads of flower.

Certificates were awarded to Messrs. James Veitch & Sons for the scarlet perpetual-flowering Carnation A. Alégaire; also to Hyacinths King of the Blues, Grand Maître, and Queen of the Blues; for the fine deciduous Magnolia Halleana, for Pavonia Wiotii, and for the stately yet elegant Fern *Microlepia hirta cristata*. Mr. B. S. Williams had a certificate for the same Fern, also for another Fern with the formidable name of *Anemidictyon phillytides tessellata*. It is a distinct Fern with large Pteris-like fronds, and produces spikes of inflorescence after the manner of *Osmunda regalis*. Messrs. Veitch further had certificates for

Odontoglossum cirrhosum var. *Klabochorum*, richly spotted; and for *Cypripedium porphyreum*, the result of a cross between *C. Roezlii* and *C. Schlimii*. It somewhat resembles *C. Sedeni*, but is lighter in colour than that valuable variety. Messrs. Osborn and Sons had a certificate for *Abutilon Lady of the Lake*, a free-growing and flowering variety having bright rose-coloured flowers with dark pink veins. Similar awards were also made to Mr. Smith, Edmonton, for gold-laced *Polyanthus Duke of Wellington*, and to Mr. Clarke, Twickenham, for *Cyclamen Brilliant*; colour ruby crimson, very rich.

The Duke and Duchess of Teck and a large company of visitors attended the Show.

NOTES AND GLEANINGS.

THE spring Show of the MANCHESTER BOTANICAL AND HORTICULTURAL SOCIETY, which was held in the Town Hall, Manchester, on the 19th inst., was, we are informed, highly successful both as regards the extent and quality of the exhibits and the attendance of visitors. The Society's gold medal was awarded to Mr. Leech, Fallowfield, for Orchids, and the silver medal to Mr. Joseph Broome for miscellaneous plants. Certificates were granted to Messrs. Standish & Co., Ascot, for fine pots of Lilies of the Valley and excellent plants of *Chorozema cordata splendens*; to Mr. B. S. Williams, Holloway, for a collection of Cyclamens, also for *Azalea Princess Maude* and *Dracæna Berkeleyi*; to Mr. Henry Shaw, Buxton, for *Dracæna Goldiana* and *Rhododendron Dalhousianum*; to Messrs. G. and W. Yates and Messrs. Caldwell, Knutsford, for miscellaneous collections of plants; to Mr. Leppoc for Cyclamens; and to Mr. S. Barlow, Middleton, and Messrs. Zocher and Schneevogt, Haarlem, for Hyacinths.

THE following are among the ORCHIDS now flowering in Messrs. Veitch's collection at Chelsea. *Dendrobium Wardianum*, crassinode, Devonianum, bigibbum, cambridgeanum, densiflorum, and lituiflorum, all of which are very fine, the first three splendid. *Odontoglossum Cervantesii*, triumphans, cirrhosum, some very fine varieties; *Andersonianum*, luteo-purpureum, *Pescatorei*, cordatum, prænitens, crispum, *Hallii*, *Roezlii*, *Alexandrae*, and the distinct and charming *O. roseum*. Several fine *Vandas* are in flower, including *V. cristata*. *Oncidium fuscum* and *sarcodeum* are attractive, *Cymbidium eburneum*, *Angræcum citrinum*, *Cattleya citrina*, the small wax-like Australian Orchid *Sarcophilus Fitzgeraldi*, *Epidendrum Wallisi*, several *Phalaenopsis* and *Cypripediums*, and a few *Masdevallias*, including the grotesque *M. chimera*, are all ready for Ghent, and, weather permitting, would form a very fine group; but the frost winds and snow squalls prevailing will perforce keep many valuable plants in England that otherwise would have been at the Great Exposition Internationale during the first week of April.

A WHITE FORCING ROSE of great value is *Coquette des Blancches*. We recently observed it in Messrs. Veitch's fine collection at Coombe Wood, and no Roses were more beautiful, and no variety was flowering more profusely. It is a hybrid *Noisette*, and resembles *Baronne de Maynard* and *Boule de Neige*, but those varieties will not force. *Madame Lacharme* is proving to be a forcing Rose of the greatest merit, and so is *Duchess of Vallombrosa*. *Fortune's Yellow*, as forced, was very thin and unsatisfactory. *Belle Lyonnaise* is a grand Rose for walls or pillars.

A CORRESPONDENT, "W. K.," informs us that of *EUCALYPTUS GLOBULUS* he has five three-year-old trees growing by his croquet ground. He lives near Arundel in Sussex.

A GERMAN VITICULTURAL SOCIETY has just been formed at Cassel. For the present the Society intends to take up two important matters—viz., 1, discovering the best method for the destruction of phylloxera, and 2, the suppression of the secret manufacture of wines by artificial means.

A CORRESPONDENT, "RAMALHO," says, "I have had some seed sent me from Australia of a shrub called *ROSELLA*, which they say is covered with crimson flower buds, of which they make a most delicious preserve." Can any of our readers tell what the proper name of the shrub is?

MR. WILLS the florist used nearly three thousand Tea-scented Roses in the floral decorations on occasion of Miss Rothschild's wedding last week. It was a very pleasing and happy idea of Miss Rothschild to surround her magnificent wedding presents with thousands of lovely Rose blooms. The great difficulty was to obtain them. Mr. Wills had to apply to nearly every Rose-grower in the three kingdoms, besides

scores of private growers. Besides the Roses he had a splendid display of *Odontoglossums* and *Phalaenopsis*.

PERHAPS in no practice of gardening are errors more frequent than in SOWING SEED OF TENDER PLANTS TOO EARLY, and in frames and other structures which are highly heated. Seeds of half-hardy annuals, such as Stocks, Asters, Marigolds, Phlox Drummondii, and other plants, also of Tomatoes and Vegetable Marrows, are too often sown early and thickly when sufficient means are not afforded for growing on the plants in light structures so as to insure a stout, dwarf, healthy habit of growth. Thousands of plants are spoiled annually and much seed is wasted by over-haste in sowing, and necessarily leaving the plants for a considerable time crowded together in seed-pots and boxes. Far better is it for those whose glass conveniences are limited to wait until April before sowing seeds of plants of the character named, and then to sow them thinly in frames which are moderately heated; the plants then grow on unchecked and are much more satisfactory than if the seed had been sown two months earlier. Much injury is often done by sowing seed in high temperatures and subsequently transplanting the seedlings into the cold soil of the garden. This applies to both flowering plants and culinary vegetables.

MR. HENRY F. FOY writes as follows on *LAPAGERIA ROSEA*:—"I have a plant in a box 3 feet by 1 by 2. It has been in it about four years, and the branches now half cover the conservatory roof. It began flowering about the end of August, and although the thermometer sometimes went down to 32° the plant continued in beauty until nearly the end of February. Sometimes there were nearly three hundred blooms in colour at once. I wish to know whether I may top-dress it with 2 or 3 inches of last year's Cucumber bed. I noticed someone in the Journal was surprised that a *Lapageria* flowered on the old wood; mine always does."

AS winter and spring flowering plants few are more useful than *EPACRISES*. The number of varieties is so great as occasionally to be bewildering. A few of striking decorative value are the following, which were recently flowering in the nursery of Messrs. W. Paul & Son at Waltham Cross. *Devoniensis*, bright red, very gay; *Fulgens*, salmon pink, very fine bells; *Alba odorata*, white; *Archduke Stephen*, red, fine; *hyacinthiflora candidissima*, a well-known and valuable white; *impressa coccinea major*, scarlet, very bright; and *Walkerii*, magenta pink, distinct in colour and attractive. Those varieties grown in masses produced an imposing display.

THE Plum trees in the ORCHARDS in THE THAMES VALLEY are now in full blossom. The trees present a beautiful appearance, but it is greatly to be feared that the severity of the frosts which have recently occurred will seriously interfere with the setting and swelling of the fruit. Plum blossom is, however, proverbially hardy, and as the soil and atmosphere were dry when the frost occurred, sufficient of the blossom may have escaped destruction to produce what has not been seen during the past three years—fairly good crops of fruit. The Apple trees are profusely studded with blossom buds which are swelling too quickly, but Pear blossom is comparatively sparse. The hardy fruit crop of the year is undoubtedly in great jeopardy, notwithstanding that the dull cold weather which has lately prevailed has sensibly retarded the expansion of the blossom.

MR. THOMAS JOHNSON, gardener to Colonel Battersby, county Meath, for sixty years, died lately at the age of 106. He retained all his faculties to the last. Longevity in his case appears to have been hereditary, for his father, it is said, died at a still riper age, namely 115 years.

THE mild winter has been extremely favourable to the winter and spring GREEN CROPS. Broccoli have been and are abundant and good, and Cabbages promise to be plentiful and early. Hundreds of acres of them in the market gardens around London are looking extremely well, and in some instances cutting has already commenced. The Cabbages in the market fields are never earthing up in the manner usually practised in gardens, earthing being considered not only unnecessary but injurious, by preventing the rains penetrating the soil around the stems. Instead of "one earthing-up and done with" the ground is continually stirred amongst the plants; once a week at least if weather permits the ground is hoed, the expenditure of labour being found especially profitable in promoting the growth of the plants and accelerating their bearing. It is singular that while vegetable crops are grown so excellently along the banks of the Thames west of the

metropolis, that Brussels Sprouts will not succeed, and their cultivation has been practically banished from the fertile district in question.

— THE *Sydney Morning Herald* states that in New South Wales and Victoria at a considerable depth below the surface of the earth the RELICS OF A FLORA which has long since passed away are being gradually brought to light. From these remains of primeval vegetation it would appear that where Gum trees and Apple trees now prevail a very different order of trees once flourished. In the appendix to the report of the mining surveyers in Victoria for 1877, a new fossil of the genus *Wilkinsonia* is described. Specimens of this (*W. flaminata*) were procured at a depth of about 130 feet, under basalt at Benerece, and also in the blacklead of Gulgong at a depth of 175 feet, beneath a layer of basalt. Baron F. von Mueller, to whom the specimens were submitted for examination, is of opinion that the plant producing the remarkable fruit now existing only in a fossilised state may have belonged to the order of Sapindaceæ. He also observes that "the fossil treasures of that particular period, the upper pliocene, are by no means exhausted."

— THE CINERARIAS in Mr. Watson's garden at Isleworth are this year remarkable for the excellence of the newer varieties. For years Mr. James has devoted special attention towards improving this indispensable spring flower, and he has certainly good reason to be satisfied with the results of his labours. The flowers are not so remarkable for their great size as for their excellent form, great substance of petal, and rich and varied colours; the plants are also extremely dwarf and sturdy in habit. The self-coloured varieties are extremely striking, ranging from satiny rose to glowing magenta and crimson; some of the blues and purples are also remarkably fine. Out of the hundreds of plants grown not a dozen are to be found of inferior quality, and the flowers of these are being cut for vase decoration. Nearly all the plants are flowered in 48-sized pots. Mr. James is strongly opposed to the early sowing of Cineraria seed. His mode of culture is to sow about the end of July, and to grow his plants rapidly and without check through the cool autumn months. The *Calceolarias* are in splendid condition. The plants are never stopped, but branch out naturally and form specimens 3 feet in diameter and about half that in height. The plants are remarkably dwarf and vigorous. *Cyclamens* have been in great beauty for the past four months and are beautiful still. The strain is an excellent one, the white varieties being very pure, and the darks rich. Mr. James's practice is to sow the seed of these plants as soon as it is gathered.

— THE noble range of glass in SIR HENRY PEER'S GARDEN AT WIMBLEDON HOUSE which has hitherto been devoted to plants will in future be chiefly utilised in fruit culture. Three of the houses have been planted with Vines, two with Figs, and one with Bananas. The Fig houses have indeed undergone a transformation. Only one tree has been planted in each house, but these were large enough to occupy the trellis as soon as planted. They are old trees which have been taken from the garden walls. One of them covers a trellis 30 feet long and 15 feet wide; and the other is nearly as large. Not only have these immense trees apparently become established since November, but many of the autumn-formed fruit are swelling freely. It has been no light task to remove and get these trees into the houses; but Mr. Ollerhead is a gardener who combines skill with energy, and he is probably never so happily engaged as when facing a difficulty and overcoming it. First-rate practice is to be found in these gardens, which cannot be visited without yielding useful hints worthy of being recorded.

ROSE JUDGING.

MY article on this subject certainly had the desired effect of extracting valuable information from many readers of the Journal, and among others the opinion of one who rarely writes to you.

After the various opinions are sifted it will be seen that there is only one point upon which there is much difference of opinion, and that is the matter of size. The northern growers Mr. Pochin, Canon Hole, and my genial friend C. P. Peach, have all a hankering after size, perhaps sometimes even at the expense of form. And this is not to be wondered at, for they live where the soil is so strong and rich and well adapted for Briar Roses, that they are able to produce larger

blooms than we are in the south or west; but if the subject is impartially considered I think that the verdict will be given to us. The remark of Mr. Pochin's, mentioned by Mr. Peach, "that this might have been that, but that could never be equal to this," alludes, I suppose, to some stand of very large blooms, but coarse and past their best. Undoubtedly I and those who think with me—and I think I can claim such rosarians as Mr. George Paul and Mr. Benjamin Cant, and Mr. Baker and Mr. Jowitt among amateurs—would give the preference to the stand which contained the smaller but fresh and more symmetrical blooms.

I seem, so far as the letters that have appeared in the Journal may be taken as a guide to general opinion, to be in a minority of one with regard to the estimation which I place on Teas. There is no doubt much in what Mr. Baker says as to the Teas having a class of their own, but in reply may I remind my good friend that latterly a horrible custom has been creeping in of a class for Hybrid Perpetuals alone? so that if this ever-to-be-deprecated innovation takes firm footing the poor Teas will have lost their privilege.

"D., Deal," thinks no doubt he gives me a rap on the knuckles by informing me that *Maréchal Niel* and *Cloth of Gold* are Noisettes. I am aware that the latter undoubtedly is of that family, but there is considerable doubt as to the former. Canon Hole calls it, I think, a Tea Noisette, but it certainly partakes much more of the Tea than Noisette family. Apart from this, it is highly inconvenient when writing on a given subject to repeat time after time the full title of the class, Teas and Noisettes, though everyone knows that when speaking of Teas I include Noisettes.

I was unable to be at the General Committee Meeting of the National Rose Society on Shrove Tuesday, as we have no late train on our line, and so I could not get back in time for service on Ash-Wednesday, but I hear that some rules for judging were drawn up. When these appear we shall be able to discuss them in the columns of the Journal. Meanwhile I suppose the last word has been said on this most important subject.

Before concluding this letter I should like to say a word upon the loss the Rose world has sustained in the death of one of our best judges, and one who in particular gave attention to Tea Roses. John Keynes of Salisbury loved Roses with all his heart, and grew them too in a way that, considering the disadvantages under which he laboured, was highly successful. He had a miserable soil—in fact I do believe it is as bad as mine, and yet he managed to grow fair plants. The *Manettis* were growing literally in a bed of stones; and though the plants never attained to such dimensions as those from such soils as King's Acre or Cheshurt, yet they were always well rooted. He managed to grow good standards by combining Dahlia cultivation with that of the Rose. The soil was very richly manured for Dahlias in a sheltered spot by the river, and after the Dahlias were removed the Dog Roses followed, and they did remarkably well in this rich soil; after these were sold off the Dahlias followed. So that every third year the soil was richly dressed, and also received the benefit of a change of crop. There is no more necessary condition in Rose-growing than this—viz., that the same soil should not be devoted for more than two or three years to Rose cultivation. Mr. Keynes was a most kind and genial host; he was always ready to welcome strangers as well as friends at his nursery and house. When I first commenced Rose-growing I wrote to ask him if I might come and see him. He gave me a ready invitation and a warm reception, told me everything I wanted to know, and entertained me most generously. He was a very shrewd man of business, and has, I believe, left a large fortune. His shrewdness showed itself to me in an amusing manner on one occasion. I was asking him all sorts of questions, and the dear old man was giving me the best information, when suddenly he turned round, fixed his penetrating eyes on my face and said, "You don't intend to set up against me, do you?" I assured him on this point, and he regained his composure and doubted me no more. The last time I saw him was on the day of the National Rose Society's Show at St. James's Hall. He had been judging the small classes and travelled home with me. It may be a pleasure to Mr. Smallbones to know that he agreed with me as to the marvellous perfection of his stand of twelve Roses which won your cup.

Although there is no Rose that bears his name, nor, indeed, has he introduced any with the exception of the sport from the Tea Rose *Madame Willermoz*, Letty Coles, yet his name will long live in the memories of Rose-growers, and his genial

face be much missed from our great Rose exhibitions, for we can ill afford to lose one from the small but select band of great exhibiting rosarians. Let us hope that his successor will continue to exhibit that queen of flowers with which the name of John Keynes has been so long and honourably connected.—WYLD SAVAGE.

IBERISES.

At this period of the year these extremely hardy and early dwarf perennials are just unfolding their flowers, and are making borders and rockeries cheerful by the dense profusion

Fig. 36.—*Iberis ciliata*.

of white trusses which the plants produce. Worthy of being added to the species which have been recently alluded to in your Journal is *I. ciliata*, which is distinct both by its slender growth and rosy purple-tinted flowers. It is particularly suitable for occupying a sunny position on rockwork, and should have a place in that interesting appendage to the garden the alpinery. It is a plant that cannot endure being crowded, neither should it be replanted more frequently than can be avoided. Rather than attempt to increase it by division I prefer striking cuttings in gentle heat. They root quite readily when inserted at this period of the year, and make small flowering plants by the following spring. It may also be increased by seed sown as soon as ripe.

This little plant, says the "Botanical Magazine," is a native of Caucasus, growing in the vicinity of the hot springs of Mount Constantine. It may easily be confounded with *Iberis Garreuxiana* of Allioni, which is considered by Willdenow as a variety of *sempervirens*, and is the plant usually met with in our collections under the name of *Iberis saxatilis*; but *I. ciliata* may be distinguished by the leaves being under all circumstances minutely ciliated and the stem hairy near the flowers, whereas in *Iberis Garreuxiana* the whole herb is quite smooth.—D. D.

ROSE SHOW BOXES.

WHEN a certain famous surgeon was consulted on his special subject his invariable answer was, Buy my book! "PLOUGH-BOY" and other intending exhibitors can hardly do better than "buy" Canon Hole's book, or at any rate consult it as to the best form of box. That given at page 243 (edition fourth), leaves very little to be desired in the way of utility. The box figured there is a twenty-four box. For a beginner

perhaps one to hold twelve might be better. The older-fashioned boxes (shown in *Journal of Horticulture* of February 14th, 1867, in an article written by Mr. A. H. Kent), are cheaper and more handy, but labour under the disadvantage of having no cover; also, as the holes for the tubes are cut there through the surface, it is not possible to re-arrange the box so as to contain a different number. If the interior of the box be kept perfectly clear, and the tubes imbedded in bran or sawdust, a twelve box may be made a six, or a twenty-four box without much difficulty re-arranged for twelve triplets, the usual surface of moss being placed above afterwards by way of bedding for the Roses. It will be obvious that these remarks are intended merely for beginners and small exhibitors.

It will be seen in the forthcoming schedule of the National Rose Society that the attention of their indefatigable Secretary, Mr. Dombain, has been directed amongst other things to this very question—namely, the improvement or further development of exhibition boxes. A prize proposed by him and accepted by the Committee is about to be offered. "For the best exhibition stand other than those in ordinary use, and covered with material other than moss."

LOBELIAS FROM CUTTINGS.

LOBELIAS from seed are so unsatisfactory that I am now depending on plants from cuttings only. A few good varieties—seedlings—were selected for growing a couple of years ago, but St. Martin's has superseded these. Magnifica is also grown. Do any of your correspondents or readers know of any sort having the same habit as the last named and better? also if there is any variety of the same shade of colour as Omega, but with a good habit of growth? I shall be obliged by information.

Returning to the raising of plants of Lobelias from cuttings. These are so easily managed both as regards wintering the stock plants and propagating them in spring that it is doubtful if anything is gained in an economical view by raising seedlings. The real difficulty with many lies in wintering the stock plants. It merely requires a dozen or two plants to be potted when the rest are consigned to their summer quarters in the flower garden: 5-inch pots will be large enough. These may be flowered during the summer and autumn in a greenhouse, and at the approach of winter transferred to quarters alongside Verbenas, &c., where they can be kept in a gently growing condition throughout the winter. I cannot exactly say how many plants each pot will furnish by the time planting-out season comes round—fifty at least from each may be safely reckoned on for a first batch in February, and propagation may proceed up to ten days before they are required for planting. Plants taken from the beds in September, pulled in pieces and potted, with same winter treatment as above recommended, do very well. Whole plants potted from the beds are prone to decay in the centre of each, which decay extends till not a remnant is left alive.—R. P. BROTHERSTON, *Tynningham*.

HINTS ON LANDSCAPE GARDENING.—No. 2.

VILLA GARDENS.

LAYING-OUT of villa gardens is a work frequently beset with difficulties that are unknown in the treatment of large gardens. A very limited area of space in villa enclosures, the stiff uncompromising formality of boundary lines, and the proximity of other houses being all sources of annoyance that are not often overcome successfully, and yet they ought to be if a due amount of skill, taste, and judgment is brought to bear upon the work. No doubt the site and surroundings of every garden has its own peculiar features, requiring special study in order that they may be dealt with successfully, but a few hints devoted to a general consideration of the difficulties enumerated cannot fail to be useful to a large and important section of the community.

Now, the first object usually sought for is privacy, and in striving to obtain it the entire garden is frequently spoilt. "My garden is overlooked by my neighbours' windows. What fast-growing tree can I plant to shut them out?" is a query to which the answer, but too often given and acted upon, is "Plant Lombardy Poplars," and so it comes to pass that, instead of concealing the angular outlines of the garden, they are made doubly offensive by being defined by a row of trees chosen in order that the garden may not be encroached upon by wide-spreading branches, the advantages and pleasure to be derived from cool shade in summer being apparently quite lost sight of.

Let us see if we cannot find something among the ample store of materials ready to our hands wherewith we may not only make an enclosure but impart an ornamental feature throughout the year—changing in its aspect with the seasons, and yet never losing the elements of beauty. To this end we will avoid straight lines or rows of one kind of tree. Tall-growing trees shall be planted near the boundary of the garden, and also be brought boldly forward into it, mingled with shrubs deciduous and evergreen arranged with due regard to height, size, form, and colour; not in such precise gradation as to appear severely formal, but in broken yet graceful order, rising and falling in flowing rounded outlines.

Near Blackheath, at The Firs, Lee, the residence of J. W. Larking, Esq., there is a garden which is a striking example of how thoroughly well privacy may be secured in a small garden much overlooked by the windows of adjacent buildings. There

is more real beauty in this confined space of an acre or two than one often meets with in large gardens. Let us glance at its most salient points. Close to the house are a few small beds, made gay with flowers in summer and planted with dwarf shrubs in winter. They stretch along in front of the windows and occupy very little more space than an ordinary border. Beyond the beds is an unbroken sweep of lawn extending nearly to the end of the garden, but not quite, raised banks thickly clothed with shrubs shutting in the end of the lawn, and along the sides there are shrubs and trees thick set behind, but so much broken along the front that strips of lawn run in among them, forming charming nooks and glades so well contrived that one is almost led to think they lead to other lawns. Some of the shrubby promontories come boldly out upon the turf, ending in a rounded point left bare for flowers. These spaces so placed, with the soft green turf in

Fig. 37.—MR. LARKING'S VILLA GARDEN.

front and shrubs behind, are the very perfection of a flower bed, bright colours with such surroundings being much more telling than they ever can be in a detached bed.

One nook near the house and somewhat apart from the lawn is so beautiful and affords such a valuable lesson that I send you a photograph of it, which Mr. Larking has kindly placed at my disposal. It has a square outline, and is hardly so large as most of the front courts to which attention was called on page 199, and yet it is a model of tasteful arrangement. It is not often one can approve, much less admire, the manner in which vases or statuary are introduced into confined spaces, but here the Naiad and little pool of water impart so much life and expression, and such an air of grace and quiet beauty pervades the charming little miniature, that all thought of criticism is lost in the admiration which cannot be withheld.

In other nooks and corners various other features present themselves in a natural and therefore pleasing guise. A little pond for aquatics, a Fern bank, mixed groups of choice shrubs and hardy Heaths, rock beds with appropriate hardy plants and dwarf spreading shrubs, a bed of Clematis Jackmani in an inconspicuous position, and yet so placed that when its flowers open they cannot fail to attract attention. Lofty trees also play an important part here, some very large Elms and two of the finest Hickories in this country being most conspicuous. Another tree of lowlier growth, but quite as im-

portant in its way, is singularly well placed at a corner near the house. It is the Snowy Mespilus (*Amelanchier Botryapium*), a standard some 20 feet high, with a spreading head of fine spray that is laden with white blossom in spring.

As seen from the house the bank of shrubs at the extremity of the lawn appears like a boundary of the garden, but as we approach it we find an opening in the bank, not in the direct line of sight, but on one side, whence a path takes us in a diagonal line to a door in a wall; we open it and meet with a delightful surprise, for we enter an exotic fernery—a large lofty building containing thousands of Ferns, but not an inch of staging, for the good taste we admired so much in the open garden is even more conspicuous here. Out of banks and mounds thick set with exotic Mosses spring the Ferns in such profusion as is absolutely bewildering. Giant Tree Ferns towering aloft spread out their huge frondage over a multitude of rare kinds of lowlier growth, all flourishing with a vigour unknown to plants in pots, for here most of the plants are turned out into mounds of rich soil, and the roots are suffered to ramble in it unchecked. Our enjoyment of the fernery was enhanced by the sight of flowers in a winter garden adjoining it, the plants there also being planted or plunged in raised beds and mounds, in pleasant contrast to the staging and formal rows of plants in pots that is usually seen in such buildings. I am tempted to dwell upon these buildings and

their contents, but must not wander farther from the subject of these notes. Villa gardens, however, are so important that I must return to them in my next communication.—EDWARD LUCKHURST.

THE NATIONAL ENTOMOLOGICAL EXHIBITION.

(From a Correspondent.)

HAD I forgotten my destination last Wednesday (20th inst.), the circumstance that a party of men were carrying the familiar advertising boards with a figure of a butterfly displayed thereon would have reminded me that a sight quite unusual was to be witnessed at the Royal Aquarium, Westminster. It was added that £20,000 is estimated to be the money worth of the specimens on exhibition. Perhaps the amount seems preposterous to some, but I do not think that it is an overvaluation. Insects are likely to become more valuable as the years go on and a taste for show collections increases, when they are irreplaceable or nearly so; for instance, specimens of the large copper butterfly, really British, may fetch a sovereign now, but as there never can be more of them they will eventually rise perhaps to £5 each.

At a first glance over the list of names of exhibitors we shall be possibly surprised at the absence of some of our best-known entomologists, and one reason for this is that these, at least the majority of them, are less likely to be prepared to get up show cases for an exhibition than some who are quite as indefatigable, but whose fame is limited to a small circle of friends. Thus, were Doubleday or Newman living now I doubt whether they would have been enrolled as exhibitors, though always willing to allow entomologists to make an inspection of their well-nigh superb collections. Others, again, who have done the science of entomology much service have not been collectors, but rather observers or anatomists. A very large amount of thanks is certainly the due of those gentlemen and ladies who have at a risk of injury placed before the public a show of insects that is hitherto unrivalled; and though some of these exhibitors are modestly set down as artisans or working men, I would fain believe that every entomologist is a gentleman.

The arrangement of the cases and other objects exhibited, large and small, is not on the whole to be complained of. It has been a matter of necessity, through the limitation of space, to put some things in the background which the entomologist, if not the ordinary sightseer, would like to have had brought closer to him. (I notice, by-the-by, that not a few entomologists are long-sighted, and though they can see an insect a dozen feet off, when they have it in hand they are apt to bring it within a few inches of the nose for close inspection.) Persons inclined to be fastidious may object to the display made in the Exhibition by those who are dealers in insects and insect apparatus. Under the circumstances, perhaps, a little puffery is pardonable, and it is an honest truth that science owes much more to some of those who are professional collectors than she is aware of or is likely ever to pay. Looking at some of the tasty articles shown as part of the collector's outfit, one is almost of the opinion of the old angler, who was so charmed with the rod and flies he generally used, that he said the fish ought to be delighted to come and be caught! Some of our best entomological captures, however, have been made with rough and home-manufactured implements.

British entomology is, speaking generally, more prominent in the Exhibition than exotic entomology, and in the latter division, as we should expect, the butterflies and beetles make the chief display. With the exception of Europe, and there even much remains to be done, our present knowledge of the insect races of the world is in an unsatisfactory condition. In the case of the moths, and other night-fliers particularly, it will not be increased until there are more residents in other lands who will take the pains to breed or rear species. The best foreign collections are those shown by the Rev. A. Walter and General Ramsay, and by two dealers, Messrs. Cook and Meek. Mr. S. Stevens has sent his magnificent collection of British butterflies with many rarities and varieties, and the fine collections contributed by Messrs. Wellman, Elisha, and Machin deserve much praise. The minute species belonging to the last gentleman must have required immense patience in setting. Probably many will consider the gem of the Exhibition is the series of cases belonging to Lord Walsingham, who has preserved with marvellous dexterity a host of caterpillars common and rare. Mr. Gedde also sends instructive cases of caterpillars and transformations. Mr. Tuely's collection of Lepidoptera obtained in his house, garden, and grounds at Wimbledon proves the richness of some London suburbs, for there are about 350 species, seventeen of these being butterflies. It would also have been interesting to have had a show of other species occurring thereabout, say on the well-known common and in Coombe Wood. Of local insects we have some valuable illustrations, as in a Perthshire collection and in one from the fen districts. By the joint labours of three gentlemen, Dr. Power and Messrs. Stevens & Champion, we have a splendid array of British beetles containing many rarities.

But, passing over unavavoidably other collections that also deserve commendation, I must remark with regret that there is not much

that is novel or valuable in economic entomology. Two small cases show the ravages of the Goat Moth (*Zyaleutes Cossus*), and another shows the work of small larvae on Fir cones and Fir bark. In addition to these the horticulturist may look with advantage on a few cases illustrating the agency of insects in producing galls and excrescences. The large and well-arranged collection of species belonging to the order Hymenoptera, which represent a portion of the entomological labours of Mr. F. Smith, have an interest to the apiarian as well as to the gardener, for there are many species the latter knows, or ought to know full well, since they belong either to his friends or his foes, and Mr. Capper's small educational collection of transformations is also good. The small department devoted to silk-producing species attracts lady visitors. Here Dr. Wailly's exhibit takes the first rank, following which are the specimens shown by Lady Nevill, Mr. P. Bannister, and M. Bourdier. It is disappointing to perceive that Messrs. Neighbour & Sons are, so far as I noticed, the sole representatives of apiarians; but their wives and apparatus drew some notice, especially as there were two cases of live bees. Also I saw persons inspecting curiously a cage containing caterpillars of the Cream-spot Tiger (*Arctia villica*), and I at first thought they were feeding on Cabbage, and that we had here an instance of a new enemy to the kitchen garden; but a closer examination proved that the leaves were those of the Dock, and their withered condition suggested that the caterpillars were thankful for small mercies. A choice and curious object that some people missed was the impression of a butterfly's wing brought from a slate quarry in Oxfordshire, where it was found in the colliery strata. Resisting the fascinations of an exhibition of performing seas, which had appropriately a place in the gallery, I left in the hope that this Exhibition will have numerous successors, and that Mr. Carington will be spared to take an active part in organising them.

EXHIBITION ROSE POINTS.

THE following notes were written for a Rose committee schedule, and the publication may be useful in guiding young exhibitors and instructing the public:—

The Committee of the — Rose Society will feel obliged by the Judges making their awards as much as possible in accordance with given points of excellence, which they have laid down under four heads for the guidance of exhibitors as well as the visitor. Classes are *bad*, *medium*, *good*, and *extra good*.

Bad flowers are all small-petalled flowers less than 2 inches in diameter, overblown and coarse, thin and showing an eye, not symmetrical or one-sided, badly quartered, hollow, with ragged outline, and all with stained and damaged petals.

Medium, or *one-point* flowers, are those just admissible within the exhibition pale. They are usually defective in one essential to a good flower, as large and symmetrical but too flat or rough; of good shape, substance, and colour, but small; again, with the three essential S's—shape, size, and substance, but dull and poor in colour.

Good, or *two-point* flowers, are those remarkable for fine circular outline, symmetrical and full centres, good size, clear bright colour, with large, regular, and stiff petals. Baronne de Rothschild is a fair type for a good exhibition Rose.

Extra good, or *three-point* flowers, are those possessing the above qualities in an extra degree of perfection. Grand high-centred flowers, very large and circular, with beautifully arranged or imbricated petals of great substance and brilliancy.

It should be borne in mind that the awards are given for the finest specimens of floricultural skill more than for mere novelty or rarity.—H. C.

HYACINTHS AT COOMBE AND CHELSEA.

DURING former years it has been the custom of Messrs. Veitch to arrange a grand display of Hyacinths, Tulips, &c., in the nursery at Chelsea; but this year neither the Hyacinths in the home nursery nor the contributions to the shows at South Kensington and Regent's Park have been of the usual high order of excellence for which the firm has become famed. Nor is this wholly, or indeed mainly, the result of the "bad season" for bulbs in Holland last year. That that circumstance has had a direct influence in contributing to the general low standard of this year's flowers may be admitted; yet in spite of that fundamental drawback the Messrs. Veitch have grown many grand Hyacinths this year which have not been brought before the English public in the usual manner. The success of the firm has been so signal in Hyacinth culture, and the honours they have won at home so numerous and conspicuous, that they have this year kept in reserve all the finest spikes for staging at the great International Exhibition which opens

at Ghent on the 31st inst. The plants selected for the great Continental gathering were retarded and retained in the nursery at Coombe Wood, and from thence were transmitted to Ghent on the 27th inst. Having inspected the plants previous to their departure we can testify to their great excellence; some of the spikes being as fine as any that have been seen during previous years; while those arranged at Chelsea are neither so numerous nor so good as usual.

No better opportunity can be afforded of forming an estimate of the merits of the varieties than when they are seen in quantity and cultivated in the best manner of which the bulbs are capable. Even selecting from those varieties staged at exhibitions is not an unfailing test of excellence, and for this reason—that some varieties are exceptionally good during a certain year, while the year following they are of little worth. Again, there are varieties which give about one grand spike out of six bulbs grown, the remaining five being of very moderate merit. As an example, the fine rich variety *Vurbaack*, which is so striking when well grown, is the reverse of being a certain and reliable variety. In purchasing one bulb of it there are five chances to one against its producing a good spike.

This matter is of such practical importance to purchasers that the following varieties are selected, not because they are super-excellent this year, but because they are constant—that is, good every year and reliable:—

Reds.—Charles Dickens, Emmeline, Fabiola, Gigantea, Ornement de la Nature, Cosmos, Lady Palmerston, Macaulay, Prince Albert Victor, Princess Clothilde, Princess Helena, and Von Schiller. The first six named are pale rosy pink in colour, the others darker and richer. The spikes are uniformly good, but if one is more constantly superior than the rest it is Von Schiller. A new red, *Meteor*, is the richest in colour of all.

Whites.—La Grandesse, Grandeur à Merveille, Madame Vander Hoop, Baroness Van Tuyl, Miss Nightingale, Alba Maxima, Snowball, Paix de l'Europe, La Franchise, Alba Superbissima, Elfride, and Mont Blanc. Perhaps the finest of the twelve is La Grandesse, but the three old favourites named immediately after it are exceptionally fine at Coombe.

Blues.—Grand Lilas, Princess Mary of Cambridge, Blondin, Lord Derby, as light blues; and as darker flowers Charles Dickens, King of the Blues, Baron Van Tuyl, Marie, and General Havelock; lilac or mauve, De Candolle, Haydn, and Sir Henry Havelock. The finest in this section is undoubtedly King of the Blues; it is one of the most constant Hyacinths in cultivation, but in this respect scarcely excels Charles Dickens and Baron Van Tuyl, for the trio are represented by spikes 9 inches in length and more than that in circumference. King of the Blues is, however, much the richer of the three. Two new blues highly promising are Grand Maître, tall spike, reflexed bells, and Queen of the Blues, a seedling from King of the Blues, bright blue, fine bells and symmetrical spike.

Yellows.—The three most reliable are Bird of Paradise, Duc de Malakoff, and Ida. The best blacks are the two new varieties—Masterpiece, glossy and very symmetrical; and King of the Blacks, a stately towering spike of fine black bells.

The above are single varieties, which are the most valuable both for decorative and exhibition purposes: the only few doubles of note being the following:—Koh-i-noor and Lord Wellington, reds; La Tour d'Auvergne (early) white; and Blocksberg, Garrick, Laurens Koster, and Van Speyk, blues.

The varieties above named are sufficient for any purpose, having one or several bulbs of each variety. For the information of smaller cultivators the following (a baker's dozen), are chosen for their constancy and intrinsic excellence irrespective of cost. A few of them are rather high-priced, but the majority are more plentiful and consequently cheap. *Reds.*—Von Schiller, Macaulay, Gigantea, and Fabiola. *Whites.*—La Grandesse, Grandeur à Merveille, Baroness Van Tuyl, and Madame Van der Hoop. *Blues.*—King of the Blues, Grand Lilas, Charles Dickens, and Baron Van Tuyl. *Yellow.*—Bird of Paradise.

TULIPS.—These are arranged at Chelsea, and very fine they are—dwarf in habit, regular in height, and bright in colour. The following are the more striking varieties:—Queen Victoria, pure white flaked with crimson and tinted with violet, very attractive; Bride of Haarlem, white heavily feathered with crimson; Fabiola, purplish violet and white; Golden Standard, scarlet and yellow, very gay; Joost Van Vondel, rosy crimson pencilled with white; Cottage Maid, rosy pink shaded white; Proserpine, rosy crimson, fine; Cramoisis superbe, cerise, tinted rose, distinct and beautiful; Pottebakker, white; Pottebakker,

yellow; Chrysolora, yellow; Keyzers Kroon, scarlet and yellow; and Vermilion Brilliant, splendid vermilion scarlet. The varieties named are valuable alike for exhibition and home decoration. They are all single. A few good doubles are La Candeur, white; Imperator Bubrorum, crimson scarlet; Tournesol, red and yellow; Yellow Tournesol, and Duke of York, white and dark rose.

The condition of the Hyacinths, Tulips, and Narcissuses reflects much credit on Mr. Hills, the grower, and the excellent order of the Coombe Wood Nursery generally does honour to Messrs. Veitch as proprietors and Mr. Dartnall as manager.

PRUNING PEAR TREES.

THE following remarks are suggested by the letter of "J. W."—It seems to me that there are two ways of managing Pear trees—art and nature, according to the position for which they are required. If you manage them by art you prune sharply, and at the same time root-prune occasionally, so as to preserve a just balance between the tree and its roots. This system is suitable for small gardens where space is an object, and where it is desired to grow many varieties. It is also necessary for a dressed garden where Pear trees in shapely forms are required on the sides of walks. But if space is no object, and uniformity of shape is immaterial, then by all means leave the trees to Nature, after three or four years' pruning, to form their heads. At ten years old they will be double the size of the annually pruned trees, and will bear much larger crops, though the individual fruit may not be quite so large. This last is no doubt the more profitable system.

There is one point which "J. W." has not gone into. He notices the amount of buds at the end of the shoots. But is not this a question of variety? Some Pears seem to throw out blossoms at the end of the shoots, and according to the established mode of pruning are consequently often barren (Josephine de Malines is a case in point), whereas others break out with tolerable regularity throughout the whole length of the branch. It seems to me that we have yet much to learn in this respect. Each family of Pears, if I may so call it, requires a special mode of pruning adapted to the peculiarities of its growth, whereas even the professed pruners apply the same measure to all.

Can any of your correspondents say anything about the Northern Spy (American) Apple? I have had two specimen trees for about ten years, one a cordon, the other an espalier, but neither of them has ever favoured me with a blossom.—A COUNTRY PARSON.

ANTS.

In the number of your Journal dated March 7th, under the heading "Sparmannia—Ants," it is stated in answer to the inquiry "Are the small black ants wrong in a conservatory?" "No, they are enemies of aphides."

Having for many years studied the manners and customs of ants, well designated by the inspired naturalist "a little people but exceeding wise," will you allow me to suggest that they cannot be said to be the enemies of aphides? On the contrary, these latter the ants cherish and protect, and from them derive the sweet secretion called honeydew, which serves them as wholesome nutriment; and in order to induce them to yield it for their benefit they cause their antennæ to vibrate rapidly over their abdomen, and this is the way the ants milk their cows, as the aphides are popularly called. In fact the aphid secretion forms the staple food of some species of ants, noticeably the common yellow ant, *Formica flava*, whose little hillocks are so common on our pasture lands. They even breed their cows. Last year I opened a nest in the early spring and found a chamber crowded with little black and brown shining oval bodies, which were being anxiously watched over by the workers. I kept them for some little time, and was much interested to find that they were eggs, or more correctly speaking, the nymphal forms of the aphid, since they produced ant cows of two colours.

When ants visit plants infested with aphides it is that they may secure their necessary sustenance; should they remove them it is that they may carry them to their formicarium, not for their destruction but for their preservation, in order that they may furnish nutriment from time to time for themselves and the young brood. It has been recorded that M. Duveau has seen an ant in the act of tearing and devouring an aphid, but such conduct is certainly quite exceptional. P. Huber

and A. Forel, who have faithfully chronicled their personal observations of the life history of ants, have never observed them injure an aphid. A careful observer cannot but be struck with the marked attention, assiduous care, and unflinching affection they bestow upon what to them is valuable property. I shall quite expect to learn that others can corroborate my own pleasant experience.—W. FARREN WHITE, *Vicar of Stonehouse*.

GHEENT.

BEFORE the next issue of this Journal a great gathering of horticulturists will have met in the "Flower City." Pleasant meetings and friendly greetings will have occurred between English and Continental nurserymen, and mayhap a few British gardeners may have found the opportunity of spending a few days in Belgium for the first time. We hope this may be so, for sure we are that no intelligent and observant gardener can visit the thrifty kingdom referred to, and inspect the nurseries with which Ghent abounds, without deriving many hints that would be of lasting benefit both to himself and those employing him. To the professional horticulturists of Britain the nurseries and gardens of Ghent are as familiar as those in their own country; but to the stranger—and it is to be hoped that there are always fresh visitors to every Belgian horticultural exhibition—even the briefest of brief sketches to some of the nurseries of Ghent will be acceptable.

A first glance at Ghent does not in any way denote that it is a city of flowers, for there are few, very few, flowers to be seen, even in the market. Neither are the nurseries remarkable for "flowers," always excepting Azaleas and Camellias; but for Palms, Ferns, and ornamental-foliaged plants they are probably unequalled. To attempt to sketch a route from nursery to nursery would result in failure; for the narrow twisting streets, the threading canals, the multitude of bridges, are far too numerous and too much alike to be specially referred to as landmarks for the guidance of any wandering pilgrim visiting the city for the first time. The whole town is quaint and its streets are perplexing; yet a conspicuous building in one place and a curious image in another soon become useful "guide posts," nearly as reliable and much more agreeable than the noisy, ubiquitous, persistent commissionaires who, bloused and badged, pounce on every promising stranger and make the most of him.

On arriving at Ghent, or, indeed, any other Continental town of similar size, it is important that the visitor have a clear idea of his destination, whether it is an hotel or a nursery, and go there direct and as speedily as possible. When once located the custom is such as to make him feel "at home," and all necessary information will be readily imparted, and his future becomes comparatively easy. Wherever he goes horticulturally he will find a frank masonic-like welcome await him, and will receive such attention as will almost certainly make him desire to go again. This is the happy custom of the officials of both large and small establishments. Among the places to be visited the first will probably be

VAN HOUTTE'S.—Not only is this the largest of the Ghent nurseries, but it is situated in a district where other notable nurseries abound. Van Houtte's is a gigantic establishment differing from most others because of the varied nature of its contents. The glass structures are more numerous than ornate, and the grounds are very extensive. Not a little but much of almost everything is here. It is a world-famed establishment—a wonderful nursery established by a wonderful man.

VERSCHAFFELT'S.—This nursery almost adjoins Van Houtte's. It is compact and crowded with plants of great value—Palms, Ferns, Cycads, &c., and is superintended by a master (M. Nuytens Verschaffelt), not of horticulture alone, but, what makes a visit agreeable, a master of the English language.

DE SMET'S.—This also is a compact nursery, differing from some others chiefly on account of its unique collection of curious plants—Agaves, Cacti, Dasyliirions, Yuccas, Beaucarneas, &c. It also contains Palms, Orchids, and Azaleas, besides hardy ornamental evergreens. About twenty houses are well stocked with plants, and the place is highly worthy of a visit.

DALLIÈRE'S.—Less than a mile from the trio of nurseries named is this compact, yet extensive and excellent establishment. Long rows of span-roofed houses are packed with small plants of Camellias and Azaleas. Many thousands of these plants are manufactured here, and their condition reflects much credit on the youthful manager, M. Adolphe de Meyer.

The large house is somewhat novel in its arrangement: the pathways being arranged in a carving serpentine manner that brings all the more notable plants of Palms, Cycads, &c., into close contact with the visitor. It is evidently a well-managed nursery and should not be overlooked.

PYNAERT-VAN GHEENT'S.—This is nearer the city. It is a long and narrow establishment enclosed with canals or nearly so, and has at its head one of the most genial and accomplished of Belgian horticulturists. At the outside of the houses are Bays, Yuccas, &c. In the grounds are hardy Azaleas, Magnolias, Rhododendrons, &c., and in the houses all sorts of plants which pertain to the industry of the country. The place and its owner are both highly worthy of acquaintance.

VERVAENE.—This is still nearer the city. It is a comparatively small nursery, but contains much that is choice, especially in Azaleas under glass, and Biotas and ornamental evergreens in the open air. Not only are new and choice Azaleas to be seen here, but dexterous manipulation is practised in grafting older plants; the fine umbrella-shaped heads being formed of different varieties, the colours being arranged with geometrical precision. It is an excellent type of one of the smaller of the Ghent nurseries, and its outlines may stand for about 150 others.

LINDEN'S.—This great establishment is quite in the town. A few Conifers in the enclosure command attention, but the fame of the nursery consists in its large and very numerous glass structures and their contents. The houses are richly furnished with plants large and small, beautiful and rare. Palms, Ferns, and ornamental-foliaged plants are grown by thousands, and many specimens remarkable for their novelty and beauty are arranged in the houses. It is a wonderful nursery—an immense manufactory of those plants, Palms especially, for which it is famed.

VAN GHEENT'S.—This renowned establishment is in another direction. In addition to containing large and varied collections of plants under glass, the nursery is in high repute for Conifers, Rhododendrons, Hollies, and other evergreens, Roses, and hardy ornamental trees and shrubs, all of which are grown in large numbers and of excellent quality. It is one of the most important of the Ghent nurseries, and commands the patronage of a large number of visitors.

Other nurseries are worthy of being found out and visited—such as Spae's, Connick's, Gaselle's, Boelen's, Boddaert's, Baumann's, Vuysteke's, Bruylant's, Lubber's, Aper's, Cornelissen's, Van Riet's, Saegher's, Van der Swaelmen's, De Cock's, Van der Meulen's, and some others which, though individually small, yet collectively exert great influence on the industry of horticulture, and contribute in no small degree to its reputation and prosperity in the city where it is practised with such thrift and skill.

BRISTOL AND CLIFTON HORTICULTURAL SOCIETY'S SPRING SHOW.—MARCH 20TH AND 21ST.

EXHIBITIONS of spring flowers are amongst the most enjoyable of floral gatherings. They are worthy of encouragement, not only because of the intrinsic beauty of the flowers composing them, but also because such flowers are within the means of a large number of cultivators. Local horticultural societies, by giving an impetus to the culture of such plants as Hyacinths and other Dutch bulbs, Lilies, Spiraeas, Azaleas, greenhouse Ferns, &c., do much to popularise floriculture by enlisting the sympathies of a large class of the community whose conveniences are not adapted to the culture of valuable exotics and gigantic specimen plants.

One of the first of the provincial spring shows of the year was held in the Victoria Rooms, Clifton, on the above date, and was, we are informed, an excellent one; indeed, according to the *Bristol Daily Post* "very few spring shows in the provinces could boast of a better collection of plants and flowers, and the Orchids, which have always proved a special feature of the local Society's spring fête, were conspicuous by their richness and beauty." Large collections of ornamental-foliaged plants from Messrs. Tagart, Briant, Hoskins, and Saunders formed central groups, around which were arranged the real attractions of the Show—the bulbs. Hyacinths, as is generally the case, were below the average, but Tulips and Narcissuses were excellent. The silver cup given by the Treasurer, Walter Derham, Esq., for twenty-four Hyacinths and twelve pots of Tulips, was won by Mr. Perry, gardener to J. W. Miles, Esq., who was also awarded the silver Banksian medal given by the Royal Horticultural Society for twelve Hyacinths. The bronze medal of the same Society for the best-arranged vase of flowers for table decoration was won by Mr. M. Hoskins.

A noticeable feature of the Show, and a gratifying one, was the large number of special prizes offered. These numbered more

than thirty, and were given by the gentry of the neighbourhood for collections of greenhouse plants, Asaleas, Ferns, Hyacinths, and other Dutch bulbs, Cyclamens, Primulas, Camerarias, Mignonettes, Roses and bouquets. Prizes were also awarded for dishes of Apples and Pears. Messrs. Garraway contributed collections of Rhododendrons, Hyacinths, &c., also their new white Mignonette. Messrs. Maule & Son and Mr. Gold also staged valuable collections, and Mr. Hooper, Bath, sent some fine varieties of Fancies. The Show was well managed by Mr. Webley, the Secretary, and an active Committee, and was attended by a considerable number of visitors.

ESCALLONIA MACRANTHA.

I AM not aware of the dimensions to which the *Escallonia macrantha* usually grows, but the one that is in my garden at Sorrento Terrace, Daltry, appears to me to be far larger than any that I have seen elsewhere.

This shrub was planted in the spring of 1864. It was then a very small plant. Its trunk (or rather one of them, for there are three) measures now 14 inches in circumference, whilst the branches have a spread of 16 feet in width and 11 feet in height. To these dimensions it is confined by being annually clipped with the shears, the position of the house obliging it to be thus limited; but were it not so it would be difficult to tell to what distance and height it might have now extended, for the yearling shoots are always upwards of 2 feet in length. The aspect of the garden is south-south-west, the soil very porous and dry, and the elevation 90 feet about the sea, immediately bordering upon Killinay Bay. This *Escallonia* begins flowering about the middle of March, and continues in beauty until the middle of December, during which time it produces thousands of blossoms. — JOLLIFFE TUFNELL, F.R.C.S.S., Dublin.

WORK FOR THE WEEK.

KITCHEN GARDEN.

GROUND intended to be planted with Globe Artichokes should be prepared by trenching, if not already done, and enriching with manure. They prefer a moderately light soil and moist, but freed from stagnant water. An open situation should be chosen, yet sheltered from winds. The mulching of litter about the crowns for protection should now be removed and replaced with a dressing of short manure, which is essential to the production of large heads. The finest heads are borne by young plants planted in rich soil and liberally supplied with liquid manure; indeed, moisture must abound at the roots if large and tender heads are desired. Some cultivators grow the plants upon the same ground for a number of years without change. We only keep them two years—i.e., at this time or early in April we take up the plantation that has been planted two years, divide the roots, choosing pieces with three strong offsets, or at most four, retaining a portion of the old roots, and plant rather deeply in rows 4 feet apart, allowing the same distance between the plants. These afford a moderate supply of heads in late summer, succeeding those not disturbed in the year-old bed, which produce an abundance of heads. In old plantations it is necessary to thin the suckers, leaving six or eight of the strongest to each stool. If only planted 3 feet or less apart three or four of the strongest suckers only should be retained. Rhubarb intended for forcing next winter must not be gathered from this season, but be allowed to grow unrestricted, both to secure vigour and early ripening. Asparagus for forcing must not have the heads cut this season; but Seakale, unless the crowns are very small, should be cut, in order to prevent seeding. Go over the plantation after growth has commenced, with a view to the reduction of the number of crowns, removing the smaller growths. Proceed with the planting-out of autumn-sown Cauliflowers, Lettuces, and Cabbages; complete also the planting-out of Tripoli Onions as soon as possible. Another sowing of Peas and Broad Beans to be made, earthing-up and sticking advancing crops of the former. Dusting crops whilst damp with soot or wood ashes, both being good fertilisers, is a certain method of warding-off attacks of sparrows and slugs. Make a sowing of Round Spinach every fortnight. Turnips do not last long fit for use early in the season, therefore make successional sowings frequently. Sow Cabbage for autumn use—Carter's Heartwell, Wheeler's Cocoa Nut, Hill's Incomparable, and Nonpareil Improved are capital kinds; Little Pixie is also dwarf and delicious. Also sow Broccoli—Snow's Winter, Pensance Early White, Cooling's Matchless, Veitch's Spring White, Leamington, Lauder's Goshen, Sutton's Perfection, and Model are excellent kinds, coming-in in succession. Only moderately fertile soil should be employed for seed-sowing of the Brassica tribe, the seedlings being more sturdy and better rooted than when grown in very rich soil, and are more safely transplanted.

Forcing Department.—Make another sowing of French Beans in a heated pit or frame over a gentle hotbed, and at the same time

an extensive sowing in a ground vinery. We place three rows in a span-roofed one 4 feet wide, 15 inches deep at the side, and 2 feet in the centre to the ridge, a row in the middle of Canadian Wonder, and rows 9 inches from the sides of Osborn's Forcing. These succeed those sown in heat, and come in just before those sown in the open ground.

FLOWER GARDEN.

Plant Gladioli both of the *Ramosus* and *Gandavensis* section. They should have moderately rich light deep soil and an open situation—better if sheltered from winds. We plant the corns 4 inches deep, and in damp soil surround them with a little sharp sand. Gladioluses are so highly ornamental and useful for cutting that they should be extensively planted in mixed borders, and corns are now so cheap that there is no need to be without a supply of these fine late summer flowers. Patches of half a dozen to a dozen plants in shrubby borders enliven them immensely. Seed of Polyanthus and Auriculas sow in boxes, placing them in a cold frame, and keeping the soil moist. Sow also Pansy seed, which will produce plants that will flower finely in late summer. If beds of these and of Pinks were not made in autumn plant out at once. If the plants are in pots be careful not to disturb the ball, and if from the open ground retain the roots uninjured. The frost not infrequently disturbs the soil by lifting the plants of Pansies and Pinks. Press them into their places, and give a top-dressing of rich compost all over the bed. Plant-out Carnations from pots or the open ground. The Glove varieties should be grown extensively for cutting from, indeed beds of these are less seen in flower gardens than their merits deserve. A few select Gloves are Prince Arthur, Hindoo, Ambassador, Albert, and Telegram in crimson or purple-crimson; Dazzle, Sentinel, and Géant des Batailles in scarlet; Christine, rose; Maiden's Blush, Bride, Queen of Whites, King of Yellows, with Snowflake and the old Criméon. Pinks worth growing in quantity for cutting are Anne Boleyn, Lady Blanche, Coccinea, Lord Lyons, Rubens, and Mrs. Pettifer. The three first are good for forcing. Complete the planting of Anemones and Ranunculuses. Such as were planted in autumn will be above ground, and must have the soil firmed about them. Plant Hollyhocks in deep rich soil, and mulch round each plant with short litter. A dozen and a half good varieties are James Whitton, Invincible, John Tweedie, Mrs. Downie, Mrs. Bruce, B. Todd, Mrs. F. H. Douglas, Mrs. P. Bruce, Hugh Smith, Andrew Jamieson, Archbishop, Miss Young, William Fowler, Andrew Goodfellow, Lord Stanley, Octoroon, Model, Ida, and Lady Hume Campbell. East Lothian Stocks wintered three in a pot may now be planted-out in rich soil in an open yet sheltered situation, and they will bloom finely through the summer. Divide the old roots of Dahlias, leaving a bud to each; pot each division singly, and grow on slowly until planting time. They do much better in this way than placing them in heat to obtain stock. Sow seed of *Helichrysum* in gentle heat; prick-off the seedlings in boxes or in a frame, keeping close until established, growing the plants on and having them strong by the early part of May. Their flowers are very showy, and are useful for drying. A good batch of the ornamental Grasses should be sown shortly; they are indispensable for mixing with flowers in vases, &c. Some of the most useful are *Agrostis argentea*, *nebulosa*, and *pulchella*; *Briza gracilis*, *B. maxima*, *Bromus briziformis*, *Eragrostis elegans*, *Hordeum jubatum*, *Lagurus ovatus*, *Lasiagrostis argentea*, *Piptatherum Thomasi*, and *Pennisetum setosum*. Tropæolums of the *Lobbianum* vars. are fine for trellises, rooteries, or rockwork, and should be sown now, potting-off the plants when they are showing the second leaves. They should be strong and well hardened-off by the end of May for planting. If planted a foot apart in a line and supported with sticks they make a capital floral screen.

PLEASURE GROUNDS.

As a rule we do not advocate the mixing of trees and flowers yet nevertheless we advise the planting of such herbaceous plants and Grasses which from their stateliness, boldness, grace, or elegance are in good keeping with trees and shrubs. Such fine flowering plants as *Yucca gloriosa* and *recurva*, *Anemone japonica* and var. *alba*, *Tritoma*, &c.; or of Grasses, *Gynurium argenteum*, *Erianthus Ravennae*, *Phalaris elegantissima*, *Eulalia japonica*, &c.; Bamboos, *Aralia Sieboldi*, *Gunneras*, and *Rheums nobile* and officinale. There are few pleasure grounds in which suitable places could not be found for these and plants of similar character. Damp ground will afford a home for the different varieties of herbaceous Spiræas, and low-lying places may be made quite picturesque by the addition of the herbaceous *Lobelias* and *Agapanthus*. Lawns seldom receive the attention necessary to keep in check weeds of a perennial character, such as Daisies, Dandelion, Plantain, and the coarser Grasses. Much may be done by grubbing up with a knife—a tedious operation but a certain one for Daisies, whilst Dandelion and Plantain are speedily destroyed by placing in the centre of each plant a little sulphuric acid. A blacking bottle with a wire round the neck to carry it by, and a notched stick to apply the vitriol with to the plant, are all that are wanted except care, for the acid will burn everything it comes in contact with, and must not be entrusted to a mischievous boy or careless person. Walks should be kept well swept and rolled, and the grass likewise, going over it with the machine when

necessary, as nothing injures the grass so much as allowing it to grow long and then cutting it very short, which encourages the growth of weeds and coarser grasses. The edgings of the walks must be put in order for the season.

FRUIT HOUSES.

Pines.—Those started early in the year will have bloomed or be near that state. After flowering an occasional sprinkling overhead at closing time will be highly conducive to the health of the plants and swelling of the fruit, but avoid wetting those that are in flower. Admit air carefully and early, so as to draw off the moisture from the leaves before the sun acts powerfully upon them. A very small amount of ventilation is necessary, and the temperature must not be lowered by admitting air too freely. It is well in houses having large squares of glass to employ a slight shading for a couple of hours or so during the hottest part of the day until the leaves become inured to the sun's influence. Except, however, in special cases shading is best dispensed with altogether. Air may be admitted at 80°, closing at 85°; let the temperature be 75° by day from fire heat and 70° at night, keeping the bottom heat steady at 80° to 90°. Do not water at stated times whether the plants require it or not, but when a plant becomes dry give liquid manure plentifully. Remove all the suckers as they appear except one to each plant. Continue the treatment before advised for successional plants.

Figs.—The earliest crop is swelling rapidly and will require careful attention to watering, especially in the case of trees in pots, which must be kept well supplied with liquid manure, for if they once lack water at the roots the fruit will in all probability fall when they swell for ripening. Top-dressings of rich compost are very beneficial. Apply the water a few degrees warmer than the mean temperature of the house. Do not increase the temperature until the fruit is fairly on the move, but keep the heat steady at 65° to 60° at night, 10° to 15° higher by day, closing early. Red spider will put in an appearance all the sooner if the atmosphere be at all dry; therefore syringe the trees twice a day, damping the floors, walls, &c., with liquid manure. Ventilate carefully. The weather having been for some time dull attention must be given to early air-giving upon the setting-in of bright weather with a view to prevent the young leaves scorching. Trees planted out will be making rapid progress. Attend to stopping and thinning the shoots, and watering and mulching the borders.

Strawberries in Pots.—The best means of keeping down red spider is to keep the plants well supplied with water. They should be examined twice a day, and in bright weather three times, and any wanting water must be supplied liberally, giving liquid manure two or three times a week when the fruit is swelling. There is nothing like slow but progressive growth for Strawberries. Hard forcing does not suit such as Dr. Hogg and British Queen, which are the best late varieties. Sir Joseph Paxton and President are excellent for pot culture, but they will not bear forcing like Vicomtesse Hélicart de Thury and Keens' Seedling. We grow Strawberries in all our fruit houses, and have two shelves in each house; one shelf is occupied with an early variety and the other with a late one, so that there is no break in the succession. In the later batches the trusses are coming very strong, and with them green aphid, which must be kept under by fumigation.

Orchard House.—Dull damp weather is not favourable to the setting of the fruit. Apricots especially do not set well in such weather, and air should be admitted in abundance, attending to it early in the day, and closing early in the afternoon, leaving on, however, a little air at night whenever the state of the weather permits, as a stagnant atmosphere is fatal to the setting of the fruit. In the case of heated structures the heat may be turned on early in the morning, which will admit of freer ventilation, but we do not advise a higher temperature to be maintained than 45° to 50° by artificial means. It is desirable to go over the blossom of the Apricot, Peach, and Cherry with a camel-hair brush, applying the pollen of the anthers to the stigmas of the flowers. Early closing will be necessary with a view to husband the sun heat, and prevent the temperature falling too low during the night. Syringing must be discontinued until the fruit is well set, but the borders must be watered if the trees are planted out, whilst those in pots should be kept well watered. Neglect in that respect may cause the flowers to drop without setting.

PLANT HOUSES.

Greenhouse.—*Isolepis gracilis* is a very accommodating plant, and very useful. Divide now, and pot off singly. A plant in a 5 or 6-inch pot will divide in many pieces. It is graceful for the margin of shallow basins filled with water in summer outdoors. Dependence is chiefly placed upon fine foliage and variegated plants for decorating halls, &c., in summer. They should not have larger pots than is necessary to maintain them in a healthy state, as the pots are often required to fit into vases. Young healthy well-grown plants only are available, and to keep them in small pots liquid manure should be given so as to render the pot room as small as possible. *Acacia lophantha*, *Aralia crassifolia*, *A. trifoliata*, *A. Sieboldi* variegata, *Aspidistra lurida* variegata, *Bambusa Fortunei* variegata, *Eurya latifolia* variegata, *Fartugium grande*, *Ficus elastica*, *Grevillea robusta*, *G. longifolia*, *Lomatia*

leptophylla, *L. ferruginea*, *Rhopala corcovadensis*, *R. elegans*, *Yucca filamentosa* variegata, *Y. aloifolia* variegata, and *Y. quadricolor* are all suitable, and do well in equal parts of turfy loam and sandy peat, with a free admixture of silver sand. Palms also, such as *Areca Baueri*, *A. rubra*, *Brahea filamentosa*, *Chamserops excolsa*, *Phoenix reclinata*, *Rhapis flabelliformis*, and *Seaforthia elegans* are very suitable for house decoration. Cut back *Epacris* which have done flowering. They may be cut to within an inch or two of where they were shortened to last season. A slight increase of temperature and sprinkling overhead will induce free growth, which, however, is not desirable unless the plants are required for early flowering. *Camellias* that bloomed early will now be pushing growth strongly, and should be encouraged with warmth and abundant moisture both at the roots and overhead, shading from bright sun. *Acacias*, *Cytisuses*, &c., out of bloom should be cut back, and have growth encouraged by sprinkling and keeping the plants rather close. *Azaleas* are pushing freely, and must have copious supplies of water. Any plants that it may be desirable to retard for late bloom should be placed in a cool house with a northern aspect. Heaths for summer flowering will require to be gone over, training the flowering shoots in the position required when in bloom. Use as few stakes as possible—no more than necessary to give the required shape. Those plants advancing for bloom will require more water than when the roots are less active. *Daphne indica* is a great favourite, and not often met with in such quantity as its deliciously scented flowers merit, besides it is often found in an unsatisfactory state. This mainly arises from its not receiving encouragement when making new growth. An increase of heat and moisture is necessary until the flower buds are formed, affording weak liquid manure, which materially assists the growth. Keep a strict look-out for aphides upon *Pelargoniums*, fumigating whenever one insect is seen. Those plants throwing up the trusses for flowering will be benefited by liquid manure, freer watering being now required than earlier in the season. Attend to training the shoots. Plants for late flowering stop, and if in small pots shift into larger. *Fuchsias* shift into larger pots, stopping the shoots until the plants are well furnished. Syringe in the afternoon, encouraging growth by applying liquid manure and a moist but well ventilated atmosphere, and plenty of light. *Calceolarias* feed with liquid manure, and fumigate to keep green fly under. *Rhododendrons* of the *jasmiflorum* type will be advancing for flowering, and should be well supplied with water; in fact, all plants advancing for flowering or making growth should be kept well watered. *Primulas verticillata*, *cortusoides*, *amena*, &c., are the better for having liquid manure when showing the flower trusses. *Erythras* are fine for summer flowering. They should be cut-in to within a few eyes of the base of the shoots, be turned out of the pots, disrooted, and started in gentle moist heat. It is essential that they be kept near the glass, and frequently syringed to keep down red spider. Remove the lights from *Violets* in frames, having the plants well hardened off preparatory to planting. *Spiræas*, *Lily of the Valley*, and other forced plants should after flowering be kept in a light airy house, so as to have them well hardened off by the time the weather is favourable for planting them out. *Deutzias* after flowering should be cut well back, and be placed in heat to encourage growth. *Hyacinths*, *Narcissus*, &c., after flowering place in frames, and water and ventilate freely. Though not available for growing in pots again they are suitable for borders.

TRADE CATALOGUE RECEIVED.

The Thames Bank Iron Company.—*Illustrated Catalogue of Boilers, Pipes, Fittings, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (P. J. W.).—We do not know of a book more likely to suit your purpose than the "Cottage Gardener's Dictionary." It contains information on the propagation and culture of all popular plants, also on the cultivation of fruits and vegetables. (M. T. D.).—Mollison's "The New Practical Window Gardener."

PRUNING ROSES (Mrs. Cranford).—Prune the long shoots to the desired length, and the dormant eye near the bottom will swell forthwith and make much stronger growth than those would which are now so full of promise at the tops. If the shoots are at all crowded cut out the smaller when you shorten the others, so as to admit light and air to the centre of the plant, and thus add to its health and vigour.

STOPPING THE GROWTH OF PELARGONIUMS (Idem).—The tips of the leading shoots are nipped off to induce lateral or side shoots to grow, and

for no other purpose. When the blooms are set nipping would be a disfigurement and would serve no good purpose, for neither of those sections under which are included show and fancy varieties bloom more than once a year, while the zonals fairly merit the title of "perpetuals."

PRUNING ROSES (*A Lover of Rose Shows*).—I strongly recommend you not to prune Roses which were planted in March till at least a month from the time of planting, and then not to prune at all hard. The blooms will be a little late, but they will come in for any of the July shows. The Moss Roses must be pruned in April, at the time you cut the Teas; but very carefully and gently must you use the knife here. Almost as slight pruning is required for Moss Roses as for Teas and Noisettes.—WYLD SAVAGE.

CINERARIAS WITHERING (*Buckland*).—Probably they have the interior of the soil about the roots too dry.

ERRATUM.—In his letter (see page 200) on judging Roses Mr. Cant inadvertently wrote the name of Rev. Canon Hole instead of Rev. J. B. M. Camm. Mr. Cant's remarks were made in reference to the last-named rosarian.

DOUBLE PRIMROSE (*R. T.*).—It is the old Double Crimson, a rare variety on account of its delicate constitution. We think it can be obtained from Mr. Olibran, Oldfield Nurseries, Altrincham, and probably also from Mr. Ware of Tottenham and Mr. Parker of Tooting. It is increased by division.

DEUTZIA GRACILIS CULTURE (*St. Henore*).—Poverty of soil and drought are the probable causes of the weakly growth of your Deutzias. As the plants lose their blossom prune the old exhausted growth to 2 or 3 inches, water regularly, and keep them in the greenhouse or a garden frame till all danger from frost is at an end; then turn them out of the pots into an open sunny border thoroughly broken up and enriched with manure. Do not crowd them, but afford each plant ample space for the growth of root and branch. Keep down weeds, water well in dry weather, watch the progress of the growth, thinning all crowded shoots before they become long, and giving copious doses of sewage or other liquid manure if the progress of the shoots from which you will obtain flowers next season prove unsatisfactory. When growth ceases and the foliage is fallen the plants may be taken up, repotted, and placed in the greenhouse.

CULTURE OF MIGNONETTE IN POTS (*Idem*).—The plant nature of this old favourite has led to much slovenly culture. To have it in flower in mid-winter you must sow the seed from May till September; in May if you intend growing large specimens, and one, two, or three months later in proportion to the size of plants required. Little bushes may be had by sowing seed in August, draining the pots well and using a rich loam, keeping the pots altogether under glass or plunging them in coal ashes in the open air for a month or two, the latter method being generally preferable. When the pots are well filled with roots use liquid manure regularly, avoid crowding, and give the plants as much light and air as possible. You may have one plant or half a dozen in a 5-inch pot. We prefer single plants, nipping off the tips of the growth for a time to make bushy plants, and then letting the shoots come into flower.

PLANT FOR BACK VINERY WALL (*J. B.*).—No flowering plant answers so well for the back wall of a vinery as the Camellia. Fimbriata is a well-tried white sort, and Sarah Frost is a favourite pink variety. Camellias would also answer well for your shaded conservatory wall. A list of choice varieties was given in No. 885. *Hoya carnosa* answers well with us upon a shaded wall, and bears its charming flowers abundantly.

GRAPE VINE CULTURE (*A. L.*).—Syringe the Vines to encourage the buds to swell, but discontinue syringing when foliage is visible. One shoot only to be left on each spur, the tip to be nipped off at the second eye beyond the bunch, and not sooner, or you will have no Grapes. A pair of rods trained to each rafter is just one too many. At the end of the growing season when the leaves fall cut off the weaker rod, leaving only one to each Vine. If those which you retain are in a weakly unsatisfactory condition take up a young rod next season, keeping the old one to produce a little fruit, and afterwards cut it down.

ARRANGEMENT OF COLOURS IN FLOWER BEDS (*Idem*).—A central mass of one colour with an edging of another is decidedly in better taste than an alternating series of stripes.

HEAVIEST BUNCHES OF GRAPES (*W. H. N.*).—The heaviest bunches of white Grapes are Calabrian Raisin, weighing 26 lbs. 1 oz., grown by Mr. Curror, Eakbank, Dalketh, and Syrian, 25 lbs. 10 oz., grown by Mr. Dickson of Arkleton. These weights are recorded in the *Journal of Horticulture* for November 16th, 1875. The heaviest bunch of Black Grapes is Gros Guillaume, weighing 23 lbs. 2 oz., grown by Mr. Roberts, Charleville Forest, and recorded in the number for November 15th, 1877.

PRUNING YOUNG PEACH TREES (*An Old Subscriber*).—Prune them immediately, leaving the lower branches 18 inches long and upper branches about half that length.

GARLIC (*Bulls*).—We cannot enumerate its medicinal uses, you must refer to the Pharmacopœia, nor can we recommend any continental dealer in bulbs. Refer to the "Horticultural Directory."

ASPARAGUS (*W. S. F.*).—Connover's Colossal. It is a very fine variety.

BRESEE'S PROLIFIC POTATO (*F. J.*).—It is a pebble-shaped variety, some of the tubers being bluntly oval, and such have been selected and exhibited in the kidney classes. It is, however, usually exhibited as a round variety.

SCALE ON PLANTS (*R. M.*).—Your Feverfew was badly infested with thrips and scale. You did quite right in destroying it; neglect and want of cleanliness was the cause of its being so badly affected. Examine closely the whole of your other plants, sponge the foliage, branches, and stems with clean water, dip them two or three times in Fowler's insecticide, and practise sponging and syringing regularly in future.

EXTIRPATING WIREWORM (*B. H. Brookbank*).—Deep stirring of the soil in autumn and exposure to frost has been often recommended as a curative for wireworm, but we have no faith in it, having found the tough-coated little rogues as lively and abundant as ever in the following summer. We once had a piece of land badly infested, which we planted with Potatoes, and just as they were starting into growth a couple of men were set with garden trowels to take up every Potato, pick out and destroy the wireworms, and replant. The process, though tedious, was efficient, and we strongly advise you to forego your intention to sow Oats and to plant Potatoes instead. Lawes' grass manure at the rate of 5 cwt. per acre is what you require.

PAINT FOR INTERIOR OF STOVE (*D. L. Allerton*).—We know of no paint superior to that having white lead as its basis. A great advantage is

its smoothness, enabling it to be washed clean and expeditiously. Plant must not occupy the house until the smell of the paint is gone.

GLAZING WITHOUT PUTTY (*F. Bishop*).—If you buy our No. 872, published on the 18th of last December, you will find there full directions and an illustration. There is no drip caused by this mode of glazing.

LYVELLING (*A Regular Subscriber*).—We do not publish a book on the subject. We recommend you to buy London's "Self-Instruction for Young Gardeners;" it contains directions for levelling and laying-out gardens.

NAME OF FRUIT (*A. J. Lovelond*).—It is a noted Essex Apple called D'Arcy Spice or Baddow Pippin.

NAMES OF PLANTS (*Inquirer*).—1, *Cotyledon umbilicus*; 2, *Cereus flabelliformis*; 3, *Oytisus racemosa*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTURE OF CLOVERS AND GRASSES.

(Continued.)

Suckling Clover.—This has a yellow flower very like the trefoil, or hop clover as it is termed, but is altogether a distinct sort, being a perennial or permanent grass when so required. There are two varieties, a dwarf or wild sort, usually found on light sandy land and gravelly soils, and is indigenous to these soils on both pasture and arable land, and has a peculiar flower, perfectly round when in full bloom. It has in consequence been often termed by the local name of the mophead suckling. The other variety has a smaller flower, more open and yellower in colour when in full bloom, but the haulm or stem is strong and lengthy and very fine, and makes hay of the finest quality; but it is scarcely ever sown alone, and from our own experience we recommend its being sown with red clover instead of rye grass, as it does not compete with and injure the growth of red clover like rye grass; for although rye grass is often sown with the red clover for the purpose of making up for vacancies or deficiencies in the plant, yet our experience tells us that it is oftener the cause of failure of red clover. When sown together we have often seen where red clover has failed it has been only on that part of the field where rye grass seeds have accidentally fallen out of the hay given to sheep at the time of feeding-off the previous crop of roots. Suckling when sown with other clovers has all the advantages of rye grass without the disadvantages. Rye grass is often sown with clovers because it can be more quickly dried into hay than when the clovers are grown alone, and we have found the hay can be stacked three days earlier with rye grass mixed, and that when suckling is sown with either red or white clover the hay can be carted two days earlier. Suckling has another peculiarity, for when properly seeded and sown after the ring roller it is sure to take, has fewer enemies, and improves the feeding quality of any crop of which it forms a part. It is also a late grass, and comes into bloom about the same time as either red clover or white Dutch clover; and our favourite mixture is red clover or white clover 10 lbs. of seed, and of suckling 4 lbs. per acre; and when the white clover is mixed with suckling as it should be, and sown in alternate husbandry—that is, red and suckling one course, and white and suckling the next, it is almost certain to plant with regularity; in fact this is almost the only way that red clover can be depended upon to give a full crop upon light soils.

Cow Grass, or, as it is in fact, perennial red clover, is a very distinct sort from the broad or red clover, and varies so much in appearance and in its habit of growth that we think it quite a different species. Only one heavy crop in the year can be obtained, and it comes into cut from twelve to fourteen days later than the first cutting obtained from red clover; and it is well to sow suckling with this sort if on light soil, as the suckling will make a second crop. Cow grass makes a very coarse hay, and the only object of its growth on arable land has been for alternation with broad clover; still the quality of the hay is much improved when suckling is grown with it.

Yellow Clover or Trefoil, commonly termed hop clover, is the earliest to blossom of any variety, and used to be very often

mixed with red clover and rye grass; but as it comes into bloom before the red clover it is ill adapted for a mixture, and in our experience the only advantage of growing it at all is to grow it with rye grass and cut for hay very early, where the land is intended for a root crop afterwards.

Rye Grass is of several kinds, and is much used on hill farms in admixture with white or yellow clover, especially where intended for sheep-feeding only, and when required to hold over the seeds for feeding the second year the perennial rye grass is generally selected for the purpose, and affords abundance of pasturage. The ordinary sorts of rye grass, however, attract but little attention now, and not as they did formerly before the Italian rye grass came into use.

The *Italian Rye Grass* is a distinct variety compared with any of our old sorts, and has the peculiar advantage of early growth and quick succession when fed or cut; but the seed produced in this country soon loses its early habit of growth—probably the effect of soil and climate, and when a crop is desired for early uses it should always be obtained by the sowing of foreign seed from the south of France or Italy. Much of the imported seed is, however, foul with weed seeds, and ought to be carefully cleaned by the seedsmen before it is sent out for the farmers' use. This crop is now much in use upon the stock farms and in the hill countries where there are no water meadows; and by the growth of Italian grass manured with 2 cwt. of nitrate of soda per acre a crop will be obtained as early as that grown in the irrigated meadows, and far more proofy for sheep and cattle, with an excellent succession of after-grass during the summer, which will require a heavy stock to keep it down. In many cases this grass is only fed-off twice in the spring, the land being then ploughed and sown with roots of some sort. This grass when sown in either wheat or Lent corn produces fine crops in the autumn, and especially if the corn harvest happens to be early. We have on some occasions hurdled-off this crop three times between harvest and Christmas with forward stock with great advantage, and then fallow-ploughed the land in the winter to come in for other and more important and weighty crops, such as mangels, carrots, or Swedish turnips. This grass is sometimes laid down when near to farm premises for the purpose of irrigation by the drainage from the cattle yards, &c.; and in order to obtain a sufficient supply of water to carry and distribute the dung water it is well (and we are adopting the plan on several farms) to collect all the water from the spouted buildings and connect it by underground drains for that purpose.

Saintfoin is a most useful and permanent fodder plant when properly cultivated, laid down on clean land, and fed so as to prevent injury to the crowns or heads of the plants. It is usual to cultivate it on chalk soils or soils resting on chalk, and as the plants strike their roots very deep into the earth it will endure for many years. The seed of saintfoin being so much larger than clover seeds, requires to be drilled or sown after the plough in order that it may be more readily buried, for there is no seed more difficult to bury, because it is usually sown with the husk entire. It is, however, sometimes milled or freed from the husk, but it receives damage in the process unless done with great care, in which case many seeds will not vegetate when injured or crushed in the act of milling. Saintfoin is usually sown broadcast, and yellow trefoil sown with it to fill up for a hay crop the first year; but we prefer the yellow suckling to sow with the saintfoin, say 5 lbs. per acre, and not less than 4 bushels of saintfoin seed. This crop is usually only retained for about four or five years, but when it is required to be maintained for an indefinite period we prefer to drill the seed at 14 inches between the rows; the land may then be horse-hoed between the rows, and dragged and harrowed crossways. In this manner the crop may be kept quite clean, and when drilled for the purpose of being kept clean no suckling or trefoil should be sown with it. If, however, only four or five years' growth is required the suckling is first-rate, for it not only improves the hay by its fine quality, but it completely occupies the land between the saintfoin plants, and prevents the lop, and water grass, and other weeds from obtaining possession. The general management of this crop by feeding with sheep is very bad. The hungry ewes in the hill districts are often allowed in the autumn and early winter months to eat down the crowns of the plants, which destroys many of them and weakens the remainder. In this the crop becomes foul at the end of four years, and is then generally broken up; but in case it is required for permanency it is best fed by cattle, as they do not bite so close as sheep. This crop is much to be preferred to clover for horned cattle, especially for milch cows, for clover is often injurious, the animals becoming "hoven" or "blown," but this never occurs whilst feeding upon saintfoin. The hay derived from this crop, and especially when suckling is grown with it, is considered the most valuable of any, especially for farm horses, carriage or cab horses, &c., for which purpose it will always fetch the highest price. As saintfoin is usually sown in the Lent corn the barley or oats should be drilled at 12 inches between the rows. This gives a better chance for the young saintfoin plants to obtain strength. We, however, find that the plant takes best when drilled in a crop of wheat, if the wheat has been sown after a

turnip or other fallow crop; but the land should be well harrowed so as to obtain a sufficiency of loose mould to bury the seed properly.

The *Giant Saintfoin* is a distinct variety, and will grow luxuriantly upon the mixed soils of most districts; but it requires that the land should be in first-rate tilth and condition, and previously subsoiled, the subsoil plough being worked both lengthways and crossways. The steam cultivator is, however, best, and when the subsoil is effectually moved and stirred, but not turned up, the young plants succeed capitally, being enabled to drive their roots deep into the soil at the early stages of growth, and the habit of the plant being to root deeply this is the leading point in its cultivation. If, however, it is required to stand for a number of years it must be very carefully fed and cut, for the plant is not so hardy as our ordinary saintfoin, and should be treated with all the caution and care as stated to be requisite in the cultivation of the common sort. This variety is not so well adapted for hay, being coarser, yet when a mixture of suckling is grown with it the quality of the hay is very much improved.

WORK ON THE HOME FARM.

Horse Labour.—The horses will now be employed with the routine of the farm, consisting principally of tillage and seeding of the Lent corn land, also chain-harrowing the pastures and meadow land where dung or compost have been laid on during the past winter. This month, too, when the weather is favourable, the horses should be employed carting out of the woodlands any timber cut for repairs, also the underwood as made into hoops, hop poles, spar wood or faggots, for if this work is too long delayed it injures the successional growth of underwood by breaking off young shoots off the stools. The woodlands should also be attended to by open draining where the soil is too wet, otherwise the best kinds of underwood will not flourish, and alder, withay, and such like will be the only produce. The growth of timber likewise may also be greatly promoted upon many woodlands, and where draining is required the experienced eye can immediately detect the damage going on by the stunted appearance of the timber growing thereon. This is also the latest time at which timber can be set out for cutting; and as most estates have some woodlands interspersed with the arable and pasture lands, the growth of timber should be made a double question for consideration—viz., agriculturally and ornamentally, especially where timber is found in the fences or hedgerows. We know of many farms where the timber standing does not pay 1 per cent. in its annual growth. Let this be compared with the value of money, to say nothing of the damage done to adjoining fields by the shading of trees; therefore where timber is required for repairs the first trees to be cut are those which are standing in the wrong place agriculturally. The next to be cut are those which are ripe and making but little or no growth. Again, where trees in woodlands and coppices stand within 80 feet of the outside adjoining cultivated land, those also should be cut.

Hand Labour.—Men will now be employed sowing artificial manures on the wheat, also behind the drill for Lent corn upon both barley and oats where sown after a straw crop, such as wheat. The clover seeds should now be sown, and few men now-a-days can sow well enough by hand, therefore it must be done by the seed barrow, and it is best to sow the seeds at twice—that is, lengthways and crossways. This is the best way to avoid vacancies caused by careless men wheeling the seeding barrow. In the purchase of clovers and grass seeds great care should be taken to secure seeds which are perfectly clean. Now this is sometimes scarcely to be observed by the naked eye, for the weed seeds are many of them so small. We always use and recommend the use of a pocket magnifying glass as the best means of detecting these minute weed seeds, some of which resemble very much the seeds of clover and grass seeds.

ARTIFICIAL INCUBATION.

(Continued from page 234.)

M. MALEZIEU proceeds to say, "There is (in Egypt) generally an incubator for every fifteen or twenty villagers. The people bring their eggs, get an acknowledgment for them, and return at the end of twenty-two days, generally to receive two chickens for every three eggs. The chickens so hatched require the greatest care, especially during the first two or three weeks, and are commonly reared by women. They often have three or four hundred of them at once, and keep them as warm and dry as possible, putting them upon the terraces on the tops of their houses, and at night giving them shelter. The quantity of chickens annually hatched in the incubators in ancient Egypt was a hundred millions, and even to this day thirty millions are produced."

Such, according to the best authorities, was the Egyptian method. We now come to the artificial hatching in Europe. All the earlier attempts at it were evidently copies of the system just described; not to mention the Greeks and Romans of old, there are many vague allusions to it in chronicles of the middle ages. It was tried in Sicily, Naples, Malta, and Poland. A Grand Duke

of Tuscany, according to Thouvenot, "to satisfy a commendable curiosity ever characteristic of the Medici, brought from Egypt an expert in the art of hatching chickens, who produced them artificially at Florence just as well as in Egypt." France seems to have been specially the home of such experiments. Charles VII. set up a hatching establishment at Amboise in 1415, and Francis I., more than a century later, one at Montrichard. There is nothing to lead one to conclude that either of these royal experiments was practically successful. A Spanish priest, Juan Gonzales de Mendoza, had written a treatise on Egyptian and Chinese egg-hatching. This was translated into French in 1600, but from that date we have not before us any accounts of the art being practised in France till the first half of the last century. Philip Duke of Orleans, Regent during the minority of Louis XV., was a man of science, and also intimate with the celebrated and scientific M. Reaumur. The latter in his most interesting book on artificial incubation has left us an account of the Duke's purpose, defeated unfortunately by his death, of bringing an Egyptian to France to instruct people in the art. We will translate his observations on the subject. "The profit derived in Egypt from hatching-houses has long made me wish to see them established in France, and we should have had the pleasure of in Paris seeing the birth of thousands of chickens on one day and in one machine, like those in Egypt, had not a too early death taken from us that Prince, so accomplished in all the arts and so zealous for their promotion, in whose hands the sovereign power had been placed during the King's minority. We should have been spared preliminary experiments which are not generally successful, for one seldom oneself foresees all that easily might be foreseen. The late Duke of Orleans had sent to M. le Maire, then consul at Cairo, a memorandum full of questions which I had drawn up on the method of hatching chickens in Egypt without hens. M. le Maire was not content, by way of answer, with getting a memoir of the Père Sicard, containing many useful and curious directions, and which has since been published with little alteration. He did more. In a letter which I still have in my hands he offered to send to France for a moderate remuneration one of those men whose regular occupation is chicken-hatching. The aid of one of these Egyptians could not fail to be of use if one wished to set to work on as grand a scale as in Egypt, and at once to hatch forty or a hundred thousand eggs; but I have always been of opinion that the facilities for regulating the heat which the thermometer gives us obviate the absolute necessity of the help of a Bermean, for one would only begin, as it is always wise to do, with experiments on a small scale. Those which I am going to record will prove that this is no presumption on my part as to the point of success we may reach with our present knowledge."

This translation is from M. Reaumur's remarkable book published in 1749, of which we possess a copy. It is in two volumes, replete with quaint woodcut illustrations and diagrams. Its title translated is, "The art of hatching and rearing in all seasons domestic birds of all kinds, either by heat derived from dung beds, or by that of ordinary fire." With Reaumur a new era in the science of artificial incubation began. As far as we can ascertain all previous European experiments had been but imitations, more or less correct, of the Egyptian system. Reaumur also tried it, but his success with it being very partial he made many further experiments. On the whole he might be called rather successful in suggestion than in practice; he opened the way, as is often the case with great inventors, for others to profit by his failures. No book on the subject of artificial incubation has to this day, as far as we are aware, come near to his in point of completeness. It is a work, we believe, now difficult to procure, and we therefore shall not hesitate to translate passages from it, and to give as far as is compatible with our scope an abstract of its general information. In his first chapter Reaumur makes some prefatory remarks about the degree of heat necessary for the development of the germ in incubation which are worth reproduction, and which may throw some light on the stories which we hear from time to time of strange fosterparents undertaking the care of eggs and chickens. "The degree of heat necessary for hatching chickens is as nearly as possible that of the hen's skin, and what is worthy of remark, of the skin of all domestic birds of all known kinds, and probably too of all other kinds. I will not recount experiments by which I could prove this, and which I have made upon kinds of eggs that one never before thought of setting. I am relieved from that necessity by the daily experience of the poultry yard. We give the same heat the eggs of a Turkey or a Duck, we give the Turkey hens' eggs or Ducks' eggs, or the Duck hens' eggs; the young ones hatch neither sooner nor later under a different species of bird to that which laid the eggs. It is worthy of remark, too, that the degree of heat is nearly the same as that of the skin of quadrupeds and even of human beings. So Livia ought to have succeeded in her attempt, according to Pliny, to hatch a chicken in her bosom, if she had the patience to keep an egg there as long it ought to be covered by the hen."

Reaumur, after giving a description of the Egyptian incubation which we have already related, and attempting to reconcile the

discrepancies in the accounts of different travellers, goes on to mention modern attempts in France to hatch eggs in a somewhat similar manner. His idea was that the difference in the French climate and the impossibility of at once obtaining the fabulous numbers of eggs procurable in Egypt would make it undesirable, if not impossible, to start hatching establishments on so vast a scale in France; but that a little scientific study and much practical patience would make it possible to utilise heat produced for other purposes and not duly economised in such a way as to raise a considerable number of chickens with little trouble and cost. The ovens of bakers and confectioners at once occurred to him as ready-made incubators, and the cunning of those tradesmen in the regulation of their heat as a step gained in the direction of the Bermean secret. The furnaces, too, of glassmakers and ironworkers, never extinguished, might all be turned to account. He certainly was an enthusiast, but a practical one. He persuaded the superiors of two religious establishments in France to let him make all arrangements for the hatching of eggs in their baking house. These experiments were most interesting, as showing the manner in which by practical intelligence plans ready to hand may be adapted for incubation. The first of them was made in the grand establishment of St. Sulpice. We will give a brief account of it. At the end of the bakehouse Reaumur found two vaulted ovens; grand ones they must indeed have been, for during the greater part of the year 2400 lbs. of bread were daily baked in them. Above them and under the roof of the building was a chamber with one door in the same wall as the oven doors opening into the bakehouse, and one window opening to the external air. Its area was 18 feet by 11 feet, its height 6½ feet. Aided by his friend and fellow worker in science, the Abbé Menon, he at once set to work making experiments as to the temperature of this chamber. They put many thermometers about it in different places and at different altitudes from the floor. These showed that at certain places in it the degree of heat necessary for incubation was maintained. What is most worthy of remark is, that after the fires had been let out for twenty-seven or twenty-eight hours they found hardly any variation in the atmosphere. Reaumur's opinion was that "the heat taken in by walls and floors after having been for many months exposed to a continuous fire, or a fire with only regular intermission, is not subject to sudden changes." This was an observation of great importance, and one which inclines us to the opinion, which we shall give when we come to generalise from these many particular examples, that the work of artificial incubation is far easier on a large than on a small scale. Encouraged by these discoveries Reaumur proceeded to superintend the placing of some dozens of eggs in a basket in this chamber. The nuns attended to them with an assiduity little short of that of a hen, regulated the heat by means of the door and window, and were in due time rewarded by a fair hatch of chickens, though a large number of the first batch died in the shells, doubtless owing to the excessive dryness of the atmosphere. A point had certainly been gained: with a very rude apparatus, capable of almost infinite improvement in the way of ventilation, eggs had actually been hatched. Subsequently a portion of the chamber was partitioned off, and a kind of wooden table with tiers of shelves one above the other (like a whatnot) was constructed, so as to command at once slight variations of heat according to the height of each shelf from the ground. From these improvements resulted a far greater measure of success, and artificial incubation became one of the regular employments of the establishment.—Q.

(To be continued.)

VARIETIES.

IN "Nature" (vol. xvii. page 372) an account is given of the difficulty met with in Australia in getting bees to work after a few years. A correspondent calls attention to the fact that a similar difficulty occurred in California, where it has been obviated by a systematic abstraction of the honey as the bees collected it. If this were tried in Australia it might possibly meet the difficulty.

—ROOKS AND ROOK-DISASTERS.—A farmer in the parish of Retford (says a correspondent) is in the habit of treating his seed wheat with tar (one pint to three "strike" of wheat), to which he afterwards adds a very small quantity of finely sifted quicklime, which serves to prevent the grains from adhering together and clogging the drill. He finds this treatment a complete protection against the depredations of birds, so that he is spared the expense of bird "tenting," and the cost is only about 1½d. per acre. This year, however, he found that his supply of prepared seed corn fell a little short, and therefore he finished the last three rows of the field with ordinary wheat. On the very next day he found that the rooks had discovered the unprotected part of his field, and were engaged actively upon it, while they did not attempt to touch the land where the tarred wheat had been sown. —(Sussex Daily News.)

—AMERICAN MEAT.—The quantity of American beef and mutton landed at Liverpool last week was again very large. Five steamers arrived in the Mersey, having on board 5354 quarters of beef 1559 carcasses of sheep, and 585 dead pigs. There were no

From observations taken near London during forty-three years, the average day temperature of the week is 56.8°; and its night temperature 35.5°.

ROSE NOTES ON THE PAST AND PRESENT.

NOW that we have passed the end of March I suppose we may consider that the winter is over. The winds are indeed still very cold, but the sun is so high in the heavens that we are pretty sure to have sunny days whatever frosts we may have by night. I do not know what may have been the case with my brethren in the midland counties or in the north, but here in the west I have no hesitation in saying we have had one of the mildest winters on record. We have positively had no snow till the last night or two; a few flakes fell on the 23rd and 25th of March, but they were succeeded by rain, and some few weeks ago we had snow or sleet which lasted for about half an hour, but which melted as it fell.

I never knew vegetation so forward. There is at present a Lamarque Rose in bloom on my house and a Solferatro on the church; the Rose plants also are looking uncommonly well, particularly the young trees purchased last autumn. The night frosts and cold winds now prevalent are doing positive good to the Roses, whatever they may be doing to the fruit trees. They are arresting the growth of the Roses, and so doing good service in checking the plants at a time when they can bear it much better than in May, when such frosts are very often fatal to all the tender sorts. So far, then, as the season has as yet advanced the Rose-grower has had everything in his favour.

Most of the schedules are out; the Royal Botanic Society holds its show so early as June 12th. Whatever Roses do they expect to have on that day? Their schedule, however, is so poor and meagre that it does not much matter to amateurs what day they fix. They only offer one class for amateurs, and that a by no means easy one. Twenty-four trebles tax the resources of most rosarians, and I do not think I overstate the case when I say a man who wishes to show in that class ought to have at least a thousand plants. If these lines meet the eye of any member of the Council of the Royal Botanic Society I hope I may be pardoned for urging the claims that amateur Rose-growers have on the veteran Society, and that I may express the hope that in future years it will be more liberal in this matter and offer more classes in which the amateur cultivator may exhibit the queen of flowers. I feel sure attention need only be directed to this point and some alteration will be made.

The Alexandra schedule is also out; their show is fixed for Saturday, the 22nd of June. Saturdays are most awkward days for many rosarians; but so long as the early-closing rules are in vogue on that day so long, I suppose, will everything that is good take place on a Saturday. The Alexandra and Crystal Palace Shows, the splendid series of orchestral concerts at the Crystal Palace, undoubtedly the best in England, and second to none in Europe, the Saturday Popular Concerts at the St. James's Hall—everything is on a Saturday, and a hardhearted railway company like the South-Western insists upon giving no later train than the one leaving at ten minutes to five. What are poor

country parsons to do? Miss half the show, or miss your duty, or miss the show altogether. Any day but Saturday, is our prayer. No day but Saturday, is the reply of the Directors. The Alexandra has reduced the amount given in prizes to amateurs and in other ways has curtailed the schedule: £5 is now the chief prize, while £10 is given to nurserymen. The Crystal Palace used to make the two prizes equal.

The National Rose Society has issued a most liberal schedule, but as I am not quite sure whether it is definitely and finally settled upon I will not mention it in detail. The Hereford day is fixed, and so is the Ludlow, but Birmingham as yet makes no sign. The Aquarium and Royal Horticultural schedules have not reached me, nor do I know whether the former intends to have a show. Torquay has again issued a most illiberal schedule, and I do hope the Committee will yet amend it. Fancy! for thirty-six Roses, distinct, the Society offers £2, £1, and 15s.; for twenty-four, £1 10s., 15s., and 10s.; and for twelve trebles, £3-cup, £1 10s., and 15s. These are for amateurs. The nurserymen fare equally badly: for forty-eight singles they are to have only £2 10s., £1 10s., and £1; and for forty-eight trebles, £5, £3, and £2. If this Society were to reduce the number of classes exactly by one-half they could offer liberal prizes and attract Rose-growers from all parts. As it is their money is as good as thrown away, if a repetition of last year's show takes place, so far as the open and nurserymen's classes are concerned. Secretaries of societies cannot make a greater mistake than to offer so many classes and with so little money as prizes. The old schedule of the Crystal Palace might well be taken as a guide:—For nurserymen: 72, 48 trebles, 24 trebles and 24 singles, and 12 Teas and Noisettes. For amateurs: 48, 36, 24, and 12 distinct, the class for twelve being a close class. The only mistake about their schedule was that there was no class for Teas in which amateurs could compete.

And now, having stated the various schedules, may I offer a word of advice to my brother rosarians? I remember once taking up Roses to South Kensington. I had staged in every class, but a thunderstorm came on while I was cutting and my blooms were much knocked about. I showed them to Mr. George Paul. He advised me in his usual kind way to take out the best from each box and make one good twenty-four, or even twelve. I did not do so, and what was the result? I was not placed in a single class. "You amateurs try to do too much," was his remark on that occasion, and I repeat it in this letter—we try often to do too much. There are very few amateurs, indeed they can be counted on the fingers of one hand, who can show forty-eight, thirty-six, twenty-four, and eighteen trebles well. Mr. Baker can and Canon Hole, Mr. Pochin, Mr. Jowett, and Mr. Arkwright; but who else? To show forty-eight distinct varieties you require a stock of at least sixty varieties, and fifty to a hundred plants of each; so that you should have at least four thousand plants. But if we can but curb our ambition and confine ourselves to the smaller classes we may do very fairly. Last year at the National I showed in all the big classes and was fourth in each, but at the Alexandra I confined my attention to

twenty-four trebles, and there was first. I only mention this to strengthen my point. Let us in the autumn decide what classes we mean to show in next year, then give orders to the nurseryman in accordance with our choice of class.

A man who wishes to show twenty-four trebles had far better buy fifty plants of thirty sorts than thirty plants of fifty sorts. The same rule holds good all the way down the schedule. Where I have fifty plants of a leading sort Mr. Baker or Mr. Jowett has most likely five hundred. These are all growing in lines together, and it is as easy for Hercules to cut good blooms for all the classes in the schedule as it is for a pigmy like myself to cut for one. Do you know what Mr. Baker did on one great occasion? He not only cut blooms for all the classes, but actually cut a spare for each bloom; so that he took up to the show something like 450 blooms! But how many of us can do this?

Many a poor forty-eight has been staged which would have made a splendid twenty-four. It is true, of course, that the prizes for the large classes are much more valuable, and that the fourth prize for forty-eight is often as good as the first for twenty-four; and it is not less true that there is much less competition in the higher classes, so that the chances are much greater that you get the fourth prize for forty-eight than that you get the first for twenty-four. Yet everyone who loves the Rose for the Rose's sake, and that exhibits it simply from a desire to tilt a lance at the tournament of the queen of flowers, will not be guided by such miserable and selfish principles as making prize-money.

After you have decided upon your class, the next aim is to try and get an even stand; I mean by this Roses of much the same size and quality throughout, and this is all the easier when you confine yourself to the smaller classes.

I remember once at South Kensington Mr. Laxton showing thirty-six Roses in a box made for twenty-four. They were all small even blooms, of good form and fresh colour. He, cunning man, knew their weakness and also their strength, and so to conceal their want of size, and also to show the even nature of the exhibit, he put them close together; so the judges when they came to the stand (how well one can imagine the Rose king who reigns at Cheshunt saying, "A nice even lot, perhaps a little undersized, but fresh and of good form, much superior to that lot, which reminds me of a lot of Cochinchina eggs mixed up with bantams") gave him the prize.

The setting-up of a stand of Roses also is a great matter. Anyone who has seen one of the great nurserymen set up a stand will be amazed at the difference an expert exhibitor makes in a few minutes to a prize stand. The box when opened displays a grand lot of blooms, all of them level with the moss and displaying great humility. The master then sets to work. I must not again say what preliminary touches he gives to his own apparel lest I should again offend some sensitive person. He begins to set up each bloom about 2 inches from the moss, and when he has done the effect is marvellous. Each bloom seems to be saying, "Look at me; am I not a beauty? Don't attend to my sister, she's a conceited Tea. Behold my charms. I am not the least bit of a prude. You may look at my charms." Every now and then you perhaps see a rather small bloom, but if so she is what we may call a perky one—i.e., has a character of her own. There is something about the curl of her hair or her blushing cheeks that will win your love, even though she be somewhat of a dwarf as to size. And so we have another rule—Don't put in a comparatively small bloom unless there is some other distinguishing excellence which will redeem her position among a lot of giants. It is no good putting a poor weak bloom in the bottom row in the hope of its being undiscovered. A judge has the eyes of Argus.

I have written these few notes as hints to beginners, not in any way venturing to offer advice to old stagers; but in your columns letters have appeared from neophytes and others, and to them perhaps a few hints may be acceptable. What I have said may not be worth much, but it is at least the result of much experience in Rose-showing. If it is not thought anything of by the cognoscenti let them dismiss this article with the simple reflection that it is only written by a—WYLD SAVAGE.

FRUIT PROSPECTS.

In the county of Durham we are having our share of the present very rough weather. On Saturday morning we had 2 inches of snow, and my thermometer lying exposed on the woodwork of a cold frame registered 10° of frost, Sunday

morning 8°, but I rather suspect my instrument is 2° too low. Gooseberries are just peeping through the foliage used for a protection against such weather, my bushes being all grown with a nice round top. I do not expect they are much worse. As a rule, such pruning secures a half crop, and for this reason I never grow them thinly trained-out as though I wanted the fruit for exhibition. What Pear blossom there is, is ready for expanding; but I have not the slightest faith in a remunerative crop of either Apples or Pears, as I do not think the fruit buds were sufficiently perfected last season. My Peaches in tubs—of which I enclose a leaf of Lord Palmerston, Princess of Wales, and Royal George—have set their fruit fairly well, Early Alfred the best, and Noblesse the worst of the twelve varieties. Last year in pots I had much pleasure in them, and I have great expectations of the present. Apricots, Nectarines, and Plums in a cold house are now in full bloom, and are healthy and pretty. This way of growing fruit is really an interesting occupation. My Vines are breaking with great vigour, and two canes of Frontignans and all the Alicantes are showing promising bunches. I used fire all the twelve months moderately, and the canes were well ripened, but I have a dread that late houses without fire heat will be in a worse position than they were last sunless summer. It would be interesting to hear what others have to say upon this subject. —JOSEPH WITHERSPOON, *Red Rose Nurseries, Chester-le-Street.*

[The Peach-tree leaves are clean, healthy, and fine.—EDS.]

VEGETABLE CULTURE.

CHAP. XIII.—CELERY.

CELERY is a native of Britain, and is generally found growing wild in marshy places. Although it cannot be regarded as being of such great importance as an article of food as many vegetables, it is nevertheless cultivated in almost every garden, and in many instances great attention is paid to it. When a few plants are wanted for soups earlier than the main crop, a little seed is sown in heat about the end of January. Celery seed germinates quickly in heat, and the plants grow quickly afterwards. The seed should therefore be sown thinly, and the plants must have plenty of light. As soon as they have formed four or five leaves they should be transplanted either into boxes or a frame on a slight hotbed, the plants having room to develop. The soil should consist of about half leaf soil or decayed manure, and the other half loam. Before planting, this mixture should be made very firm, as the plants thrive better at first and lift better afterwards when that is done.

In raising young Celery plants there are two very important matters which must be attended to; these are never to allow the plants to become dry at the root, and to keep a very sharp look-out for snails. I do not know a vegetable that these pests devour quicker than young Celery plants, and when the plants are very small a single snail will eat dozens of them in one night. The best way to prevent this occurring is to destroy every snail on its first appearance. If it is not convenient to do this dust the plants over with powdered lime, and repeat this if necessary. Plants raised in heat will be considerably advanced in growth by the beginning of April, and during that month they should be gradually exposed to the air until they are quite hardened-off and ready for planting-out early in May.

Seed for the main crop of Celery should be sown about the middle of March. We have tried various ways of raising the plants at this time, and we make it a system now of sowing the seed in boxes, which are placed either in a slightly heated house or close frame. A frame is the best place in which to set the boxes as soon as the plants are formed. Where no protection can be given the seed should not be sown until about the middle of April; it may be then sown in a sheltered place in rich soil out of doors. The plants must not be allowed to become crowded before they are transplanted. When a frame can be spared transfer them to it. The frame should stand on a hard bottom, and rich soil should be placed in it to the depth of 6 inches, and be made firm before dibbling-in the plants 3 inches apart each way. Water them immediately afterwards, and shade from bright sunshine if necessary for a few days. During the time they are growing in the frames too much attention cannot be paid to supplying them with water. The plants will be ready for planting-out finally when they are about 6 inches high. Previous to planting they must

be fully exposed to all kinds of weather night and day. Short strong hardy plants receive no check when planted out.

The following remarks on general culture apply to plants raised early or late. No great attention need be paid in selecting soil in which to grow Celery, as its successful culture depends more on what is put in the soil than the soil itself. We have grown good Celery in both very light and very heavy soil. Of the two we prefer the latter. Heavy soil is best in a dry summer, but light soil preserves the Celery best in a damp winter. The trenches in which to grow it are of very different widths. Some make them only sufficiently wide to hold one row; others, especially market gardeners, often grow eight, ten, and twelve rows in a trench. The single-row system is very convenient, but not much more so than when two, three, or four rows are planted in the same trench. We always plant from two to four rows, and find it suit admirably. Ten inches is quite deep enough in light, and 6 inches in heavy soil for the trenches, and a width of 6 inches should be allowed for each row. The trenches should be prepared a few days before they are required for planting, and the top of the ridges between them should be made quite level. As soon as these are finished rows of Lettuces, Spinach, or any quick-growing crop may be sown, which can be used before the Celery is ready for earthing-up. Without a good quantity of manure good crisp Celery cannot be grown. We generally place manure (cow dung) in the trenches to about the depth of 6 inches, and dig it in. When the trenches are only about 6 inches deep the manure nearly fills them, but it settles down; when the soil is light and dry it should be trodden firmly. When the soil in the trench is clayey the young plants do not grow kindly in it at first, and it is of great assistance to them when sufficient fine soil can be placed round their roots to give them a quick start. In planting all the roots possible must be secured, and they must be placed in the soil carefully, not cramming them down roughly.

It is an advantage to plant in dull showery weather, but this cannot always be had; and when the weather is dry and bright the plants must be thoroughly watered immediately after planting. Should the weather continue dry it will be necessary to water them twice a week until they have begun to grow; but when they get a thorough hold of the manure drought has not so much influence on them. In extremely dry weather, however, care must be taken that the plants, no matter what size they may be, do not suffer from dryness at the root, as it is from that cause that Celery "bolts," or runs to seed prematurely. I may remark here that with 6 inches between the plants across the trenches, 12 inches should be given them the other way. After planting they must be kept free from weeds by having the Dutch hoe run between the rows until the plants meet.

Earthing-up should not begin until the plants are at least 15 inches high; the short outside leaves and suckers must be broken-off before the soil is applied. It must be broken down fine, and not a particle must be allowed to go between the leaves or in the centre of the plants. We generally apply the earth three times before the heads are completely blanched. Worms do not injure the heads if a little soot is sprinkled between the plants each time before earthing. Earthing-up should only be done when the leaves and soil are dry. Where it is not convenient to employ two persons in earthing-up, each plant may be tied-up with a piece of matting to prevent the soil from going in the centre; but the tying must be removed as soon as the earthing is finished.

When the autumn and winter are severe it is generally necessary to protect Celery, and one of the best materials which can be used for this purpose is dry fern. Straw is nearly as good, and in very cold localities it is often necessary to employ mats, shifting them off and on as required. Celery is most in demand from October to February, but we have plenty of it now; it has been lifted from the trenches for some weeks and laid in by the heels amongst ashes, which is a good way of preserving it when it is necessary to clear it from the ground to get other crops on.

The Celery fly is very troublesome during some seasons and in some localities. It feeds on the leaves, and the parts attacked blister. If not checked this ultimately spoils the plants and crop. As in the case of other insects, the best way of staying their progress is to kill the grubs before they become numerous or have time to do harm, and this can easily be done by pinching every one between the finger and thumb as soon as they make their appearance. Soot dusted on the leaves will also keep them in check. We grow and recommend Major

Clarke's Red, Cole's Superb Red, and Incomparable White.—
A KITCHEN GARDENER.

GREAT INTERNATIONAL HORTICULTURAL EXHIBITION AT GHENT.

FOR a period of fifty years exhibitions which have attracted the presence and secured the co-operation of the leading horticulturists of Europe have been held every five years in Ghent. The present, being the tenth quinquennial, naturally commanded more than ordinary attention, and great efforts were made to render it equal or rather superior to the memorable gatherings of the past.

Apart from the interest attaching to the extensive and valuable collections of plants incident to such an occasion, the opportunity afforded for the assembling of horticulturists of various nationalities, and under such congenial auspices, renders these great exhibitions real red-letter days in the horticultural world. They are events, too, made additionally enjoyable in consequence of the unfailing courtesy of our Belgian friends, whose frankness of welcome and open-handed hospitality are proverbial.

The risks attendant on sending valuable plants across the Channel thus early in the season were this year unusually great. The weather on the day previous to dispatching the collections—the packing day, (Tuesday, the 26th ult.)—was one of the most bitterly cold of the entire winter. With 10° of frost in the morning, a drifting snow-and-ice wind blowing a gale all day, nothing but the utmost boldness and extraordinary enterprise could have impelled the English exhibitors to have proceeded with their work. They, however, ventured and sustained the credit of their country in a manner as gratifying as it was successful. Mr. BuW won all the chief prizes in the classes for new plants. Mr. Wills triumphed over all comers with his unique collections of *Dracenas*, winning also with *Nepenthes* and *Yucca filamentosa variegata*; and the old firm of Rollisson proved itself vigorous by securing the chief prizes in the classes for Orchids and Cape plants. Messrs. Veitch and Williams did not compete in the classes, but their miscellaneous collections won high honours. Such results are ample rewards for the risks incurred by the transit of plants across a stormy sea and their long detention in the Exhibition—March 31st to April 7th. The visitors, too, will not soon forget the passage across the Channel on Friday the 29th ult. A more unpropitious morning for starting for a flower show could scarcely be imagined. Heavy snow left the London streets at seven o'clock in a state of half-congealed slush. Flowers were about the very last things that ought to be out in it, and fears were expressed that a continuance of such weather would prove fatal to the success of the International Exhibition. At Dover a gale was blowing, the train could not be run down to the pier, umbrellas were worse than useless, and big waves now and again washed like a sluice over the Admiralty pier. There was so much sea on that the Ostend boat could not leave at all, and we resolved to make the passage to Calais. Ere five minutes had elapsed from the departure from the pier most of the passengers were engaged on their own private affairs, and the deck was felt to be a more pleasant locality than the cabin. So protected with overcoat and rugs we faced the weather, lest sympathising too keenly with the misfortunes of our friends we too might fall victims, a fate from which we were fortunately preserved. Entering Calais two hours and a quarter afterwards we just grazed the bar and escaped four hours' additional tossing by only a few minutes, and after a tedious railway journey reached Ghent at eight o'clock. At the Hôtel Royal we met a host of English friends and all besides that we required.

Rain was the order of the day on Saturday, and as a consequence of the bad weather arrangements for the Show were scarcely complete at the stipulated hour. At about eleven o'clock we were summoned into the Committee room, and the President addressed the members of the Jury in a short address.

"Sixty years ago," observed the Comte de Kerchove de Denterghem, "there met in a small tavern a short distance from the present place a few gardeners and amateur florists. Then and there it was that the idea of the first floral exhibition ever held in Ghent took its rise. Though modest in its pretensions it yet had unexpected eclat. It was composed of fifty plants, and a smoky room sheltered them; but even then the love that the Ghent population bore to flowers was so great that the Exhibition was admired by a crowd of visitors. The Society, so modest in its origin, lived and increased rapidly in the number of its members, and strengthened year by year the success of its exhibitions. To-day is the 141st time that the Society invites to it the lovers of plants, and vast though our usual places of exhibition have been, they are too confined to contain all the wonders which the plant establishments of exhibitors have sent us. We find in this eagerness that on all sides we receive in reply to our invitations a flattering recompense for the efforts made by the Society for the advancement of horticulture."

The President, who was loudly cheered, then dismissed the Juries to their duties, briefly remarking on the nature of the special prizes provided, and thanking especially the English Committee of the Van Houtte memorial for honouring, in the form of prizes offered, the memory of the valiant horticulturist. He also thanked Mr. William Bull for the handsome silver cups to be competed for at the present Exhibition.

At the breakfast which followed the judging the Comte de Kerchove de Denterghem spoke a few words of welcome and thanks for the exertions of the Jury.

On Sunday happily we had a sunny day, and the Exhibition was soon a very gay scene. Brilliant uniforms—military, diplomatic—and fashionably dressed ladies filled the rooms and houses. Guards of honour from two regiments formed along the side of the road on each side of the entrance, and at two o'clock the King and Queen arrived attended by the Count and Countess of Flanders and other members of the Royal family and a large suite in full gala uniform. The Royal party were conducted round the Exhibition by the President and M. Verschaffelt, and both the King and Queen spoke to many of the exhibitors and other distinguished botanists and horticulturists present. He expressed his great pleasure to see so many from England, and after a stay of two hours and a half the Royal party left; the rain had recommenced, and it was blowing a cold easterly wind. As it happened almost the whole of the English section found themselves together near the entrance as their Majesties departed, and a thorough English cheer seemed to astonish the natives, and was duly acknowledged by the King.

It is said that the town of Ghent is not in the Royal favour just now, as disloyal manifestations had on a former occasion been made here; but whether for this reason or not we cannot say, but the banquet was not honoured with the presence of royalty. The President was supported on his left by the Duc Decazes and on his right by the Minister of the Interior; the Procureur-General and various Government functionaries occupied seats at the upper table, and at half-past eight we were ushered into the adjoining Opera House to hear Verdi's *Ballo in Maschera*.

As before observed Messrs. Veitch and Williams only sent honorary collections, but these, as might be expected, are of sufficient merit to arrest general admiration. Both exhibitors were awarded gold medals of the first class for fine groups of new and choice plants. Messrs. Veitch also receive a gold medal for what is no doubt the grandest collection of one hundred Hyacinths ever seen in Belgium. These noble spikes commanded general admiration. The same firm receive a silver-gilt medal for a group of Cyclamens, and Mr. Williams has the same award for a similar collection. Both the groups are excellent.

Messrs. Veitch's miscellaneous collection contained the following plants:—*Acalypha Macafeana*; *Anthurium Veitchii*, a remarkably fine specimen, which is greatly admired; *A. Warocqueanum*, fine specimen; *Aralia Kerchoveana*, new; *Erythrina Baptistii*, new and fine; *Hæmanthus cinnabarinus*; *Croton Earl of Derby*, *C. maculatus* Katonii, *C. fasciatus*; *Crinum Verschaffeltianum*, new, and commands general approbation; *Stenospermum Walisii*; *Lomaria discolor bipinnatifida*; *Euryclis australasica*; *Adiantum palmatum*, *A. speciosum*, *A. Lüdemannianum*; *Gymnogramma Muelleri*; *Tillandsia Zahnii* in flower and a source of considerable attraction; *Araucaria Rulei*; *Brahea filamentosa*, a fine specimen; *Cypripedium selligerum*, and the new and chastely beautiful *Magnolia Halleana* syn. *stellata*, this plant proving a general favourite with the visitors. The group is not large, but is very valuable, the Orchids having been left at home owing to their fragile nature and the extremely inclement weather.

Mr. Williams arranged a larger and very fine group, which is brightened by Orchids which the sturdy horticulturist ventured to bring. These consisted of *Cattleya intermedia*; *Cypripedium Dominicanum*, Lowii, niveum, villosum, and Warnerii; *Dendrobium crassinode*, *Wardianum*, nobile, and *chrysotoxum*; *Lycaste Skinnerii*; *Masdevallia chimera*, ignea, and ignea superba; *Odonoglossum Alexandræ*, cirrhosum, gloriosum, and *Pescatorei*; *Oncidium sarcodes*, *Phalenopsis Schilleriana*, and *Restrepia elegans*. The ornamental-foliated plants comprise *Aralia Veitchii*; *Anthurium floribundum*, *Patinii*, and *Scherzerianum*; *Anæctochilus petala*, *Calamus ciliaris*, *Cyanophyllum magnificum*, *Cocos Weddelliana*, *Cycas intermedia*, *Chamaedorea glaucifolia*, *Cupania filicifolia*, *Cordyline indivisa*; *Crotoms Burtonii*, *Bismarckii*, *Disraeli*, *camptophyllum*, *Jamesii*, *Mooreanus*, *Mortii*, *mutabilis*, *Queen Victoria*, *Prince of Wales*, and *volutum*—a fine assortment; *Dracæna Bausei*, *Berkleyi*, *Elizabethæ*, *Frederickii*, *Goldieana*, *Mrs. Bause*, *Imperator*, *Renardii*, *Salmonea*, and *Scottia*—a rich collection; *Dæmonorops palembanicus*, *D. Lewisianus*, *Dieffenbachia marmorata*, *Encephalartos cycadefolia*, *Geonoma gracilis*, *Gleichenia Mendelii* and *G. rupestris*, *Kentia australis*, *Macrozamia Dennisonii*, *Panax laciniatus*, *Sarracenia Drummondii* and *S. purpurea major*, *Thrinax elegantissima*, *Yucca filamentosa variegata*, *Habrothamnus elegans*, *argenteus*, and *Tillandsia Lindenii*. Of *Nepenthes* we observed *Chelsonii*, *Courtii*, *intermedia*, *Rafflesiana*, and *Sedeni*; and Ferns were represented by *Lomaria discolor bipinnatifida*, *Microlepia hirta cristata*, *Adiantum lunulatum* and *palmatum*, and the distinct Fern, with its distinct name, *Anemi-*

dictyon phillides tessellata. This is a noble group of plants quite worthy of England and Holloway.

Extra exhibits are also contributed by Belgian exhibitors, but only one gold medal is awarded—namely, to Mr. D. Vervaeke, sen., for an excellent group of *Azalea indica*. Mr. Van Houtte has a silver-gilt medal for a fine collection of *Bertolonias*; and silver medals are awarded to M. Baumann for *Araucarias*; M.M. Vanderzwalm, Van Hoecke Peeters, Spilthoorn, Leopold Haec for divers exhibits; and to M. Schwartz of Lyons for *Roses*.

In referring to the classes it will be appropriate to first summarise the signal successes achieved by the trio of English competitors, Messrs. Bull, Wills, and Rollison. Mr. Bull exhibits in ten classes, and secures seven first, one second, and two third prizes, represented by five gold, four silver-gilt, and one silver medal. Mr. Wills competes in five classes, and secures two gold and three silver-gilt medals; and Messrs. Rollison, who exhibit in four classes, have the same number of first prizes—three gold and one silver-gilt medal. Thus, including the awards to Messrs. Veitch and Williams, we find that while the English horticulturists only compete in nineteen classes they secure twenty-four medals, thirteen of these being of gold, ten of silver-gilt, and one of silver, a triumph such as we seldom have the pleasure of recording—a result quite sufficient to make a nation proud of its representatives.

Our readers will next desire to know what plants those famous exhibitors have proved so successful. We will first enumerate Mr. Bull's remarkable contingent. In Class 1, twelve plants in or out of flower recently introduced into Europe by the exhibitor, the gold medal of the first class was won with *Encephalartos Hildebrandii*, *Croton Rex*, *Dracæna Goldieana*, *Bowenia spectabilis serrulata*, *Croton picturatus*, *Dieffenbachia triumphans*, *Lomaria discolor bipinnatifida*, *Carludovica Drudei*, *Cataglyphis Hopei*, *Cibotium Menziesii*, *Dieffenbachia splendens*, and *Aralia splendissima*. In the corresponding class for six plants the following won the gold medal—*Sadleria cyathoides*, *Dracæna Goldieana*, *Bowenia spectabilis serrulata*, *Croton Disraeli*, *Dieffenbachia Leopoldii*, and *Anthurium Veitchii*. In Class 3, for twelve plants in or out of flower introduced into Europe by the exhibitor and not yet in commerce, the gold medal of the first class was awarded for *Panax plumatum*, *Aralia venusta*, *Dieffenbachia Shuttleworthii*, *D. Regina*, *D. Leopoldii*, *Dipteris Horsfieldii*, *Alcasia Johnstoni*, *Croton princeps*, *Pandanus princeps*, *Alsophila undulata*, *Croton cornigerus*, *Doodia aspera multifida*; and in the corresponding class for six plants the following constitute the gold medal collection—*Aralia concinna*, *Davallia fijiensis*, *Dieffenbachia Leopoldii*, *Dendropanax argenteus*, *Anthurium insigne*, and *Zamia princeps*. The eminent Belgian horticulturist M. Linden is second to Mr. Bull in the above important plant classes, and M. Jacob Makoy et Cie., Leige, third in Class 3. The contest between the first-named two exhibitors was unusually keen and close.

In Class 7, for one plant in flower recently introduced into Europe by the exhibitor, Mr. Bull wins with *Hæmanthus Mannii*. M. Linden is again second, and M. Makoy et Cie. third. In the corresponding class for a plant not in flower the prizes go to M. Linden, M. Auguste Van Geert, and Mr. Bull respectively. In Class 9, for plants in flower obtained from seed in Europe and not previously exhibited before the Society, Mr. Bull wins with *Dendrobium Ainsworthii*. In the class for eight Palms of recent introduction Mr. Bull won the first place with *Thrinax barbadensis*, *Plectocoma himalayana*, *Kentia Wendlandii*, *Cyphokentia macrocarpa*, *Drymophleus paradoxus*, *Geonoma Bluntii*, *Martinezia Roezlii*, and *Desmoncus granatensis*; and in the class for three Ferns won him the medal—*Lastrea aristata variegata*, *Cyathea Imryana*, and *Pteris splendida*.

Amongst Mr. Wills's wonderful collection of *Dracænas*, which far eclipse all others in the Exhibition, and secured the gold medal *à l'unanimité*, we noticed the following as a few which specially commanded the attention of the visitors:—*Caustonii* (new), medium size, bronze flaked rosy crimson, some leaves being wholly crimson violet, a seedling from *Magnifica*, very rich; *Recurva*, a remarkable and distinct variety, a stately column of dark recurved foliage; *Anerleyensis*, grand in character and colour; *Mrs. Freahe*, medium, foliage narrow, gracefully arched, fine habit, dark green, margined broadly with cream, faintly tinted, and having rosy pink stems, fine substance; *Gladstonei*, grand foliage 6 inches in diameter, deep bronze, nearly black-coloured crimson; *Leopoldi*, a handsome and stately variety, fine in foliage, and rich in colour; *Alba marginata*, stately, of great substance, valuable for decoration, colour creamy white and green; *Gigantea*, large, foliage 8 inches in diameter, bronze green, heavily edged with cream tinted rose; *Voluta*, the same colour as the preceding, with recurved foliage; *Majestica*, very free and stately, foliage narrow and arched, green suffused with orange red; *Salmonea*, colour of *Majestica*, but plant of more upright habit; *Tillingii*, handsome in habit, foliage 8 inches in diameter, and very broad and recurved, but not so highly coloured as some others; *Wilsonii* (new), a seedling from *Mooreana*, upright growth, very long leaves, bronze green, flaked and edged with crimson and tinted with violet; *Thomsoni*, good habit, broad foliage, very richly coloured; *Willis*, sturdy and handsome, foliage recurved and extremely rich, one of the finest; *Mrs. Wills*, dwarf and constant, white, very distinct; and *Eliza-*

bethæ, dwarf and very highly coloured. The above are only a portion of the grand collection which wins the gold medal of 150 francs offered by the members of the Council of Administration—one of the chief prizes of the Exhibition. M. Van Houtte had the second prize in this class with a remarkably fine collection. In the class for six *Dracenas* not in commerce, Mr. Wills is the only prizetaker with the following fine varieties:—Mr. Freake, *Majestica*, *Alba marginata*, *Willisi*, *Leopoldi*, and *Anerleyensis*; and in that for three plants remarkable for their culture and their beauty he is also in the premier place with splendid examples of *Gladstonei*, Mr. Freake, and *Anerleyensis*; M. Dallièrre having the second prize. It is in these two classes that Mr. Wills takes the silver-gilt medals. The other gold medal he wins in the class for six *Nepenthes*, the prize being offered by the Comtesse de Gomer. The collection was composed of *N. Rafflesiana*, twelve pitchers; *N. Hookeri*, with eighteen; *N. Sodei*, with eighteen; *N. intermedia*, with seven; *N. Courtii*, with four, very fine; *N. Dominiana*, with seven; *N. Chelsoni*, with fifteen; *N. ampullacea vittata major*, with five pitchers. Although this is not the period when *Nepenthes* are in their best condition, the plants exhibited were extremely fresh and healthy. Some of the specimens were small, but others were large and had handsome pitchers. Mr. Wills's remaining exhibit, for which the medal was awarded *par acclamation*, the pair of *Yucca filamentosa variegata*, have foliage about 2 feet long, clearly and finely striped; plants about 2 feet through. They are a pair of handsome specimens, and well merit the silver-gilt medal that was awarded for them.

We pass now to note the successes attained by the Belgian exhibitors. Although, as we have observed, M. Linden exhibits remarkably well in the classes for new plants, the familiar name of M. Louis Van Houtte must be credited with the greatest number of prizes of any competitor. The famed nursery at Gentbrugge appears as formidable as ever, for its ample stores figure in fifty different sections, and in nearly all successfully, for the result is twenty-seven first prizes, eight second, and five third; in all forty.

Amongst the more important of the prizes are the gold medal for twenty new plants in or out of flower (the second and third honours in this class (3) going to Mr. J. C. Moens of Lede and M. Aug. Van Geert respectively); the gold medal for twenty-five stove and greenhouse plants with variegated foliage; the gold medal for fifteen *Pandanuses*; the first-class gold medal for seventy-five *Amaryllises* in flower (the second gold medal in this class (154) going to M. J. Boelens of Ledeberg, and the silver-gilt medal to M. A. Vandenbossche of Leeuwerghem respectively); the gold medal for a hundred *Hyacinths* (the second prize going to M. E. Barnaart & Co. of Haarlem). Greater still than the above prizes was the object of art value 250 francs, offered for six stove and greenhouse plants remarkable for their beauty and their culture. This cannot fail being a very highly cherished prize, for it was offered by the English Committee formed for honouring the memory of the late M. Louis Van Houtte. We congratulate the present owner of the great nursery and the inheritor of an honourable name on the acquisition of this prize. M. Van Houtte also secures a prize of still greater intrinsic value, the object of art value 500 francs, offered by the Comte de Kerchove de Denterghem for seventy-five plants in or out of flower (the remaining prizes in this class (171), the great gold medal, going to M. J. B. de Saegher of Ghent, and the gold medal to M. Vandermeersch-Mertens of Antwerp); and also the liberal prize, an object of art value 300 francs, offered by the Comtesse de Kerchove de Denterghem for 150 *Hyacinths*, thus defeating the Dutch exhibitors, MM. Schertzer & Son of Haarlem, who are second, winning the large gold medal, and A. E. Barnaart & Co., who secure the gold medal in this class. Amongst the other first prizes won by M. Van Houtte were those for *Echeverias*, *Alocasias*, &c., *Caladiums*, *Musae*, *Palms*, *Cycads*, *Azaleas*, *Camellias*, *Rhododendrons*, *Amaryllises*, *Liliums*, *Tulips*, seeds, and publications. The other chief Belgian exhibitors were, among nurserymen, MM. Nuytens Verschaffelt, De Smet, Dallièrre, Ad. d'Haene, Vervaene, De Saegher, Spae, &c.; and amongst the amateurs the President, Comte Kerchove de Denterghem, and M. Ghellinck de Walle are prominent by the extent and beauty of their contributions. They indeed arranged noble collections and worthy of the renown of such famed patrons of the art which they do so much to promote.

The prizes offered by Mr. William Bull to Belgian exhibitors of twenty plants introduced previously to 1873 brought out some excellent collections. The prizes were awarded in the following order—namely, the first prize, a silver cup value fifteen guineas, to M. Massange de Louvrey of Liège; second, a silver cup value ten guineas, to M. Louis Van Houtte; and third, a silver cup value six guineas, to M. Aug. Van Geert of Ghent.

In the Orchid classes for nurserymen Messrs. Rollisson & Sons, Tooting, secure the gold medal of 250 francs for twenty plants in flower, also the gold medal in the class for fifteen plants; in this class M. Beaucarne secures the silver-gilt medal. M. Massange of Liège wins the gold medal for ten exotic Orchids, and M. Van Houtte the first prize, a silver-gilt medal, for fifteen hardy Orchids. In the amateurs' class for twenty exotic Orchids the gold medal of 250 francs is won by M. O. Lamarche of Liège.

Passing the Cactuses, *Echeverias*, *Alocasias*, *Caladiums*, *Marantas*.

Crotons, *Begonias*, we arrive at some important classes—the *Palms*. These noble examples of tropical vegetation always constitute an important feature of a Belgian exhibition. On the present occasion many magnificent examples are arranged, notably by M. Ghellinck de Walle, the distinguished amateur, who secures the gold medals offered for forty and twenty specimens respectively. In the nurserymen's class for twenty-five specimens the gold medal goes to M. A. d'Haene, and in the class for twelve plants to M. Nuytens Verschaffelt. Silver-gilt medals are awarded to MM. Spae-Vandermeulin, Amb. Verschaffelt, and Herrievaux, Paris. *Cycads* were also excellently represented. In the amateurs' class for fifteen plants the gold medal was awarded *à l'unanimité* to M. Ghellinck de Walle. The same exhibitor has the chief prizes in the classes for single specimens remarkable for their beauty and development, the remaining honours going to Comte Kerchove de Denterghem. In the nurserymen's classes MM. Nuytens Verschaffelt and Vander Wouwer, Antwerp, secure the gold medals. The same exhibitors have the principal prizes for exotic tree and herbaceous Ferns, which are both numerous and excellent. For Filmy Ferns the gold medal goes to M. de Smet, who also secures the first-prize silver-gilt medal for hardy Ferns. M. Ghellinck de Walle contributes a fine collection of *Aroids*, for which he receives a silver-gilt medal.

Azalea indicas.—These are magnificent. Nothing in the Exhibition is more imposing than the gorgeous specimens of M. Ghellinck de Walle, who is awarded *à l'unanimité* the gold medal provided by the King for fifty plants. The most skilful and finished culture is exemplified in these grand umbrella-shaped plants. The heads, which are from 6 to 9 feet across, are as true as if cast in moulds, and are densely crowded with fine flowers in nearly all colours in which *Azaleas* are represented. The great gold medal for forty plants is also awarded to the same exhibitor, and the gold medal to M. Beaucarne. In the nurserymen's classes MM. Jean Vervaene and Joseph Vervaene receive gold medals for forty plants, and besides M. Van Houtte already named, prizes are won, and well won, by MM. Vandercruyssen, Boelens, and De Schryver. In the class for novelties effected by grafting, M. D. Vervaene contributes a remarkable collection than which few exhibits more forcibly attract the attention of English visitors. So skilfully have the heads of these plants been grafted that they represent concentric lines of colour as clearly defined as if the flowers had been cut and packed together in cones of moist sand. The colours are associated also with great taste. Mr. Vervaene receives the first prize in this striking class, followed by MM. Vandercruyssen, De Schryver, and Jacques Van Eckhaute in the order named.

Hardy *Azaleas*, especially varieties of *A. mollis*, attract great attention. Mr. Van Houtte exhibits many excellent varieties, but the prizes in the classes go to MM. De Smet, A. Verschaffelt, and C. Vuylsteke. The plants are extremely floriferous, and the colours are very varied.

Camellias are not generally so remarkable as the *Azaleas*, although many fine plants are exhibited. The gold medal for forty plants is secured by M. Van Eckhaute with fine examples of culture, a similar award being made to M. J. De Coster of Melle, for twenty-five plants. M. Linden receives a silver-gilt medal in the class for novelties in grafted plants, a similar award being made to M. Vercauteren of Melle for a new variety raised from seed in Europe. Mr. L. Van Eckhaute receives the silver-gilt medal for a plant remarkable for grand culture and free flowering. Several minor prizes are awarded in these classes.

Rhododendrons are gay, and some of the new varieties exhibited are very good, but on the whole they are not equal to the plants produced by the chief English growers. Greenhouse and Cape plants are not grown on the Continent so well as in England, and Messrs. Rollisson had little difficulty in winning the gold medal for fifty plants in flower in this section. The same firm also won chief honours in the class for *Anætochilus* and *Goodyeras*. Flowering decorative and market plants are not equal to those produced by the English growers for Covent Garden; but *Yuccas*, *Agaves*, *Dasylirions*, &c., were admirably represented by many exhibitors. *Myrtles*, *Aucubas*, miniature *Oranges*, &c., are noticeable; plants of the latter not much more than a foot in height are covered with fruit.

Having now glanced at the classes in which our readers will be chiefly interested, we will briefly describe the character of the Exhibition as arranged in the casino and supplementary structures. The rotunda is an immense hall; in the centre is an oval-shaped bed 120 feet in circumference, composed of the grand *Azaleas* of M. Ghellinck de Walle and Comte de Kerchove de Denterghem. Near the ends of the hall are two smaller round beds of *Azaleas*, a *Palm* occupying the centre of each bed. Four very large pear-shaped beds—the points approaching the central bed and the broad ends the four corners of the hall—are occupied with mixed collections from various exhibitors. Mr. Wills' *Dracenas* and *Nepenthes* fill the greater portion of one of these beds, the remaining portion being occupied with the Comte de Kerchove's excellent *Selaginellas*. Another of the beds is filled with Ferns from the same nobleman and *Azaleas* from M. Vervaene; a third bed with *Azaleas*, Ferns, and flowering shrubs; and the fourth with *Crotons*, *Dieffenbachias*, *Marantas*, *Anthuriums*, *Azaleas*,

&c., from MM. Van Houtte and Vervaene, also groups of *Zamias* and *Rhododendrons*. Another bed near the end of the hall contains a grand example of *Cibotium regale*, and under the shade of its ample fronds are *Marantas* from M. Van Houtte, *Crotons* from M. Ad. d'Haene, and *Ferns* from the President. On one side of the hall at the base of the balcony platform is a very large semi-circular bed, with a great collection of plants from M. Van Houtte—*Rhododendrons*, *Magnolias*, *Ericas*, *Caladiums*, and other fine-foliaged plants; also *Palms* from M. d'Haene. On the opposite side a great collection of *Tree* and other *Ferns* and *Palms* from M. Ghellinck de Walle has an imposing effect. An undulating border is formed along one side and end of the building, and groups of flowering plants, such as *Camellias*, *Azaleas*, *Rhododendrons*, &c., also *Palms* and fine-foliaged plants, are arranged, the other end opening to the annexe. Sufficient space is provided for the convenience of visitors, and the plants are disposed in the most convenient manner for inspection. The effect of this hall, and especially when viewed from the balcony—the gorgeous masses of colour being relieved by the ample fronds of *Palms*, &c.—is highly imposing. It is an exhibition of itself worth crossing the Channel in a storm to see, yet it is only a portion of the aggregate display.

Let us next step upstairs. At the top of the staircase we observe a collection of plants from Mr. Bull, amongst which plants of the *Siberian Coffee* attract the attention of admirers of economic plants. In contrast is a group of the distinct *Dracæna Goldiana*, also *Dieffenbachias Edgworthii*, *Leopoldi*, and *reginæ*, exhibited in Belgium for the first time and much admired. Mr. Bull also exhibits *Anthurium Veitchii*, *Lomaria discolor bipinnatifida*, and a group of new *Aralias*, a fine *Palm Martinezia Roezlii*, &c., and the rare *Palm Pritchardia grandis*. M. Linden's collection contiguous contained striking examples of *Anthurium crystallinum longifolium* and *A. Dechardi*, *Aralia elegantissima*, *Tillandsias* of great promise—*Massangea Lindenii*, *M. Lindenii* var., and *M. Lindenii* variegata, a trio of very beautiful *Bromeliads*, which will be heard of again. M. Linden also exhibits new *Palms Pritchardias aurea* and *macrocarpa*, *Kentia Lucynana*, *K. Lindenii*, &c. We next come to fine collections from M.M. Van Geert and Van Houtte, amongst which a splendid group of *Bertolonias* from the latter named exhibitor are regarded as the gems of the Exhibition on account of their varied and glowing colours. These plants are noteworthy as having been raised in M. Van Houtte's establishment by the skilful hybridist M. Van Eckhaute. It is in this section of the building that the plants are arranged in competition for the cups offered by Mr. Bull. Near them and in admirable contrast is a group of tuberous *Begonias* in flower. The new glazed hall or conservatory—a splendid building—is also occupied with splendid plants, ornamental-foliaged plants and grand *Azaleas*, marvellous by their beauty and culture. The general effect of this building is extremely rich.

There is yet another very large temporary building occupied with plants. At the end opposite the entrance of this roomy structure is M. Hoecke Peeter's stalactite grotto skilfully arranged. A waved border quite filled with plants, the groups of thirty exhibitors, nearly surrounds the building. A walk is formed down the centre, on both sides of which are arranged two irregular rows of isolated beds, some of them being very large. These seven beds present an imposing appearance. A bed near the centre contains Messrs. Rollison's collection of greenhouse plants, also *Agaves* and *Araucarias*; another is filled chiefly with *Rhododendrons*, and the others with flowering and foliage plants from about twenty exhibitors, for in Belgium all the plants are arranged for effect after they have been judged.

Still other structures contain plants; but we have said sufficient to show that the Exhibition is one of great magnitude, and we trust that it will prove as successful to its promoters, and to those who have aided in producing it, as the great efforts made demand that it should be. Such occasions enable the floral resources of nations being seen at a glance, provide the means for old international friendships being strengthened and new associations formed, give an important impetus to horticultural commerce, stimulate to further effort, and sow the seeds of future and greater gatherings and greater successes. To our Belgian friends we offer English congratulations, and we appreciate all the endeavours they have made, and made successfully, to render a visit to their shores so pleasurable and instructive.

ROYAL HORTICULTURAL SOCIETY.

APRIL 2ND.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Although most of the chief nurserymen are sustaining the honour of British horticulture at the great Ghent Exhibition, there were sufficient plants left at home to make a very attractive display in the conservatory. To this result the late adverse weather had, contrary to the usual order of things, to a great extent contributed, for had it not been for the extraordinary storms of last week the following fine Orchids from the nurseries of Messrs. Veitch would have been arranged in the Casino at Ghent instead of in the con-

servatory at South Kensington:—*Cypripediums selligerum*, *Argus*, *Harrisianum*, *Haynaldianum*, *Schlimii album*, *Dayanum*, *villosum*, and *Lowii*; *Dendrobiums crassinode Barberianum*, *Wardianum*, *Wardianum album*, *macrophyllum giganteum*, *chrysotum*, *Cambridgeanum*, and *Devonianum*; *Lycastes Skinneri* and *Skinneri alba*; *Masdevallias Lindenii*, *Veitchiana*, and *igneæ*; *Odontoglossums Rossii majus*, *Roezlii album*, *luteo-purpureum*, *prænitens*, *gloriosum*, *cirrhosum*, *cordatum*, *Cervantesii*, *Alexandra*, *Pescatorei*, *Halli*, *Andersonianum*, *triumphans*, *Roezlii*, and *roseum*; *Oncidium concolor*, *Forbesii*, *Marshalli*, *sarcodes*, *fuscatum*, and *leucochilum*; *Stenia fimbriata*; *Lælia Pilcheriana*; *Vandas cristata*, *suavis*, *meleagris*, and *tricolor*; *Ada aurantiaca*, *Bollea Lalindei*, *Cattleya citrina*, *Cymbidium eburneum*, *Aerides Fieldingii*, and *Phalenopsis Schilleriana*; *Anthurium Scherzerianum*, fine var.; *Sarmienta repens*, and *Imantophyllum miniatum superbum*. A group of *Amaryllis*, including the following named varieties:—*Brilliant*, *Miranda*, *Junius*, *Olio*, *Sir Trevor Lawrence*, *Phædra*, *Bismarck*, *Mrs. Speed*, and *Haydn*. Six named *Gloxinias*—*Vesuvius*, *Duchess of Teck*, *Duchess of Edinburgh*, *Sir Stafford Northcote*, *Pageant*, and *Lord Derby*. A group of *Roses*. Such an array of Orchids with *Gloxinias* in variety, *Palms*, *Amaryllises*, and upwards of sixty *Roses* in pots constituted an extremely fine display. In this collection was also exhibited the very rare and almost extinct Gesneriaceous plant *Sarmienta repens*, which was introduced from Chili many years ago. It inhabits very moist places, and is covered with brilliant scarlet flowers. A gold Banksian medal was recommended for this collection.

Mr. B. S. Williams, Victoria and Paradise Nurseries, Holloway, sent a varied and excellent collection, consisting of well-grown Orchids, *Amaryllises*, *Ferns*, and ornamental-foliaged plants, to which a silver flora medal was awarded. A botanical commendation was also awarded to Mr. Williams for *Masdevallia radiosa*, which was very curious. Mr. J. Aldous staged an artistic group of fine-foliaged and flowering plants, and a silver flora medal was also awarded. Sixty pots of *Cinerarias* were exhibited by Mr. J. Levesley, Spring Grove Lodge, Isleworth. The plants were particularly dwarf in habit, not exceeding 8 inches in height, and were in 48-sized pots. Mr. Levesley also sent a small group of *Cyclamens* and *Polyanthuses*, which received a bronze Banksian medal. Messrs. Osborn & Sons arranged an admirable group of fine-foliaged and flowering plants, and were awarded a silver flora medal. From Messrs. Barr & Sugden, Covent Garden, came an extensive and highly attractive collection of *Narcissuses*, and were awarded a silver medal. A silver Banksian medal was given to Mr. Heims, gardener to F. Philbrick, Esq., Q.C., Regent's Park, for a very choice collection of Orchids, principally *Odontoglossums*, with a very fine plant of *Cattleya citrina* in the centre of the group.

Prizes were offered at this meeting by an amateur for seedling *Amaryllises*, the first prize going to Mr. F. Knowles, gardener to H. Little, Esq., Hillingdon Place, Hillingdon, for a very dark flower named *Crimson Banner*, which variety was also awarded a first-class certificate; the second prize was awarded to Mr. B. S. Williams for Dr. Hogg, a large and showy pale scarlet flower of excellent form and substance.

Some very fine flowers of *Crinum pedunculatum* came from Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingly, which received a vote of thanks. A similar award was made to Sir C. W. Strickland, Bart., Hildenly, Malton, for *Crinum campanulatum*. To Mr. R. Dean, Ealing, a first-class certificate was awarded for *Primrose Prince Charming*, crimson striped with white; it was indeed a charming variety. Mr. Dean also received a vote of thanks for seedling varieties of *Primula intermedia*; and Mr. Cannell, Swanley, Kent, was highly commended for boxes of cut flowers of *White Vesuvius*, *Striped Vesuvius*, and *Salmon Vesuvius* *Geraniums*, and a stand of twenty-four distinct varieties. From Mr. W. Chitty came a basket of *Narcissus Bulbocodium*, which also received the thanks of the Committee.

THE FRUIT COMMITTEE had no duty to perform except awarding a vote of thanks to Mr. Joshua Atkins, gardener to Col. Lloyd Lindsay, Lockinge Park, Wantage, for very fine bunches of *Black Alicante Grapes* which had been kept in remarkably good condition. A dish of lily white *Seakale* was sent from the Society's garden at Chiswick. A cultural commendation was awarded to Mr. M. McLean, The Gardens, Linton Park, Maidstone, for a beautiful collection of *Variegated Greens*, some of which were very striking.

NEW BOOK.

Roses and their Culture. By W. D. PRIOR, with numerous Woodcuts and Coloured Illustrations. G. Routledge and Sons, London.

THE following extract from the preface is a true representation of the contents:—

"The following little treatise begins at the beginning. The arrangement followed is that of first presenting a general view of the subject, and afterwards proceeding to details of practical culture. The instructions laid down are the result of many years'

experience (sometimes under no small difficulties) as an amateur, corroborated by intimate acquaintance with the routine pursued at some of the most celebrated Rose nurseries, the proprietors of which the writer has the happiness to number amongst his personal friends. Nothing, therefore, laid down in the following pages is the result of mere speculation or transcription from other books."

The "coloured illustrations" are the worst we have ever seen.

PARAFFIN STOVES VERSUS FLUES.

"A. C.'s" experience as detailed on page 203 of the Journal came too late to help me, but I am not the less thankful for his communication, as also for that of a previous correspondent. Who amongst your poorer readers is not tantalised by being instructed "to sow this or that in heat," "to strike cuttings in bottom heat," &c., when in the poverty of their gardening apparatus they might as well be told to take the moon in their arms or walk head downwards? Such instructions may be just suitable to the rich or the large gardens of those who can command any resources, but for the amateur or small gardener they are simply useless.

But the want of appliances often teaches us to discover simple and cheap means to attain our ends. Finding no direct response to my application on page 92 I determined to experiment for myself. I procured for 1s. 9d. a common paraffin lamp and glass. I made a radiator by cutting slits in an old 6 lb. Australian meat tin, and placed it at the open end downwards on my lamp. I put it into a small closet and found I could get any heat I liked up to 80°. Here was a discovery. Thereupon I had a tinsmith to make me a cylinder 12 inches high by 6 in diameter as figured at B, a wire handle

Fig. 38.—Paraffin stove.

- A, an ordinary half-inch single-wick common lamp (mine is one of Hinks & Son's).
 B, a tin radiator or cylinder, with air holes top and bottom.
 C, a wire handle with a wooden centre.
 D, the cylinder is open, so that it can be placed over the lamp.

at C, and open at the bottom at D. The top of the cylinder had twelve holes punched in it half an inch in diameter, and at the foot twelve slits were cut to admit air. I placed my lamp in a Cucumber frame 8 feet by 4, and when lighted I put the cylinder C B D over it and let the handle C fall to the side. The lamp will burn thirty-six hours without refilling, but I find it best to fill up once in twenty-four hours. The cost per twenty-four hours is rather more than a farthing, as the paraffin costs 1s. 2d. per gallon. I can, with the outside temperature at 50°, raise that of the frame from 60° to 80° at pleasure; and this day, with the glass at 33°, my frame is enjoying 55°, and I could have more heat if I choose to turn up the wick.

There is neither smell nor smoke. No attention is required beyond filling the reservoir and cutting off the dead wick twice a week or so, and though I am only trying it to-day with a delicate Fern inside the frame, I am quite confident it will not be injured any more than the *Lobelia*, *Ageratum*, *Zinnia*, &c., now coming forward in my seed bed under heat with 60° to 65°! Probably Hinks or Ripplingill or some other lamp-maker will take the hint and make a stove for 2s. 6d. or 3s., which they can easily do, for the million, for very sure I am that whilst many must have longed for heat, their pockets have softly sung to them the refrain of "Not for Joseph, oh,

no, no." With the severe frosts daily this week I have had my experimental frame heated from 48° to 55° night and day; once every day for a few minutes sufficing to trim and refill the lamp.—E. H.

JUDGING ROSES.

SURELY nothing was ever devised more inconvenient to Rose-growers than the present rules as to the time of judging Roses at the various exhibitions. By nine o'clock each exhibitor must have entered the show, and by 10.30 he must have staged his blooms. Now what does this mean to the majority of exhibitors? It means cutting your blooms thirty-six hours before they are judged. Consequently it ensues that numbers of blooms upon which we depended for our success have lost their freshness, and are *parade* and almost worthless. These have to be replaced by spare blooms, which we cut when little advanced beyond infancy or little better than buds, and the chances are very great that these blooms are often very mediocre to say the least, as it is impossible always to tell what a bloom will be when in the bud.

But what remedy is possible? What course do I recommend which will be an improvement upon the present system? Well, I have an idea, but it is borrowed—in fact it is a still-born plan of Mr. George Paul's. Some years ago that famous rosarian propounded a plan to two or three leading rosarians which, if adopted, would prove a complete remedy for all the drawbacks above stated. This was that our show should open, not at one as now to the public, but at five or six. This would enable rosarians at a distance to cut and bring their blooms the morning of the show by the first train, and have them ready for the judges by three or four o'clock. The show would then be kept open till ten o'clock, and perhaps might attract numbers of business men and others who cannot attend under the present system without sacrificing valuable time.

Several rosarians to whom this idea was divulged approved of the plan and promised to support it; but if I remember right someone who never shows opposed the idea, and nothing came of it. But the idea is, in my opinion, so good that I thought I would ask your permission to ventilate it in the Rose Journal, and perhaps something may come of it.

It is obvious that growers in the far west and north show under great disadvantages, and are, so to speak, severely handicapped in the contest for fame and honour at Flora's court; while men who live within a few miles of the metropolis have everything in their favour, unless we except perhaps climate, which is about equal. A man who can cut his blooms about three o'clock on the morning of the show and place them on a cart and convey them direct to the Crystal Palace, has an immense advantage over the man who cuts at three o'clock the previous morning and has to convey these blooms first to the station in the heat of the day, then have a long journey to town, and it may be have to move his boxes from train to train, and when he arrives in London has once more to put them upon a conveyance and drive to Sydenham. But some such plan as that I have named would at least give the countryman a little more time and make the odds not quite so many against him.

It is a perfect marvel to me how blooms do stand the knocking about; but all depends upon their strength and substance. I do not think a more extraordinary instance of the strength, and endurance, and longevity of a Rose bloom can be adduced than the following, but if there is I should like to hear of it. I can vouch for the facts.

Mr. Baker had a marvellous bloom of Marie Baumann out on the Sunday before the Crystal Palace Show. He called his wife out of the house, "Do come and look at this Marie Baumann, I do not think I ever saw a finer bloom." He showed that bloom on Thursday and Friday (a two-days show that year) at Exeter. His boxes were then taken home, and the bloom being still good he took it to the Crystal Palace, where it formed one of the forty-eight which won the first prize, and before he left the Palace he went to look at his box to see if Marie Baumann was still alive, and she was not only alive but kicking—i.e., as good as ever. I believe the bloom was sold for half a crown by the gardener, and taken home by some enthusiastic rosarian, who had it blooming on his table for another week; but I am not sure of this, so cannot "paint the Lily" and adorn the tale with what I cannot vouch for.

But this is a case which could only occur, perhaps, once in a lifetime. The weather at the Exeter Show was vile—rain all the day, so the atmosphere in the tent was as cool and

nearly as dark as in a cellar, and the time of year was the early part of June before the sun's rays became so fierce as in July.

And now I come to a matter upon which I should like to have the opinion of my Rose brethren, and that is the important matter of water. What kind of water shall we fill the tubes with? Is it to be cold spring or pump water, or rain water? or shall we do what a colonel of a cavalry regiment once ordered the son of a famous confectioner to try on a restive horse, "ice it?" My friend Canon Hole in his book upon Roses recommends (if my memory does not mislead me) rain water, others (myself included) spring water, while two great rosarians have tried with the greatest success ice water. Mr. Cant tells me that he iced the water in which his Rose blooms were placed that he took to Scotland, and he was astonished how much fresher they were than those of his great rival who had come an equal distance. Mr. Baker used melted ice for his National blooms, but he is a little doubtful about it; and an equally excellent rosarian, the lady who presides over the Heavtree dinner table, thinks that it was a mistake. She inclines to the idea that the ice prevents the blooms opening, which undoubtedly it does, and which is the intention; but for such a journey as from Exeter to London with such stuff as the Heavtree Roses consist of she holds that it is wrong. What say other great authorities? I have not yet tried it, but am inclined to go with Mr. Cant.

I think I have opened two subjects of great interest to your readers, and if the discussion that this article evokes is in any degree proportionate to that of my letter on Rose-judging the result will, I hope, be as satisfactory to your subscribers as it will be to a—WYLD SAVAGE.

I HAVE attentively perused the correspondence about judging in the *Journal of Horticulture*, and agree with all Mr. Baker says on the subject.

Most rosarians agree that form, colour, and size should stand in the order written.

A judge should certainly be a successful exhibitor, not *have been*, for he should be conversant with the new varieties.

I think point cards should only be used as a *dernier ressort*, for that method of determining the comparative merits of stands takes no account of evenness—a very important feature in my opinion, neither of arrangement of colour, another point of considerable importance.

I am inclined to think Teas and even such Hybrid Perpetuals as Madame Furtado, Marquise de Mortemart, &c., should have extra points. I am always puzzled both in exhibiting and judging when Teas and Hybrid Perpetuals are juxtaposed. No doubt a few of the former greatly enhance the beauty of a stand, yet they seem so distinct from the more masculine Hybrid Perpetuals that to compare them is like attempting to decide if Adonis or Venus be the more beautiful.

I should like to see amateurs and nurserymen set to adjudicate the exhibits of their respective classes. I mean amateurs to judge the Roses of amateurs, and nurserymen those of nurserymen; but that, as a secretary, I know cannot well be.

Let there be three judges to a class if possible, never one. I never was dissatisfied with an award except once, when a solitary judge put my box second because I had placed in it what I thought a fine bloom of Madame Lacharme. He did not like the Rose. He, however, placed me first for Teas when I should have been second.

On the whole I am disposed to think no satisfactory rules can be drawn up for the guidance of judges. I call to mind, however, how little a really good "all round" gardener often knows about Roses. Such a man might be grateful for rules.—HUBERT BENSTED.

PRUNING PEAR TREES.

No doubt, as is suggested by "A COUNTRY PARSON" on page 247, that some varieties of Pears produce fruit buds on the young wood, and especially at the "ends of the shoots," more freely and quickly than do others; but I have never yet seen a Pear that will not form natural spurs if it is permitted to do so.

Your correspondent has rightly remarked on the tendency of that valuable late Pear *Joséphine de Malines* to produce fruit buds at the extremities of the shoots, which shoots are frequently cut off, causing direct loss of fruit. The same remark applies with equal force to one of the most delicious of autumn Pears, *Marie Louise*. Those, and some other varieties

that might be quoted, show in a very marked manner the errors of the system of pruning that is now pretty general, so far at least as regards the production of full crops of fruit. If a dwarfed tree of rigid symmetrical outline is of more moment than a large supply of fruit, then close pruning of roots and branches must be adopted; but if the main object of growing trees is the production of fruit, then I assert that the fancy pruning now so common is fallacious.

I am well aware that there are positions by the sides of walks in gardens where it is necessary to restrict the growth of trees to a prescribed standard, and when such trees are well managed they produce fruit freely. I have adopted that mode of fruit culture; indeed, had I not practised that and other systems of management I should not have ventured to write on the subject. I do not object to close pruning when circumstances demand it provided the work is rightly done; but what I object to is the unintelligent way in which I am obliged to see trees treated by letting them grow thickets of shoots 2 feet long in the summer, and shortening the laterals to 1 or 2 inches and the terminals to about 6 inches in the winter, while the roots remain untouched. That is the way in which thousands of trees are managed—extension in the summer and restriction in the winter, and both with a vengeance. I agree entirely with what "A MIDLAND COUNTIES FRUIT-GROWER" has written upon this subject. There is too much summer growth permitted and winter cutting indulged in; and the result is, taking the country through, that hundreds of tons of fruit are wasted—i.e., prevented forming on the trees.

If summer growth is permitted and a large return of fruit is required the rational plan is to thin out a sufficient number of branches, so that the sun can shine through the trees, not in winter only but in summer, and do very little in the way of shortening the branches remaining, and shortly the trees will be studded with fruit spurs. That is what very extensive observation and several years of experience have taught me; and I have further found and observed that trees thus managed are, so far as appearance goes, far more often handsome in shape than unsightly.

It has been my duty to grow fruit trees on the restricting system, and I remember about eight years ago planting a tree of Williams' Bon Chrétien Pear to fill up a vacancy, and the tree had to be pruned in the same manner as the others in the garden. At the same time I purchased a tree of the same size for a cottager. Both trees were planted in the same week. My tree has been pruned regularly and has produced good crops of fruit; the cottager's tree has not been pruned at all, unless the removal of a stray branch growing across the others can be called pruning, and I am quite certain that the unpruned tree has produced as many bushels of fruit as the pruned tree has yielded pecks. I grant that the fruit from the restricted tree has been finer than that of the naturally grown example, otherwise I should feel much humiliated; yet nevertheless the produce of the cottager is sufficiently fine to be eagerly purchased by the fruiterers of the adjacent town.

Two years ago my attention was directed to some very old *Marie Louise* Pear trees trained to a wall. They had produced luxuriant breastwood for years, which was duly spurred-in during the winter, but they produced scarcely any blossom. They were indeed regarded as hopelessly barren—worn out. On pointing out to the owner that by cutting off the young wood he had prevented the formation of fruit spurs, he took me aback by saying he would not prune the trees any more: he cared nothing about looks, but wanted fruit. The trees were left unpruned in all their slovenliness, and now they are studded with thousands of fruit buds. Sturdy branches have grown 3 feet above the top of the wall and will soon be as "white as a sheet" with blossom. Weather permitting more fruit will be gathered from the trees next autumn than has been produced by the trees for the past ten years. This example of management or neglect is not suggested as worthy of imitation, but is simply adduced as illustrative of the error of letting summer growth extend for the purpose of shortening it in the winter—one long course of irrational routine, as hacking as it is hacking—a fruitless round.

When trees are planted for the purpose of producing maximum crops of fruit in a minimum amount of time let Nature preponderate over Art in their management. Art may prepare the soil by draining it when necessary and otherwise rendering it fertile, and also may aid in admitting the sun to the foliage by thinning out superfluous growth. Nature then will have fair play; she will be assisted, not obstructed, and fruit buds are as certain to follow as day follows night.

Trees thus managed are those that will supply large families and markets with useful fruit. It is the system,* too, that should be advocated for cottage gardens, where the philosophy of pruning is necessarily not understood, and more real benefit would result than by encouraging the adoption of the pretty dwarfing system where it cannot be carried out profitably.

One of the wants of England at the present time is more fruit—useful home-grown fruit, and one of the most certain ways of attaining it is, in my opinion, to be found in less pruning.—J. W.

AURICULAS.

If this cycle of mild winters and cold and severe springs continue a change must come "o'er the spirit of our dream" in many ways. All hope of growing Peaches, Apricots, and Nectarines on unsheltered walls must be abandoned, and even the florist will have to reconsider his ways. In common with many of the older florists I have all along deprecated the use of fire heat for Auriculas; but when such experienced growers as Messrs. Horner, Booth, Woodhead, Simonite, and others assure us that not only does it not injure them but that they thrive under it, it would be idle to put past experience in the scales against present necessity; and when one looks abroad on this April-fools' day and sees fully 4 inches of snow on the ground and marks that in the shade at 10 o'clock A.M. it is freezing hard, it is clear that a revolution has taken place, and we must adapt ourselves to these altered circumstances.

In looking back a few years I can remember seasons within the last ten years when the greater number of my plants were over by the middle of April, but that, as a general rule, from the 18th to the 21st of April they were about at their best; and when the proposition to hold a National Auricula Show was made some years ago, the great difficulty was to fix a time sufficiently late for the southern growers to have anything like a fair chance with the northerners, and when the 30th of April was ultimately fixed it was found that the former were at a great disadvantage. Now the Northern Auricula Show has been fixed for that very date, and the Southern one for only four days before it, and we may expect to see many of the northern growers at the Crystal Palace. I am writing down mainly from the exhibition point of view, for I have no doubt that whatever may be the altered character of our springs, the flowers would not be injured where care was taken to cover the frames well, much less where they are grown in pits where they are more easily protected, and even without protection warmer than in frames.

In one respect I am sorry for this, for if the Auricula must be considered a greenhouse flower as far as exhibition purposes are concerned, the smaller, and I may add the poorer growers, must be distanced by the wealthier. It is not everyone that can afford to build a pit and heat it, and if the exhibition of last year is to be taken as a criterion it is clear that those who have used fire heat will be the prizetakers.

The present season is, I am convinced, as late a one as last year if not later, and this judgment is not formed from the state of my own collection, but those of several friends who are Auricula growers; of my own I say nothing. The double potting produced the results that one fairly anticipated, and has both made them very late and diminished the size of the trusses; for the second potting had to be done before the heart was formed, and consequently at a time when the energies of the plants ought to have been thrown into the formation of fresh leaves and the truss. They had to be divided between that and the making of fresh roots; for it was not like simply repotting into a larger pot, where a ball may be left with a certain number of roots, which had only to emit fresh rootlets, but every atom of root had to be cleaned or washed, and thus great stress was laid upon the power of the plant.

We shall hope to see a fine collection of plants at the Crystal Palace, more exhibitors I hope, and a wider interest taken in this lovely flower.—D., Deal.

ODDS AND ENDS.

In my early days scarlet *Lychnis* was popularly called Bridget in her Bravery. This name no doubt was given because it is in flower in July, and St. Bridget was commemorated on July 23rd.

Dianthus barbatus, now commonly called Sweet William, was, and still is sometimes, called London Tuft. The Wall-flower again was called Sweet William, and the name is not

yet obsolete. The 25th of June is the day that was dedicated to St. William.

Devil's Guts was a vulgar name for Bindweed (*Convolvulus arvensis*), expressive of the detestation in which it was held by rustics.

Fox-poison was the popular name for the Spurge Laurel.

Southernwood was and is still called Lad's Love.

Arum maculatum is known as Lords and Ladies. I believe it to be a far-fetched conceit that this name was given to it because lords and ladies had their ruffles stiffened with starch made from this plant.

The popular name of *Ranunculus arvensis* (Corn Crowfoot) is Pickpocket, marking it as injurious to farmers.

The Yew was formerly called Vew, but the word is going out of use.

Hylla (Danish *Hyldre*) was the name for Elder.

Prime is still used for Privet, and Ivin for Ivy.

The young shoots of the Briar when peeled were called Sweet Briar and eaten.

The young leaves of the Whitethorn are eaten by children and called Bread and Cheese.

Parsley has a mystery attached to it. The cause of the seed lying so long in the ground is that it goes to the infernal regions and back three times before it comes up. Any person transplanting a root of Parsley is said by the superstitious to be sure to die within the year.—A LINCOLNSHIRE COUNTRY VICAR.

PHEASANTS AND CROCUSES.

MR. HANBURY of The Poles, a place I remember to have seen described in the Journal, wrote lately that the pheasants about his place devoured the yellow Crocuses, but left those of another colour, and wished to know if others had observed a similar occurrence. I have for many years in succession. I planted a long ribbon border of yellow, blue, and white Crocuses. Something seemed to attack the yellow strip, which the gardener thought must be slugs or sparrows. One day I and several friends watched out of the window the amusements of three pheasant cocks within a few yards' distance. They commenced at the top of the border and took the yellow row before them, but never meddled with the others. What connection exists between colour and taste for these birds I cannot say, but there must be some, otherwise it would not take place season after season. Some clever man recommends dipping the bulbs in paraffin. This has nothing to do with it. It was the bud and flower which they ate, not the bulb at all.

The black grouse or black game have a similar taste. When I rented a moor on the Northumberland border I and my guests, when changing for dinner, observed that a fine lot of black cocks came every evening to a field opposite the windows, and were evidently feeding on something. The said field was wretchedly poor and exhausted, having been ploughed and no management given it afterwards; in short, three parts out of four were bare soil. I sent my lad, who crawled behind a wall and shot one with a pea rifle. We had an M.D. in company who was a great anatomist, and we opened its crop directly. The contents consisted of flowers of several of the Hawkbits, Hawkweeds, and other yellow flowers; but all yellow.

At this moment I have a tame black cock. It came here shortly after harvest, and is evidently an escaped hand-reared bird, as their nearest habitat is the Scotch border thirty miles distant, and it associated with the domestic fowl immediately. It has become perfectly troublesome, and has driven all the tame pheasant cocks from the lawns and pleasure grounds. This bird never leaves the house far, and I have observed, and so has the old gardener, that it snaps off and eagerly devours the flowers and buds of the Coltsfoot as fast as they appear, also a flower called *Doronicum*. A year or two since I noticed a peculiar chirp of some bird which was not familiar to me. It perched within a yard or so as I was sitting near a fountain. It was the blackcap warbler (*Syl. atricapilla*). I find it recorded only once before in Cumberland. Yarrel, in his account of it, says that it prefers red fruit. A day or two afterwards my gardener, while taking his usual respite after dinner, saw the hen bird and several young ones sitting on a rail which supported some Currant bushes. He watched them a long time, being a bird fancier, and told me that the mother in every instance brought and fed them with a red Currant or red Raspberry, but never a white one, though both sorts were growing close to each other, and each equally ripe. I was in hopes that this pair would return next

season, as some of our books say they do, but we have not seen them since.—J. GILLBANKS.

OUR BORDER FLOWERS—RUEWORTS.

THE Fraxinellas at first sight give us the impression that we are looking on some diminutive variety of Fraxinus, so much do the leaves of the two resemble each other; to that circumstance is attributed the name Fraxinella, by which this fine old occupant of our borders used to be known. It is also called by the name of Dittany or Dictamnus rubra. By whatever name it is known there can be but one opinion respecting its merits as a border flower; the least that can be said of it is that it ought to have a very prominent place in every herbaceous border and in all cottage gardens. Perhaps it is one of the oldest of our border flowers, and at the same time one of the most neglected. When once thoroughly established and left alone it lasts for a lifetime. The white variety does not appear to have the robust habit of *D. rubra*, but its beautiful flowers make up for other deficiencies.

There is some difficulty in increasing these plants; it can be done by division, but requires skill and patience, as they do not produce many side shoots; they are also increased by seed sown as soon as ripe in the light, rich, well-drained soil of a sheltered border, but the seed does not always vegetate, from what cause I am unable to say. Sometimes the seedlings do not make their appearance until the second year. They thrive in good, sound, sandy loam; they are impatient of too much wet, and require efficient drainage. The strongest plants I have met with are growing in limestone districts, some of them having attained to the dimensions of moderate-sized Gooseberry bushes, but such plants are few and far between. They are suitable for open spaces in the shrubbery and for the centres of beds where herbaceous plants are cherished. The Fraxinellas are amongst the choicest and oldest of our old favourites.—VERTITAS.

KEW GARDENS.

LOCAL agitation for the earlier opening of Kew Gardens and making them primarily a rendezvous for general recreation has caused more of public attention than usual to be directed to them. Our own views of the question at issue have been stated plainly and clearly, and from the position we have taken we do not swerve.

We regard the Royal Botanic Garden at Kew as a national educational establishment formed for the promotion of botany, horticulture, and allied sciences, and for turning them to practical account both at home and in the colonies. That we regard as the primary object for which the gardens were and are established and supported. Holding those views we could not permit ourselves to be so far disloyal to the science with which we are identified, and to the great body of horticulturists that we share in representing, to give our acquiescence to a measure which essentially renders the principle of this great technical establishment subservient to the pleasures of the local community. We will not silently permit a change being made of so fundamental a character, nor allow the educational nature of the gardens to be made a secondary object. What we contend for is this—that the real and leading object for which the gardens were established shall be sustained in its integrity, and that local pleasure shall be subservient to national education, not national education to local pleasure.

We do not forget the gardens at Kew are supported from the national exchequer, and we recognise the equity that as the public pay for them they have a right to enjoy them. The public do enjoy them for as great a length of time as is compatible with the due performance of the real and important work of the establishment. If earlier admittance is conceded to the local public the work of the gardens, we have good reason for supposing, cannot be so well done as it is now, at any rate without involving a considerable increase of expenditure. And what does this mean? It simply means that the real public—the great body of taxpayers of the nation—shall pay more than they have hitherto done for the mere gratification of an infinitesimal section of the community who happen to reside in the vicinity of the gardens. We fail to recognise the justice of a change of that nature. If the agitation now in progress were a national one—if the majority of the taxpayers of the nation were desirous that the gardens be opened to the public earlier, and were willing to pay the additional sum that would be required for that privilege, then the question would be different. But the agitation is not a national

one; it is not even a metropolitan one. It is neither the public of Britain nor the citizens of London who are moving in the matter, but simply the residents of Kew and its neighbourhood. No doubt the petitions in large characters which have been adroitly spread at the metropolitan railway stations—Waterloo, for instance—have caught a certain number of signatures; but what do they represent? Simply that a certain number of people are desirous of enjoying as great amount of pleasure as possible for—nothing. Signatures by thousands could be obtained for the opening of the Crystal Palace on Sundays, especially if it was to be opened free of cost; also for entrance into the British Museum at all times, as well as other government establishments. But in all such establishments it is necessary to close the doors during certain days and hours in order that real and necessary work may be efficiently performed. If that was not done the places would lose their interest and depreciate in value. And so it would be with Kew Gardens; if the working of the establishment was impaired it would lose its value, and it would not be worthy of its name of a national garden. We cannot consent that the mere gratification of a very local and fragmentary portion of the community shall outweigh the important requirements of a nation, including its colonies, which the gardens of Kew were appointed to supply.

We are not surprised at the manner in which the agitation movement has been supported by the local press. Indeed the local press would have been disloyal to local interests had it taken an opposite course. Members of Parliament must also give attention to local interests, simply because they are generally pledged to do so. We neither blame the press nor the inhabitants for the course they have taken; but it is another thing altogether for the Government to sanction a radical change being made that would impair the horticultural, botanical, or scientific status of Kew, or which would increase its cost to the nation except by a national demand. As soon as we have authoritative assurance that the necessary work of the garden can be duly performed in consonance with earlier admittance being granted to the public we have not the slightest objection that the gates be opened even at six o'clock in the morning. The question resolves itself into one of duty *versus* pleasure, and we simply adhere to the principle of placing duty first.

A brief historic notice of Kew will not be inappropriate; we therefore extract the following from the twenty-seventh edition of the "Guide to Kew," written by the late Sir William J. Hooker:—

"About the middle of the seventeenth century the spot that now forms the Royal Gardens of Kew, together with a residence called Kew House, belonged to R. Bennett, Esq., whose daughter and heiress married Lord Capel. Kew House and Grounds then passed into the hands of Mr. Molyneux, who was secretary to King George II. when Prince of Wales, and who married Lady Elizabeth Capel. The Prince of Wales, who was son to George II. and father to George III., admiring the situation of Kew House took a long lease of it from the Capel family about the year 1730, and began to form the pleasure grounds, then containing about 270 acres. They were completed by his widow, Augusta, Princess Dowager of Wales, who delighted in superintending the improvements, then conducted upon a most extensive scale. The exotic department of this garden was commenced by the same Princess and much favoured by the Earl of Bute, about the middle of the eighteenth century. Many of the finest foreign trees were contributed by Archibald, Duke of Argyll (styled by Horace Walpole the Tree-monger), who sent them from his once richly stored garden at Whitton near Hounslow.

"About the year 1789 His Majesty George III. purchased Kew House, and Queen Charlotte evinced much interest in the increase of the collection of plants. Under such auspices, and aided by the enlightened patronage of Sir Joseph Banks, it was only to be expected that the gardens of Kew should become celebrated all over the world.

"The voyage of Capt. Cook and Sir Joseph Banks round the world; those of Capt. Flinders and Mr. Robert Brown (Botanicorum Princeps), and of Mr. Allan Cunningham to Australia; the expeditions of Bowie and Maasson respectively to Brazil and the Cape of Good Hope—all these enriched the gardens of Kew with the vegetable productions of the southern hemisphere to an extent unparalleled before; besides which, other collectors were employed during a long period in various countries, and the produce of their researches was deposited at Kew. On various occasions, especially during the life of King

George III., many houses, stoves, and pits were erected; but on the demise of that monarch and of Sir Joseph Banks, who died shortly after the King, the establishment suffered from want of royal and scientific encouragement. During the reigns of George IV. and William IV. the botanic gardens retrograded, and matters must have been much worse but for the able exertions of Mr. Aiton and of his foreman (the late Curator) Mr. John Smith, A.L.S. Throughout the country an opinion existed, which soon began to be loudly expressed, that either the gardens should be entirely abolished or placed upon a very different footing, and rendered available as a great popular yet scientific establishment for the advantage of the public.

"Government was, happily, ready to respond to this latter feeling, and in 1838 the Lords of Her Majesty's Treasury appointed a Committee to inquire into the management, condition, &c., of the Royal Botanic Gardens. The result was that in

May, 1840, a return was made to the House of Commons in the shape of a report by Dr. Lindley, who, at the desire of the Committee, had surveyed the gardens in conjunction with two well-known practical gardeners.

"Many useful suggestions offered by Dr. Lindley were acted upon, especially the following:—A national garden ought to be the centre round which all minor establishments of the same nature should be arranged; they should be all under the control of the chief of that garden, acting in concert with him, and through him with one another, reporting constantly their proceedings, explaining their wants, receiving their supplies, and aiding the mother country in everything that is useful in the vegetable kingdom. Medicine, commerce, agriculture, horticulture, and many valuable branches of manufacture would derive much benefit from the adoption of such a system. From a garden of this kind Government would be

Fig. 39.—THE PALM HOUSE.

able to obtain authentic and official information on points connected with the founding of new colonies. It would afford the plants there required without its being necessary as now to apply to the officers of private establishments for advice and assistance.

"The limit of the garden not being exactly defined where it met the precincts of the residence of the King of Hanover, permission was obtained to include within the botanic garden all the ground immediately about the conservatory and orangery, which greatly enhanced the beauty of the view and added between 3 and 4 acres. Soon after application was made to the Queen for a grant of land from the contiguous pleasure ground, which might afford the means of forming a pinetum (or a collection of plants of the Pine tribe) and of erecting a Palm stove or tropical house worthy of the place and the nation. Her Majesty was graciously pleased to permit a portion of the pleasure ground, comprising about 47 acres and including a piece of water, to be devoted to these purposes, and enclosed within a light wire fence, which now separates the botanic gardens from the pleasure ground.

"Again in the winter of 1846-7 orders were received for abolishing the royal kitchen and forcing gardens of Kew as such, and incorporating them with the botanic garden, thus adding 15 more acres to the scientific portion of the grounds (75 acres in all)."

Such is an outline history of the national garden of which the accompanying figure affords a familiar and characteristic representation. It is a noble garden replete with instruction, and it is also attractive and popular. The broad sweeping lawns, the fine trees, the shaded walks, the unique collections of plants and the flowers, combine to render it singularly enjoyable by the increasing thousands who visit it annually during the summer months. The great Palm house is an imposing structure and contains grand examples of tropical vegetation. The structure, which was completed in 1848, is 362 feet long, 100 feet wide in the centre, and 66 feet high; the wings being 50 feet wide and 30 feet high. The temperate house is still larger, and contains many grand specimens of Antipodean trees and Ferns in exuberant health. The houses of Orchids, Aroids, Ferns, Aquatics, &c., are richly stocked, and it is surprising how well the plants look considering the ever-flowing stream of visitors and consequent draughts from open doors to which the plants are exposed.

The grounds during the summer are brightened by flowers, but artistic carpet bedding is not indulged in, that fashionable feature of garden decoration being, and we think wisely, left to the fashionable parks. It would be out of keeping with the stately and diversified beauty of Kew. Of hardy border and rock plants there are excellent collections, which at all seasons of the year yield attraction or instruction, or both.

Considering the variety and quality of the contents of Kew and its many features of interest, there is no wonder that the gardens are popular, and it would be a source of perennial regret if their usefulness, which is the true source of their popularity, should be in any way impaired.

MR. WILLS' NURSERIES AT FULHAM AND ANERLEY.

FROM time to time brief allusions have been made to some speciality in these nurseries, also to some example of floral decoration arranged on a public or private occasion with plants mainly provided either at Fulham or Anerley. Anything like a general notice of the establishment has not, however, appeared in the Journal, and yet few if any nurseries can afford a better idea of the extent of what may be termed domestic floriculture as it is now established in this country.

In the arrangements at festal banquets, both public and private, plants and flowers have apparently become as essential as wines and music. Neither is this to be wondered at when it is considered that the gratification of the eye and the mind are at least as important as the gratification of the ear; hence floral decoration has become a necessity of the times, and the mode of carrying it out has become something more than a profession—an art.

Perhaps no one has done more to foster a taste for home and festival adornment by the employment of plants and flowers and other appropriate accessories to their artistic arrangement than the owner of these nurseries. Mr. Wills, by the exercise of true taste in the arrangements of plants, and by the extent of the decorations that he is daily entrusted with, may be said almost to have created a new industry. Domestic floral embellishment has, it is true, been indulged in for a considerable period, and has been ably carried out by nurserymen as a part of their business, but no one has made it a speciality of such magnitude as the "floral artist" of Onslow Crescent.

Onslow Crescent is the head quarters of Mr. Wills' business, and although glass structures of considerable extent are there provided they are chiefly as receiving houses. There a staff of decorators and bouquetists are continually employed in arranging and dispatching the consignments which arrive from Fulham and Anerley, which are sent not only for the embellishment of royal bouquets and charity dinners in London, but to the mansions of the opulent in various parts of the country. The numbers of plants and flowers employed are extraordinary, the bulk of them being grown at Fulham and Anerley, but it is necessary to supplement them by extensive purchases from other nurseries at home and abroad.

FULHAM.—This nursery is about two miles from Onslow Crescent, and at present is just beyond the brick-and-mortar boundary of the metropolis; but the colossal city is rapidly expanding, and in a few years the nursery instead of being in the country will be in the town. This is evident by the invasion of builders, which is ever in progress, and is apparently irresistible. The nursery is an enclosure of about four acres, a considerable portion of which is occupied by glass structures, the remaining grounds being devoted to flowers and a few vegetables. It may be a matter of surprise that Cabbages, &c., are grown here; but the fact is explainable. Mr. Wills has been a gardener and has a gardener's feelings and sympathies. In the commodious dwelling he offers a home for an octogenarian gardener who honoured the craft by a long life of excellent practice at Denbies. Mr. Drewett here enjoys his well-earned annuity, and amuses himself among the vegetables, thus occupying his time congenially and usefully. He is not an *employé*, but an extra official respected by all in the establishment.

There are about a dozen houses, most of them capacious lofty structures for affording convenience to the large Palms, Camellias, and other plants that are in requisition for decorative purposes. The entire area of glass is 50,000 feet. Perhaps the most interesting house at the present time is that devoted to Orchids. It may be termed a double lean-to, for a lofty wall running east and west has a range of glass on the south side for Orchids requiring heat, and another on the north side for cool Orchids. The southern division is filled with a large stock of fine plants of *Lælia purpurata*, *Phalænopsis Schilleriana*, *amabilis*, *Dendrobiums*, &c. *D. Wardianum* is largely grown. It is one of the most beautiful of Dendrobies, and its ready growth and free-flowering properties render it one of the most valuable for decorative purposes. The plants are mostly grown in

baskets. The house on the north side of the wall contains a remarkable collection of plants. The back wall, which is about 80 feet in length and 12 feet high, will shortly be covered with *Lapageria alba*. The plants were planted-out last year in prepared stations and have made excellent progress. The flowers that will be produced on this shaded north wall cannot fail to be of very great value. It is just the place for growing a supply of what certainly is one of the most charming flowers in cultivation, and if Messrs. Veitch had done nothing more than introduced *Lapageria rosea* and *alba* they would have deserved well of their country. Rough turfy loam and peat, a shaded position (but not overshadowed by other plants), and a cool house are the conditions under which *Lapagerias* flourish. The front of the house is occupied with Orchids. A shallow tank is formed as near to the glass as is convenient, and in the growing season it is kept replenished with water. In the stream are placed inverted flower pots, which rise an inch or two above the water, and on these pots the Orchids are arranged. They there grow luxuriantly, producing grand pseudobulbs, rich dark foliage, and handsome arched spikes of flowers. The most noteworthy plants are those of *Odontoglossum Alexandræ*. There are hundreds of them in 6, 7, and 8-inch pots, which will produce a harvest of flowers of the greatest value. They are plants which anyone may be justly proud of owning. Other *Odontoglossums* grown here in large numbers are *O. cirrhosum*, *O. Pescatorei*, *O. triumphans*, *O. Andersonianum*, and *O. gloriosum*. The plants are potted in a compost of sphagnum, the fibre of peat from which the loose soil has been knocked out, and charcoal. The pots are filled three parts full with drainage, and the compost is packed high above the rims. Fire heat is only employed in severe weather, and to keep the temperature from falling much below 50°. Thus easily and excellently are grown some of the most beautiful and useful of Orchids—plants that may be successfully grown behind the north walls of any private garden where glass shelter, slight heat, and cultural skill are provided. Another low span-roofed house 100 feet in length has on the bed on one side of the central path two thousand plants of the rich and chaste *Lælia anceps*, the other side being occupied with *Gardenias* planted out. Thousands of flowers of great value are provided in this structure. A similar pit is closely packed with small Palms, Begonias, and Harrison's Giant Musk. The last-mentioned plant is in great demand for decorative purposes, and is being increased very largely. Another house of the same dimensions is filled with *Eucharises*, *Spireas*, small *Azaleas*, *Pancratiums fragrans* and *speciosum*, and *Stephanotis* on the roof. The *Pancratiums* are found very useful for producing pure white flowers which are always in demand.

A very large and lofty structure is occupied with Oleanders, *Cytisuses*, *Cordylines*, *Camellias*, and other plants of considerable dimensions, the south side of the roof being covered with Tea and Noisette Roses, and the shelves filled with scented Geraniums, Lilies, &c. A similar house represents a forest of *Camellias*; another house of the same size being chiefly occupied with *Azaleas*, containing also *Kalosanthes* and *Callas*. A structure 160 feet long is crowded with *Roses*, *Pelargoniums*, and other plants for affording cut flowers, and another is filled with Palms. Two brick pits of the same length contain five thousand pots of *Lycopodium denticulatum*. This *Lycopodium* cannot be grown fast enough. *Isolepis gracilis* is also in constant demand. Five thousand pots of Lilies are forced, and apparently a greater number of *Spireas* (*Hoteias*). *Panicum variegatum* is also largely grown, as also are *Liliums*. The *Liliums longiflorum* and *auratum* are grown and flowered in 5-inch pots. One bulb is placed in each pot, which is only half filled with soil, and when growth commences the remaining space is filled up with rich manure. This and copious supplies of water enable plants with healthy foliage and fine flowers being produced in such small pots. The pots are plunged in cocoa-nut fibre refuse in beds on the south side of the houses, and the plants are left to grow without any further protection. Many hundreds of the former Lily are now about 6 inches high and have received no injury by frost. On the north sides of the houses bulbs are plunged, such as *Narcissuses*, *Tulips*, and *Hyacinths*. Many of these are grown for affording cut flowers, the bulbs being packed closely together in boxes only about 4 inches deep, and it is surprising to see what fine flowers are produced on this crowding system. Thousands of bulbs are so grown and flowered with little or no protection.

Such is the character of this plant and flower manufactory, from which vanloads of plants are constantly going out and coming in: going out fresh and bright, coming home seedy

or in tatters. Such as are recoverable have a course of hospital treatment and do duty again when in presentable condition; the incurables, and these are many, being thrown away. Notes on the Anerley Nursery are postponed.—VISITOR.

EARLY OPENING OF KEW GARDENS.

JUDGING from the communications from gardeners which have appeared in the gardening papers, it may be fairly taken for granted that the generality of horticulturists throughout the country are satisfied with the hour at which Kew Gardens have hitherto been opened to the public daily. I for one—and I speak both as a gardener and an old Kew *employee* knowing something of the arrangements there—think that the time of opening and other conditions of admitting the public to the gardens are perfectly satisfactory; and I fully believe this is the opinion of the majority of the public, or why should the agitation to open the garden earlier be chiefly confined to a few eating-house keepers about Kew? As a rule the causes for opening the gardens earlier held out by the few writers who have taken the matter up have no real foundation.

First, "The British public" are said to suffer greatly through the garden not being open till one o'clock. It appeared strange to me, and I have no doubt it would to others, that most of the original movers for early opening belong to Kew or its immediate vicinity. No doubt it must be highly gratifying to these gentlemen to consider themselves representing the "public," but it is to be hoped the authorities will see it proper to have a more "national" opinion on the matter before they make any alteration in the opening of Kew. That it is for local advantage from beginning to end must be apparent to every reasonable thinking person, and I was heartily glad to see that you did not hesitate to point the matter out in its true light.

At the "public" meeting held at Kew on August 21st, 1877, when it was resolved to procure the opening of Kew Gardens at ten o'clock in the morning, there was another resolution passed which fully verifies the self-interested character of the first resolution. To make matters plain. Going from Kew to Richmond by the public road the gardens are on one side of this road, and villas have been erected on the other side. No doubt whatever this has been done with the object of securing a view into the gardens, which, to anyone who knows how much a good view from a house near a town is valued, simply means an increase of rent. However, these enterprising builders have been disappointed in their "views," as the Kew Garden authorities found it necessary to raise the previously existing wall between the road and the garden; and however much this wall may shelter the tender, rare, and beautiful trees and shrubs with which the garden abounds it matters not, but the wall is objectionable to the "public," and the petition prays that it be removed.

There is another advantage which the people of Kew would derive from the gardens being opened in the forenoon that would have more influence in creating a public demonstration there than any of the reasons you pointed out. Nearly every other house in Kew is an eating house, and the increase of trade which the keepers of these would expect through people visiting Kew before they had lunched or dined fully accounts to me for the enthusiastic manner in which the resolutions were carried at the "public meeting."

Respecting horticulturists and those considering themselves as such, who are clamouring for the early opening of Kew, as might have been expected, Mr. T. Baines, Southgate, is conspicuous. Mr. Baines has my respect as a plant-grower, but I do not admire his opinions on Kew. Mr. Baines is very much shocked at your "insinuations" that those residing in the immediate neighbourhood want the garden open to satisfy their own requirements. Mr. Baines says, "There is unlimited space in the neighbourhood accessible—Richmond Park in particular—where those who only want to lounge about can do so." I am afraid Mr. Baines would not enjoy a lounge in Richmond Park very often if he lived in Kew, because the one is nearly three miles from the other, and walking this distance to and fro is hardly the thing "loungers" appreciate. Mr. Baines' ideas of garden work are also at fault when he asserts that all work necessary to be done in the houses at Kew can be accomplished before breakfast time. Watering is not the only operation that requires doing. Nearly all the plants at Kew are potted in the houses in which they are arranged; indeed, many of them are so large that they could not be removed to another place. But, briefly, it is not correct that

country gardeners, botanists, and such-like are not able to gain admittance, or have a difficulty in gaining an entrance, to Kew Gardens before the gates were opened to the general public at one o'clock. Gardeners, no matter who they are or from whence they come, are as freely admitted to Kew any hour of the day as they are to any nursery in London, and no one need be afraid to ask admittance, because it is always considered more a right than a favour to grant it. The whole amounts to this: Botanists and gardeners can gain admittance to the gardens at any hour of the day simply by stating that they are such, and it is perfectly absurd to pretend that the garden should be opened earlier on their account; but that this place of instruction should be open all hours of the day for the recreation of the masses is what I am sure every right-thinking intelligent gardener and botanist will do their utmost to prevent.—A KITCHEN GARDENER.

NOTES ON VILLA AND SUBURBAN GARDENING.

WHILE we write the ground is covered with snow, and the aspect is a wintry one indeed; but perhaps before these lines appear in print a change to warm and genial weather will have occurred. Anticipating the gentle showers and bright sunshine of April vegetation will soon be active, and the garden will again become an object of interest to the many who find recreation and delight in tending it. As soon as the change to pleasant spring-like weather is manifest the sowing of seeds of hardy and half-hardy annuals must be attended to for raising plants to flower throughout the summer. Perhaps there is no more simple and better way than to sow the seeds thinly where the plants are to remain to bloom, but in a few cases with the more tender plants—such as Ten-week Stocks, French and German Asters, double and single Zinnias, Phlox Drummondii, Petunias, &c.—it would be better to sow on an open warm border, sheltering the seed with handlights or spare garden frame lights whilst the seeds are germinating. Under such protection the young seedlings will flourish and make very sturdy plants for removing to their permanent quarters. Another way is to sow in boxes and place under the protection of a garden frame. Both plans point to the same object. We consider either of these modes better than sowing the seeds, as is too often done, in a very high temperature, in which the seedlings become drawn and weakly and the roots matted together, so that when the plants are planted in their blooming stations they are too weak to recover, and much of their after beauty is sacrificed.

Of the hardy annuals perhaps Mignonette claims the foremost rank, and should be sown in quantities in lines or in circles dotted here and there, making the prominent sowings near to the principal windows of a residence. Cover the seed very slightly with fine soil. There are many new and improved varieties now to be had quite as sweet-scented as the old common variety. Amongst them is Miles' Spiral Mignonette; its sturdy branching habit and powerful fragrance will render it a great favourite when better known. Many of the Everlastings are worthy of more general cultivation, such as Helichrysums and Xeranthemums in variety. They continue in bloom when well grown from the middle of summer until killed by frost, and are indispensable as a winter flower when wired and preserved for that purpose. Many of the Everlastings are also dyed, and are to be purchased in Covent Garden, where they are tastefully made into bouquets and emblematical devices. Rodanthe Manglesii and R. maculata and maculata alba are charming varieties of fine dwarf habit. The African and French Marigolds are very effective, and Tagetes signata pumila is fine for front lines, and has the advantage of flowering late in the summer, at which time its small yellow flowers are very attractive. The Godetias are brilliant and profuse-blooming annuals, and should be found in almost every garden, especially Godetia Lady Albemarle. All the Nemophilas are worthy of cultivation; their small bright flowers render them great favourites, and they are not very particular with regard to soil, and can be employed as bedding plants, for edgings, and on rockwork. Nemophila discoidalis, N. insignis grandiflora, and N. maculata are fine varieties. Dianthus Heddevigi and its many varieties must be included, together with the Larkspurs. Collinsias of all kinds are very beautiful and will add to variety, as also will Virginian Stocks, Limnanthes Douglasii, Clarkias, Eckscholtzias, Love-lies-bleeding, Candytuft, Nasturtiums, and Lupins. For screening-out unsightly objects the tall-growing Nasturtium, Tropaeolum canariense, and Sweet Peas are very suitable. Sunflowers are also welcomed by many, both the double and single varieties; they are well adapted for shrubberies, and in the autumn months are very conspicuous. We have observed, however, that rabbits are very partial to them, and therefore if those animals abound it would be useless attempting to grow Sunflowers. Ornamental Grasses are also very useful, their graceful forms and refreshing colours give a relief to the other occupants of a garden. The Stipa pennata or Feather Grass, Agrostis pulchella, the various Brizas or Quaking Grasses, and Piptatherum Thomasii can be all recommended.

Tender Annuals.—Where a hotbed is at work, or a house with artificial heat can be had, a sowing of Balsams, Cockscombs, and Globe Amaranthuses should be made early in the month, sowing the seed in shallow seed-pans, and subsequently pricking the seedlings off into small pots as soon as large enough to be handled, keeping them near the glass; in fact, it is a rule with all seedlings that ought never to be lost sight of, that the nearer the plants are to the glass the better and more sturdy they become. Chinese Primulas should now be sown, covering the seed very slightly; and where Cannas, Castor-oil Plants, and such-like sub-tropical plants are required, seed of them must be sown and the plants be brought forward in a light structure having a genial temperature, eventually hardening-off the plants for outdoor decoration. Variegated Maize, which contrasts effectively with dark-foliaged plants of stately growth, may be prepared in the same manner. Sow the seeds of all kinds of plants thinly, and promote a steady growth of the seedlings by affording them all the light and air possible, and by raising them in moderately, not violently, heated structures.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow Celery for the latest crop; the seed may be sown in a sheltered situation outdoors in rich moderately light soil, or in pans, placing them in a cold frame. Turnip-rooted Celery or Celeriac should now be sown. Its roots are valuable for soups. It requires to be planted on the level or in very slight trenches. Carrots for the main crop should now be sown. James's Intermediate Scarlet and Red Surrey are fine and good keepers. If Beet is required early a moderate sowing of Dewar's Dwarf Red may now be made in rows a foot apart, covering the seed an inch deep. The main crop of Beet, Salsafy, and Scorzonera should have a space of 15 inches distance between the rows, but we do not advise these crops being sown for another fortnight, as when sown early the plants are liable to run to seed. The ground, however, should have a dressing of quicklime, pointing it in with a fork with a view to the destruction of slugs. Sow on a sheltered bordered Sweet Basil, Sweet Marjoram, and Summer Savory. We sow in rows 9 inches apart. In cold localities defer the sowing for another fortnight. Thyme and Sage we sow about this time in rows 1 foot apart. Plantations of culinary herbs as are in request should now be made, such as are increased by division, allowing a distance of from a foot to 18 inches between the rows, and from plant to plant according to the requirements of each. Change of soil is as beneficial to these as to any other description of plant. A moderately warm or sheltered situation should be chosen. Our herbs are grown on an east border. Chervil should now be sown out of doors for a succession to that having stood the winter. The planting of second early Potatoes should now be completed, and the planting of late kinds proceeded with. The distance between the rows for ground in good heart, as most garden soils are, should not be less than 8 feet with from 15 to 18 inches between the sets for strong-growing sorts. Except in special cases late Potatoes should not be grown in gardens, they being much more profitably cultivated under field treatment.

HARDY FRUIT GARDEN.

Grafting should now be completed as soon as possible. This is an operation too much neglected in gardens. It is the readiest means of bringing barren trees into speedy bearing, as well as a desirable mode of introducing new varieties and such approved sorts as are found to do well in the locality. Instead of grubbing-up large trees of inferior varieties, trees that are barren yet healthy, head-back and graft them. Grafting is a very simple operation, and may be performed by any intelligent workman. Take a piece of firm ripe wood, and cut it slantingly from a point about 8 inches from its base on one side, making its slope quite through to the bark on the opposite side of the scion at its base. A slit about 3 inches long should be made in the bark of the stock through to the wood; a piece of wedge-like hard wood should be introduced into the cut between the bark and wood and pressed downwards about 2 inches, and this being withdrawn the graft is thrust-in in its place to the extent of the length of the slanting cut. Two or more grafts may be introduced into an arm, but they should not be so near each other as to separate the bark from the wood between the grafts. The grafts should have two buds clear of the clay. Secure the grafts with a ligature of matting, and cover the whole cuts and crown of the stock with a pigment formed of clay and cow dung, making it quite close about the crown and smooth so as to exclude air. A covering of moss tied over it and sprinkled occasionally will prevent cracking, to which the clay is liable if dry weather ensue. Scarcely a graft will fail provided they have been cut previous to the swelling of the buds and kept in soil so as to retard their growth until the sap is well up in the stock. The protection of fruit blossoms must be carefully attended to whenever the nights are frosty or likely to be so. Those having projecting coping will have found great advantage from it, but for sheltering from such severe driving snow-storms as we experienced some additional screens are necessary.

Glass copings are the best, and when supplemented with canvas in front of the trees the season must be uncommonly severe if the safety of the blossom and fruit are not insured. Recently planted trees should now be cut back to cause them to push shoots at the required distances apart for furnishing the wall or space.

FRUIT HOUSES.

Vines.—Those in the house started early in December are taking the last swell, and, especially if growing in inside borders, should be assisted by a good watering to the border with liquid manure at a temperature of 90°. Maintain atmospheric moisture by damping every available surface of the house three times a day. Do not syringe the Vines, but place liquid manure in the evaporation troughs. Admit air moderately but early, letting the temperature rise steadily to 85° with sun, closing the house at 80°; keep the heat at 70° to 75° by day by artificial means, and 70° to 65° at night. Black Hamburgs started about New-year's day are thinned and swelling fast. Water the border copiously with tepid liquid manure, not in dribblets, but giving sufficient to reach the drainage. A suitable temperature is 65° at night, 5° less in cold mornings, 70° by day, admitting a little air at that, and then increasing to 80° or 85° with sun and increased ventilation, closing at 80°, damping the house well at that time, and keeping the evaporation troughs supplied with liquid manure. Muscats started early in the year have set well; they should not be thinned until the berries are swelling freely, whereas Hamburgs should be thinned immediately the berries are formed. When Muscats are coming into flower the night temperature is maintained at 75° to 70° with a moderate circulation of air, damping then taking the place of syringing. When in flower we gently tap the stem of each bunch with the finger to disperse the pollen, and in the case of shy setters we go over them with a rather large camel's-hair brush. If pollen be deficient hold a sheet of paper beneath those bunches that have plenty whilst the bunches are being tapped, and the brush may be filled with the pollen and applied to those that are deficient. Attend to disbudding, tying, and stopping in the succession houses, thinning the bunches, removing all duplicates and imperfectly formed bunches, having the eye fixed more on quality and finish than a great crop of fruit, which is seldom satisfactory in the end. Late Vines recently started will in dull weather need artificial heat to keep them advancing, 65° by day by artificial means, 55° at night after the eyes break, increasing to 60° by the time they are in leaf and the fruit showing, 70° to 75° by day, admitting a little air at 70°, closing at 75°, damping the house at the same time and syringing overhead morning and afternoon. Any canes or rods not breaking regularly depress to the horizontal, or their ends below that until the eyes have started, then tie the rods to the trellis. Fermenting materials will have been removed from vineries that were started early, the Grapes of which will be colouring. A thorough soaking of liquid manure applied to the roots, mulching the soil with short manure, preferably recent horse droppings, which evolve ammonia, and checks red spider and also prevents evaporation from the border. Fermenting material on the outside borders of those started early must not be removed until the fruit is thoroughly ripened. Vines in pots swelling-off the fruit feed liberally with liquid manure.

Peaches and Nectarines.—We do not, as a rule, syringe the trees twice a day after the fruit is set and swelling, having proved that such practice is not a preventive of red spider; yet we syringe the foliage forcibly occasionally to keep it in check. Deficiency of moisture at the roots with a dry atmosphere promotes red spider, but this season we have not had the faintest trace of the enemy, having in addition to the usual top-dressing of manure and turfy loam applied bone dust and chemical manure (Amies'), washing the fertilisers in thoroughly. The evaporation troughs are kept full, and the house is damped three times a day. In the earliest house the stoning process will soon be over, but we make sure that it is complete by trial with a knife of the backwardest fruit before raising the temperature; 70° at night, 75° by day from fire heat, advancing to 85° or 90° from sun heat are suitable after stoning. Give a thorough watering to the border, the water being a few degrees higher in temperature than the mean of the house, and mulch the inside borders with short manure. Syringe twice a day, and damp at noon, and again at closing time in bright weather. Some varieties of Peach are subject to mildew, which yields to flowers of sulphur. Aphis upon its first appearance must be met promptly by fumigation; but be very careful, as the foliage of the Peach is tender. Keep the shoots well tied-in as they advance, and be careful not to overcrowd them. The foliage requires air and light for the maturation of the buds at its base, and the fruit requires sun for colouring perfectly. Attend to disbudding and thinning the fruit in the succession houses. Our latest forced house has set its fruit very thickly, as have all those preceding it, and requires frequent looking over for the reduction of their number, for thinning, like disbudding, requires to be done gradually, removing a few shoots at a time and a few of the smallest fruit daily. The trees in cool houses, which correspond to orchard houses, are in fine bloom; ventilate very freely, and go over the blossom with the brush on fine days, and see that the borders do not want for

moisture. Avoid a close confined moist atmosphere, especially in the case of unheated houses, for the blossoms are acted on by cold in proportion to the moisture, a low night temperature doing no harm provided the house be dry, but the means of excluding frost should not be wanting. In cold districts fire heat may in a dull period be necessary to secure a good set of fruit. Turn the heat on in the morning, admit air at 50° in addition to the little left on all night, which should be the maximum by artificial means. Shut off the heat at closing time, and the heat given off by the heated surface will be sufficient to exclude frost for the night.

Melons.—Give the plants a good watering when the fruit is set and of the size of a walnut, and earth-up the plants if not already done, ramming the soil firmly. Those plants already earthed and swelling off their crop may have an application of liquid manure, but it must be weak and be kept from the neck or collar of the plants, or it may induce canker, which, however, may be overcome by placing earth all around the stem after rubbing the cankered part dry with the lime. Remove all flowers, male and female, from plants the fruit of which is swelling freely, attending to stopping, thinning, and tying the shoots, which must not be allowed to crowd the principal foliage. Admit air early, then allow the temperature to rise gradually to 90° with sun, 75° to 70° by day from fire heat, 70° to 65° at night, bottom heat 85°. Syringe twice a day in bright weather, damping only in dull weather. Train the growths of successional plants. If the laterals are crowded remove every other when quite young as soon as visible, adding more soil to the sides of the ridges or hillocks as the roots protrude through the surface, stopping the shoots one joint beyond the fruit, or rather blossom, which should be impregnated in bright weather. A sowing should now be made for affording plants for frames which have been employed for early Potatoes, &c.

Cucumbers.—Keep an eye to red spider; syringing twice a day will keep it at bay provided every portion of the leaves is thoroughly wetted. Remove all damaged or old leaves, stop the shoots one joint beyond the fruit, thin out where likely to be too crowded, and avoid overcropping by early attention to the removal of superfluous fruit. Keep the evaporation troughs filled with liquid manure, admitting air early, increasing it with the increase of solar heat, avoiding cold draughts. Liquid manure will be required by plants in bearing, adding more soil to the ridges of advancing plants. Attend to the lining of the beds of frame plants, covering the glass at night with mats, &c. Day temperature 75° up to 90° with sun, night 70°; bottom heat 80° in frames, 85° in houses.

PLANT HOUSES.

Stove.—*Pancretrium caribæum*, fragrans, and ovatum have elegant white sweet-scented flowers, and the plants are of easy culture. They should be in every collection. They do well in rather strong turfy loam, and require abundance of water when growing. In potting these plants, also *Eucharis*, the bulbs should be entirely buried in the soil and a good space be left for watering. Old plants of winter-flowering *Begonias* should be renewed annually. Cuttings should now be inserted; they strike readily in gentle heat. Select cuttings of the strong growths and insert them singly in small pots. When well rooted transfer to 5-inch, and from those to 7, 8, or 9-inch pots, according as the plants are wanted medium-sized or large. To have them flower well they should have a light airy situation and be kept moderately moist. *B. fuchsoides*, *hybrida multiflora*, *insignis*, *Ingrami*, *semperflorens*, *Saundersi*, and *manicata* are good. *Plumbago coccinea superba* has fine scarlet flowers; cuttings of 4 to 6 inches in length, taken off with a heel, potted singly in loam and leaf soil, strike in moist gentle heat. It, as also *P. rosea*, are spoiled by growing in too strong heat. They should have a light airy position after being well rooted in an intermediate house, keeping moist. *Centradenia rosea* and *C. floribunda* cuttings struck now in sandy soil and grown on through the summer make fine winter-flowering plants, flowering from nearly every leaf. Early-flowered plants of *Franciscia* will have shoots available for cuttings of 4 to 6 inches in length, which with a heel root in a brisk heat in sand; they should when rooted be potted off in loam with a little leaf soil and be grown on through the summer. *F. calycina major* and *F. confertiflora* are the best. *Luculia gratissima* cuttings struck now and grown through the summer will flower in autumn, and from their moderate size are very serviceable. Cuttings should also be inserted of *Thyracanthus rutilans*, *Eranthemum pulchellum*, *Centropogon Lucyanus*, *Conoclinium ianthinum*, all of which are worth growing in quantity. *Æschynanthus splendidus*, *Lobbianum*, and *grandiflorus* are fine basket plants or for pots. A dozen cuttings placed around a 6-inch pot now in sandy loam and peat strike readily in gentle heat; when well rooted transfer them to the baskets, or shift into 8 or 9-inch pots. *Poinsettias* should after they have rested a time have water and be placed in a growing temperature, shortening back to about 6 inches from the soil those intended to be grown on, and those for affording cuttings shortened to firm wood. When they have made a little growth reduce the ball, return to the same size of pot, employing good loam. They cannot have too light a position, but too much heat draws them up weak. A temperature of 60° at night is sufficient for them. Look well after mealy bug and other insect pests, syringing in the

morning and afternoon, keeping the evaporation troughs filled with water and damping the house at noon. Avoid overwatering, but as the heat is greater more liberal supplies of water will be required, yet the soil is often made sodden by needless watering, which is worse than moderate dryness. Temperature 70° to 65° at night, 75° by day from fire heat, at which admit a little air, increasing it with the temperature to 85° from sun heat, closing at 80°. Have shading in readiness, but use it only in bright weather.

TRADE CATALOGUE RECEIVED.

William Paul & Son, Waltham Cross, Herts.—*Spring Catalogue of New Roses, Geraniums, Phloxes, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (Graw).—The book you mention is very good, and so is Sinclair's "Hortus Gramineus Woburnensis."

HORTICULTURAL (ROYAL) SOCIETY'S SCHEDULE (L. G.).—Write to the Secretary at South Kensington.

GARDENERS' PROVIDENT SOCIETY (W. T.).—The address of the Secretary is Mr. J. F. McElroy, Moray Lodge, Campden Hill, Kensington, London.

OUT-GOING TENANT (R. P. P.).—Legally you can neither remove the tree nor the edging tiles you put in at your own expense. Why not agree with the landlord first?

RIBBON BORDER ARRANGEMENTS (A Constant Reader).—In the first border discard the yellow *Calceolaria*, and repeat the *Centaurea* in its place. You will then have pale yellow, blue, grey, crimson, grey, scarlet; and your very capital mixture of Dahlias, Lilies, Gladioluses, Phloxes, and Delphiniums, mingled with shrubs behind. In the second border retain the yellow *Calceolaria*, and substitute Purple King *Verbena* for the scarlet *Geranium*.

ARRANGEMENT OF FLOWER GARDEN (W. T. C.).—The proposed mode of planting the beds is very good. This applies to both of the plans sent to us. We do not see how the plants named could be arranged to produce a better effect; the bright colours are well balanced and associated with neutral tints, which will produce a quiet yet cheerful display. We should adopt the plan for which the raising of plants would be the most convenient.

FLOWER BED ARRANGEMENTS (A. Y. M. Bott).—Diamonds and half diamonds make a pretty design for a border. Mark the outlines with a compact-growing plant with variegated foliage, plant each diamond with one distinct colour, and let them alternate harmoniously something in this way: Pink, grey, or white; purple, crimson, yellow; and in the half diamonds have such plants as Golden *Pyrethrum*, *Lobelia*, *Alternanthera*, and *Cerastium*. In the group of beds on the lawn plant the central bed entirely with *Zinnias*, and have your *Geraniums* in the outer beds, a distinct sort in each bed.

CULTURE OF ROSES IN POTS (Idem).—Keep your Roses under glass till the weather becomes warm, say the third week in May, then plunge them to the rim of the pots in a bed of coal ashes in an open sunny position. Keep down weeds, and give occasional doses of liquid manure to assist the growth, the progress of which will be your best guide as to the frequent use of stimulants or otherwise. Early in October thin-out the growth and prune to about four eyes, turn each plant carefully out of the pot, examine and put right any defect in the drainage, repot in the same pots, or use a size larger for any very strong plants, but do not shake much of the soil off when the roots appear healthy, strong, and abundant. When, however, it is at all sour, and the roots are not in good condition, shake off the whole of the soil, and repot in a mixture of turfy loam and old decayed dung. They may then be placed in a pit or cool frame, and taken into the greenhouse at the end of the year. Your object in growing Roses in pots is to obtain bloom before it can be had in the open air, and it is better, therefore, to devote your plants specially to this purpose, and not attempt the production of a second crop of flowers in the same season.

ROSE SHOOTS DESTROYED BY FROST (E. C. Burton).—Wait till genial weather induces fresh growth, which will spring from the base of the frozen shoots, and then cut away any dead shoots down to the new growth. The Wallflower is Golden Queen.

SELLING ROSES (P. H. G.).—We know of no purchasers except the dealers in Covent Garden Market, and among these you must inquire.

DUCHESS OF EDINBURGH TEA ROSE (A Lover of Roses).—This Rose was sent out by Messrs. Veitch & Son in 1874, and received a first-class certificate from the Royal Horticultural Society on the 13th of May of that year. It is a very pretty free-blooming variety with deep rosy crimson flowers of good shape, and excellent for buttonholes or bouquets. It resembles a China Rose as much as a Tea. It is highly suitable for early forcing, and would doubtless prove a first-class Rose for beds. A Hybrid Perpetual Rose of the same name was sent out in the same year by Mr. Bennett of Stapleford.

EVERGREEN CREEPER FOR A VERANDAH (J. T.).—*Berberidopsis corallina* is a fast-growing climber, with persistent, stout, deep-green foliage and crimson flowers. If the situation is bleak and cold it would be better to choose the *Pyracantha* or *Escallonia macrantha*, which are quite hardy in cold exposed positions and very ornamental, but not quite so rapid in growth as the *Berberidopsis*. You neither state your locality nor the aspect of your verandah, which renders it difficult to answer your question.

VIOLETS (A Country Vicar).—We believe the wild white Violet to be much more prolific than the blue one, at any rate that happens to be the case in

the neighbourhood in which we reside. Flowers of an intermediate shade doubtless arise from the distribution of the pollen by insects.

AUCUBA POLLEN.—A Ghent nurseryman asks where he can procure it. We shall be obliged by an answer.

BURNHAM BEECHES (J. B.).—Tradition says that the Burnham Beeches were pollarded more than eight hundred years ago—namely, in the reign of Canute. We have no notes of historical events connected with them.

REMOVAL OF FRUIT TREES AT MIDSUMMER (W. B. T.).—Turn the fact of paraffin oil being sold near you to account by purchasing some of the empty casks; they are inexpensive. Cut them asunder, making a couple of tubs of each cask. Bore some holes with an auger in the bottom of each, lift your trees immediately, and plant one in each tub in some of your best garden soil; secure them with wire to the edges of the tubs, attend well to watering, and you may take them from one end of England to the other at midsummer. Try and turn them out of the tubs as early as possible in autumn, or, better still, if after the removal you can continue to break away the sides and bottoms of the tubs at midsummer without disturbance of the balls of soil, you might secure some growth this year and a fair crop of fruit in the next. The Roses might be treated in a similar manner, placing three or four in each tub. The Geraniums may remain in the pots, and will only require due attention to the necessary watering.

VINE AIR ROOTS (H.).—They are caused by vigorous root-action and the extreme moisture of the heated air.

PLANTING VINES (J. B.).—The Vines should not be planted nearer to each other than 3 feet 6 inches. No Vine is so certain and so serviceable as the Black Hamburg. If you want an early white variety plant Buckland Sweetwater. As a later amber-coloured Grape none equals Muscat of Alexandria, and for this you would have sufficient heat in your No. 2 house. If you want variety you might also plant in the same house Madresfield Court, Black Alicante, and Lady Downe's Seedling. Black Alicante is large, late, and free; Lady Downe's later, smaller, and of better quality. You give us no data as to your particular requirements. If you simply want Grapes of the greatest usefulness and the best quality plant No. 1 house with Black Hamburgs, and No. 2 with Muscat of Alexandrias. The site for the Vine border must in the first place be well drained—there must be no stagnant water. If the position is low and wet make the border nearly or quite above the level of the ground. The best soil for Vines is the top spit or paring from a fertile pasture, mixing half a bushel of crushed bones to each cart-load of soil; but ordinary garden soil made fertile by the addition of bones and soot will grow good Grapes if the surface of the border is heavily mulched with manure. The border should not be less than 2 feet deep. We should make the soil good both inside and outside of the house, plant the Vines inside, and make openings in the wall for the roots to pass through into the outside border. You should procure the Vines at once before the buds swell. Keep them in the pots until they have made shoots an inch or two long, then shake all the soil from the roots and spread them straight and regularly in the soil, cover them 4 inches deep, and water with warm water, the work to be done expeditiously yet carefully.

CUCUMBERS FAILING (Y. J. M.).—We think your plants had neither sufficient support at the root nor air admitted soon enough in the morning. Even although you adopted the good plan of leaving a little air on all night by propping up the lights about half an inch, still in the bright sultry weather of summer additional ventilation is required long before 7.30 A.M. As soon as the sun has raised the temperature of the frame 5° additional ventilation is necessary. This may occur at 6 A.M. if the frames are exposed to the morning sun. Suppose the night temperature of the frame is 60°—i.e., that the thermometer denotes that figure before the sun reaches the frames in the morning, as soon as it rises to 65° more air should be given, increasing it at every 5° increase of temperature, and not permitting it to exceed 85°, the thermometer in the frame being effectually shaded from the sun's rays. As soon as the thermometer commences sinking in the afternoon reduce the air, keeping up the temperature to 80° as long as possible, closing the lights entirely when you are sure the heat will not exceed 85°. Water copiously at closing time. During sultry weather when the plants are in full bearing quite four gallons of water will be necessary for each light 6 feet by 3; but the quantity must be determined by the condition of the plants and the weather. If the foliage is light in colour during the fruiting period apply liquid manure twice a week. Sprinkle the foliage and every part of the frame well at closing time, and an hour or two afterwards prop-up the lights half an inch for the night. Plant on hillocks, and add fresh soil as the roots protrude through the surface, applying it 2 or 3 inches thick at a time, until the soil is level all over the frame. If you adopt this practice, and your soil and the variety are good and you do not allow the growth to be overcrowded, you will have plenty of Cucumbers in due time.

PEAS FOR AUGUST (Amateur).—Peas sown the first week in May would be ready for table by the end of July. To make sure of a supply of Fillbasket in the middle of August we should make two sowings, the first about the 8th of May, and the second about the 18th.

PRUNING ROSES (B. D.).—If your Roses have passed the late severe weather unharmed allow the shoots to remain, for on closer observation you will find the flower buds already forming. Marsechal Neil requires but very little pruning at any season.

NAME OF PLANT (Lady C.).—*Anacharis alsinastrium*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

FIELD CULTURE OF CARROTS.

THREE varieties of carrots are adapted for field culture, and produce excellent food for cattle, sheep, pigs, and horses. The white Belgian stands first in our estimation for use on the farm. The Red Intermediate and Long Altringham are, however, grown to some extent when there is a probability of the crop being required for sale in the towns as food for the people: upon some soils carrots produce profitable crops for that purpose.

the Intermediate being the best, and the roots are taken up from the ground at the least expense. We will first consider the cultivation of the white Belgian carrot for consumption on the home farm. Sand and sandy loam we have always found best for this crop; but we have seen fine and valuable produce on gravelly and strong soils where cultivated with care and judiciously treated during growth. Light chalk and very tenacious clays and marls are not suitable, and it is hopeless to attempt carrot culture on those soils. Carrots have not yet been grown so generally in the field as they deserve, and as we at one time thought they would be. They certainly require much hand labour at certain periods of their growth; it is, therefore, fair to infer that in some districts the difficulty of obtaining sufficient men or women to do the work has prevented the extension of their culture. We will now endeavour to show how much the labour attending their growth may be curtailed. It used to be the practice to sow the seed in the early part of March, but we prefer to delay the seed time until the end of April or early in May, at which time the young plants start fair with the weeds, and in consequence one hand-hoeing at least is saved. Ridge or baulk culture also saves much labour, as the land can be horse-hoed between the ridges before the young plants are strong enough to be hand-hoed; and upon shallow soils, when the land is formed into ridges at about 20 inches apart, it gives the plant a greater depth of soil to root in, and also facilitates the cleaning of the land at all stages of the growth of the crop. Another advantage in delaying the seed time as above stated is that it gives six weeks more time to prepare and clean the land, which is of great consequence in an adverse season, particularly on sandy soils, which are subject to the white-rooted couch grass.

In tilling the land for Carrots it is a question of soil, for where sandy it usually requires but little tillage; but the heavier soils will necessitate an autumn fallow, and then, after being exposed to the changes of weather during winter, we have obtained upon some parts of our land very good carrots; for although the roots have grown more out of ground, yet they have proved a heavy and valuable produce. We have always considered that the roots grown on strong heavy loams have a higher feeding value than the produce of the sandy and lighter soils. Carrots must be considered as a valuable alternation with other root crops, and in those cases where Swedish and common turnips have been cultivated for a series of years, both mangold and carrots offer an excellent change in root cultivation. Many years ago, after cultivating Swedish turnips without a change, we found under our system of very high manuring that the roots would not keep for feeding on the land after the month of November, and in consequence we resorted to the growth of carrots, which was a great success, and enabled us to make better sheep and cattle than we had ever turned out before. In consequence we made the carrot crop the principal substitute for other root crops, except mangold, for a number of years, and we have not hesitated when occasion required to grow this crop successively on the same land and with more advantage than with other root crops. The tillage for carrots should be the finest possible, extended to the greatest depth practicable, and the land made entirely free from grass and weeds. When the carrots have been sown after a fallow crop, such as rye, trifolium, or stubble turnips, we prefer one ploughing only, because there is but little time to do more tillage; and the loss of moisture in some seasons is a serious drawback; and where the land is made fine after a fallow crop we have grown good and weighty crops. When carrots are to follow a wheat or barley crop it is well to carry out a course of tillage after harvest by ploughing the land as deep as the furrow can be turned, the subsoil plough following, stirring the land to a good depth, then harrowing and rolling it until quite fine. If the season permit plough and subsoil as before, crossways, and allow it to remain in that state during the winter until the month of March, then harrow down fine and as level as possible, and as soon as the weeds make their appearance destroy them by the

scarifier and harrows a day or two before the time appointed for seeding. In case of the crop following that of wheat it often happens that the land is partially infested with couch grass and root weeds, which should be destroyed by the use of the scarifier, and removed or burnt previous to the commencement of the above-named course of tillage.

In all soils congenial to the growth of carrots, where a liberal course of cultivation has been pursued for some years previously, we do not find the carrot crop requires any manure, a large and heavy produce being almost certain; yet we have found it advantageous to drill with the seed about 2 cwt. of bone superphosphate per acre with a few ashes for the purpose of forwarding the young plants earlier to the hoe and in advance of the weeds. We cannot advise the use of farmyard dung for this crop, but in case of land being out of cultivation, or not well suited for the crop, we would apply some artificial manure. We think that Peruvian guano is best, and applied broadcast previous to the last ploughing, as we have found when harrowed-in on the surface it encourages the growth of weeds, and causes the carrot plant to throw out an unusual number of small surface roots, which are detrimental to its most profitable growth.

The seed should be quite new, and the quantity required is about 7 lbs. per acre, which should be hand-rubbed and entirely free from the burr, which is done with leather harvest gloves. It may then be drilled with great regularity; and we consider this is much to be preferred to the plan of mixing the seed with ashes. In some cases where mangold wurtzel seed is drilled on bank or ridges we have found it answer a good purpose to drill carrots on every other ridge, thus growing a double crop, and it is found that the mangolds are benefited by having more space; in fact, it is often the case that a full crop of mangolds is obtained with eight or ten tons of carrots per acre extra produce. Upon all well tilled soils adapted to carrot culture we have found the best mode is to drill upon the flat at 14 or 16 inches apart; for although the horse hoe cannot be so readily used at this distance, the hand hoe will be effectual, because the foliage soon meets across the space between the drills, and permanently checks the growth of weeds during the remainder of the season. The flat hoeing should be commenced between the rows as soon as the lines can be distinctly seen, and after the plants have attained the height of 5 or 6 inches we use a 4-inch hand hoe, and cut them out into little bunches 4 inches apart. Women or boys follow and single out the bunches, leaving the strongest plants. Only one more hoeing will then be necessary if the season has been favourable. A few tall weeds may arise during the summer, which, with the plants that may have run up to seed, should be hand-pulled.

Our experience tells us that there is only one enemy to be feared in cultivating carrots, and by which we have sometimes lost our crop. It is a brown grub which eats off the root just under ground, and they attack the plant just after being set out by the hoe. To meet this contingency we have found it advantageous to defer thinning the plants as long as possible, say for a fortnight after they have been hoed across the drills; they then get strong enough to hand-pull, and large enough to pay for the labour. We have often pulled eight or nine tons per acre, and carried the produce away for feeding cattle, pigs, &c., without injury to the main crop. When the pulling of the plants takes place it opens and loosens the ground round the remaining plants, and they swell very large in consequence. We have often grown twenty-five tons of roots per acre after having pulled and used the thinnings.

The usual time of taking-up and storing the crop is during the months of October and early part of November; but in case of growing them to any considerable extent it will answer the purpose to commence somewhat earlier; for although the roots may be in a growing state, yet such is the value of the greens whilst in full growth, that a portion of the root might be sacrificed in order that a heavy crop of greens may be used for feeding at an earlier period. We have often secured eight tons of greens in this way for the daily feeding of cattle, both dairy cows and fattening bullocks at the stalls. Lifting the crop should be performed with a strong steel five-grained prong inserted at the side of the plant, and by pressing the prong obliquely with one hand, and pulling the greens of the plant perpendicularly with the other, the roots are lifted without breaking-off under ground, which, without due care, they are liable to do. Storing the roots must in a great measure depend upon the use to be made of them. When required for horses, cattle, pigs, &c., they may be well kept by placing in a continuous heap, about 4 feet wide at bottom, carried up to a point, and thatched with straw, fern, or seaweed, and having a light covering of earth; for although frost will not rot them like mangolds or potatoes, yet they lose a portion of their nutrition after being frozen. When required for sheep in open field feeding the best plan is to pit them upon the land by making small heaps, covering them with earth only. Hares and rabbits are so fond of this root that they will come for miles to eat them, and great depredation would be committed if not covered with earth.

We have found that carrots are cultivated at no more cost than Swedish turnips, and are certainly more valuable for feeding.

Our experience on this point is confirmed by the analysis as given by Dr. Voelcker. In conclusion it cannot be doubted that after paying for deep tillage and clean cultivation this crop is entitled to be considered superior to most other root crops. The circumstance of being able to feed or fatten all the live stock of the farm, including poultry, with a crop which requires only a limited outlay for manure, is at once peculiar and decisive, and is calculated to excite some degree of wonder that its cultivation has not been more extended.

WORK ON THE HOME FARM.

The horses will be still engaged in tillage work connected with planting potatoes, sowing of oats, sowing of barley, and also of summer vetches. As soon as these matters are disposed of every opportunity should be taken to forward the land for the early root crops, such as carrots and mangold. This may be done when showers stop the seeding of Lent corn, for it often happens in showery weather that the ploughing of land for root crops may be done when other work connected with the seed time is at a standstill. Rolling of grass land is still the work for the period, and should not longer be delayed. This work also may be done after rain with advantage. It is also very desirable that manures required should now be purchased and placed in a manure house having a dry stone floor, so that the breaking and preparing of guano may be effected, and the different artificial manures may be kept dry, and where they may be mixed and bagged ready for use when required. It is important that in case manure is put away for use and required to be sown by hand broadcast that it should be understood as so many bushels per acre, as the seedsmen know little about cwt.; but in case the manures mixed with ashes, &c., are reduced to bushels they immediately understand how to sow the correct quantity, because with all men accustomed to sow corn as so many bushels they can readily measure the quantity by their hand. The odd horse, certainly one of the most useful on the farm if judiciously employed, will now as ever be required to carry out work connected with the decent appearance of the farmstead, rickyard, &c. Upon properties where there are often woodlands, plantations, beather, and gorse lands, as straw is now so dear and so requisite on the home farm its substitutes should be carefully collected and preserved, such as ferns and leaves of trees of last year's growth lying about in abundance, and only requiring women or boys to rake together and be carried to the farm and used instead of straw in the cow stalls and pigsties to the advantage of the manure supply. At this time of year the hand labour will be required in collecting couch and weeds on the fallows where tillage is going on. Women also will now be required to pick up stones on the pastures and fields in clover, &c., and also in cutting the earliest docks and other deep-rooted weeds as fast as they appear.

The lambing season is in the southern counties nearly completed, but in the midland and northern counties is now going on, and in either case the shepherds have constant and unremitting employment, such as feeding the ewes and lambs with great regularity. Especial care is requisite when changing the stock from one field to another, particularly if the root food differs; we therefore always in removing stock take care in the case of changing from turnips to swedes, or from swedes to mangold, to have some of each kind of food exchanged, so that some of the food be taken from the field where they are leaving and carried to that where they are to enter upon, and the reverse. Within the past few years the labour question has changed so much that we now have as much work on the farm as possible accomplished by piecework. As the root crop is abundant we are now obliged to cut up the swedes and plough them in or lose the season for sowing the barley. We have seen the Lent corn better sometimes after ploughing-in the roots than after feeding off by sheep.

In connection with home farm management we have again had our attention called to the danger of allowing yew trees to be growing in pasture and park lands by the loss of a fine and valuable herd of Highland cattle belonging to the Earl of Lovelace, in consequence of having eaten the cuttings of yew trees. We also know of other losses in our own neighbourhood lately from the same cause. We therefore recommend that all yew trees not required for ornament should be immediately grubbed up in lands frequented by cattle. It is no use to cut them down level with the ground, for the young shoots which spring up are the most dangerous of any. Where, however, the trees are required for appearance in parks they should be well fenced with strong iron cattle hurdles at a distance to entirely prevent the cattle from reaching the branches of the trees; this will not only prevent injury to cattle, but it will not prejudice these ornamental objects, for at a distance the iron hurdles would be comparatively invisible.

MANAGEMENT OF SPRING CHICKENS.

WHILE we write the weather is about as unfavourable for early chickens as it can possibly be. A furious north-easter prevailed and a drifting snowstorm, while a thermometer not far from our own chicken houses has registered nightly about 7° frost for a

week past. We can only trust that ere these lines are in print a genial change may have taken place in the skies. A few weeks ago, when spring seemed to have come indeed, we gave a few hints derived from our own experience about precautions to be taken alike for breeding stock and for newly hatched chickens in this variable season: we proceed to fulfil our promise of supplementing them with some hints on the management of the young stock as they grow.

It is almost needless to say that in this inclement weather the coops should be well sheltered. We do not approve, save in the case of very delicate varieties, of chickens ever being boxed up in houses; but if possible the coops should be so placed that the inmates can run out and enjoy every transient gleam of sunshine, and at the same time be able to escape from the fury of the wind. We always prefer having chickens hatched in a cold fit of weather. They bear it excellently at first, and then when a genial change comes they fully enjoy it; if, on the other hand, they are hatched in an exceptionally warm time, and cold then succeeds while they are delicate with the rapid growth of first feathers, they suffer much from it; consequently when, as so often happens in this climate, winter comes after spring, those which have been hatched in the latter season require special care. Our own have this year been caught by the cold in their most delicate stage and are chiefly not of the most robust kinds, still we have not lost any. We will give our own system for what it is worth. The coops are placed in a row of sheds. These sheds are open towards the south-east and boarded on the other side; their high-pitched roof comes down on the open side to 4 feet from the ground. Each shed has a grass run in front of it 30 feet long and 7 broad, boarded all round 3 feet from the ground. Wet or dry the chickens can always run into these yards; there they get the maximum of sunshine and the minimum of wind, and thrive much better than if coddled up in close sheds. Of course in really fine weather they are let out beyond the yards on to grass or into shrubberies, but the shed yards enable them to have constant exercise with little exposure. Every poultry-keeper cannot have such an arrangement, but many substitutes for it are feasible, such as putting coops under wide eaves of a building or against a banked hedge, or making a temporary lean-to shed against a wall with posts and a sheet of zinc or felt.

Authorities differ as to whether chickens should be taken away from the hen before she would naturally leave them. We never take away a hen till she pecks her chickens. Oftentimes we have sacrificed a batch of eggs from a valuable bird because she returned to brood her chickens at night. When the time at last comes at which maternal affection ceases the question arises where and how are the chickens to sleep at night? This depends somewhat upon the kind kept. The Asiatic breeds, Cochins and Brahmas, do best on the ground altogether if only the coop is placed on really dusty dry soil, or if a house is given up to them with a similar flooring. Dorkings, too, up to ten or twelve weeks old even should live on the ground: where this is not dry it is a good plan to have a little platform of wooden lattice a few inches high, or even a truss of faggots to keep them out of the damp. The lighter varieties, as Bantams, Hamburgs, and Polands, do all the better for perching at once, or even while with the hen before she has left them. We formerly kept Dorkings, like Cochins or Brahmas, on the ground up to four or six months old, but are now convinced that this is not good for their legs and toes. We prefer their perching at ten weeks old or so, and that on perches which they can clasp well with their claws. It is the natural attitude for roosting, and we believe the best.

Then as to food, we continue the diet of boiled or scalded oatmeal made crumbly with other meal. The latter is varied and its quantity gradually increased till very little or no oatmeal proper is given, but ground oats—i.e., the whole oat ground to powder, and barley meal. Kitchen scraps are admirable for at least one meal. Whenever we have seen peculiarly forward chickens we have found that they had much of this fare. Great breeders seem much divided as to the utility of bone meal. Some of the most experienced have told us that they have found it utterly useless, others that they believe it to be invaluable for giving stamina. Our own opinion is that all depends upon the quality of it; we certainly once bought some which apparently caused the death of several young chickens from hardness of crop. We understand that the refuse dust from ivory-turning is sold for crushed bones, and this must certainly be pernicious; but if veritable fresh bones crushed can be obtained our idea is that, mixed in small quantities with the other meal, it is an admirable addition to the fare. At from ten to twelve weeks, according to the time of year, it is necessary to separate the sexes of the larger varieties in which size is a point. We prefer letting cockerels and pullets of the smaller kinds run together; the former mature more quickly, so get their masculine plumage earlier in perfection. It is often a question, where accommodation is small, how to manage this separation. We should advise two yards of moderate dimensions being made, both to open into a larger range, into which the cockerels and pullets may be alternately let out. They should not, however, be able to see each other, or they will fret and pine. In case it is absolutely necessary to shut up the birds of one sex

entirely in a small run we advise that the pullets be so treated. Cockerels require more exercise for the proper development of their limbs, and are apt if much confined to increase in flesh rather than in bone, and so become weakly and even deformed.—C.

PROFIT OF POULTRY KEEPING.

THE experiment began on March 1st, 1877, when I purchased ten hens and a cock of ordinary breed, but carefully chosen for points. By summer two of the hens had to be killed, and out of the chickens five died through accident, leaving the following balance at the end of the year:—

Dr.	£ s. d.	Cr.	£ s. d.
10 Hens and Cock	1 10 8	2 Hens killed	0 5 0
Fowl House	2 0 0	43 Chickens used	5 15 0
Coop, Wages, &c.	0 15 1	1223 Eggs	5 4 6
Food	7 7 2	8 Hens left	0 16 0
		40 Pullets	0 0 0
		Manure and Feathers	0 5 0
Balance	11 12 6		
	£17 5 6		£17 5 6

The first brood was 'spratched' on March 19th, the pullets out of which began laying at the end of and in August.

I began this year with four cockerels and forty-two hens, disposing of one cockerel and six pullets in the middle of February. The eggs laid in January were 465, in February 513, which facts I mention in reference to a paragraph in your issue of March 7th. My first two broods of fifteen and ten were hatched on Valentine's day, while out of sixty-six chickens five have died through accident, and five more broods are expected this week. Last year's pullets weigh up to 8 lbs., the two cockerels 9½ lbs. each. The birds have a first-rate run and all kitchen scraps; beyond, success has depended on care. By selection and crossing the trial is being made of getting hens to lay from 150 to 250 eggs each per annum, as Mr. Wright thinks they may be induced to do. The average weight of the eggs laid I find to be 2½ ozs.—GEORGE BOSTOCK, *Kirkby Wharfe Vicarage*.

THE RED-FACED SPANISH FOWL.

I HAVE been somewhat surprised that we have not had, that I remember, a fair description of the merits of the true red-faced Spanish fowl; probably it arises from the breed being greatly confined to the west of England, but I feel sure that, were their merits more known, they would soon spread.

I have tried most of the breeds for many years, but find none to equal them as hardy layers for profit. The white-faced must have sprung from this breed. They are so much more tender at moulting time, smaller, and so often when highly bred go blind, that I have given them up in favour of the above. The red-faced when true are such enormous layers, never wanting to sit, so hardy, large, and easily reared, that I wish the central poultry societies would give more attention to them as a class. There are three colours of them—white, black and blue, all of equal merit. The male birds should weigh 7 lbs. when nine months old.—A WESTERN SUBSCRIBER.

NOTES ON CANARY BREEDING.

IN reply to a correspondent who had benefited by former advice, and who sought information on the above subject, Mr. Barnesby writes:—It is satisfactory for me to know that your apparently dying Canary has, under the treatment recommended, been restored to health and song. In the way of making a start in bird-breeding I have always made choice of St. Patrick's day. Why I have chosen that particular day I cannot say more than I have thought St. Valentine's day (an old-fashioned day with many) too early to commence Canary breeding, owing to there being less certainty of success with the searching month of March before us.

Canaries at the age of two years are more matured for breeding (especially hens) than yearlings. The hens at the former age are better able to withstand our variable climate in the spring with less fear of their becoming egg-bound, which is a most distressing complaint. At the period of the hens depositing their eggs in their nests they should be freely supplied with fresh green food (dandelion and young lettuce, or salad for choice). If when placing the birds together you perceive that the cock hunts or drives the hen about the cage, do not set it down for a fact they will not pair. A little sparring and hunting about the cage mostly terminates in the warmest affection between the pair. Canaries vary much in temperament, and when two obstinate tempers meet there is often a considerable amount of jarring betwixt the two as to which shall "rule the roost." The cock bird mostly comes off victor, excepting as regards the particular duty appertaining to the nesting duties of the birds' household. Even in some instances the cocks are so dominating that the hens lead a not-over-pleasant life, but this is somewhat exceptional.

Your pair of Canaries, having been acclimatised to the temperature of the room, must by all means be allowed to remain therein, because if removed to the "colder room having a north aspect," they would, just at the time when all hope was centred upon them bringing forth their young broods, be found to be casting their feathers—a very common occurrence when birds are removed from a temperature of some 65° to another 10° colder. When a moult is thus brought about very little hopes remain for success during that particular season.

If you have not already a breeding cage possess yourself with one 24 inches or upwards in length and of moderate height, with hooks or nails in the cage to hang a couple of nest boxes on. Fix the cage in a snug corner of the room, and as the birds are well used to your family you need not fear that the domestic duties of your household will at all militate against them. Canaries readily habituate themselves to the various movements constantly occurring, and if any little household noises occur at times the birds seem to lend their aid in the way of accompaniment. At once place the pair of birds in the cage previously supplied with gravel, seed, and water, and in addition supply them with egg and bun crumbs, and, if after a few days you perceive the cock bird making advances to his mate in the way of chattering and offering to feed her, you may set that matter down as a "positive" that a mutual understanding exists between the two. Supply the birds with moss either placed inside the cage between the wires; or, if you prefer it, hang outside the wires a small net-full of moss and cow-hair, which may be purchased at a London bird-dealer's shop. My plan is to supply the birds with a moderate quantity of moss and fine hay mixed, and when you perceive that the hen has set herself in earnest to deposit the building material in one of the nest boxes, give her in addition a little cow-hair or deer's-hair for the final touch in completing her nest architecture. When the hen has made choice of the boxes remove the other box until the young are a fortnight old, when you may replace it upon the hook for the hen to build her next nest in. If you delay supplying a fresh nest box beyond the fortnight the young birds will soon leave the old nest, and will most likely have their feathers plucked by the hen to line the new nest. When the young have entirely left the old nest burn it and clean the box ready for use.

VARIETIES.

BIRMINGHAM CATTLE AND POULTRY SHOW.—The Committee meet on or about 15th inst. to revise the prize list for the present year, previous to which date Mr. Lythall, the Secretary, will feel obliged if anyone wishing to offer special prizes or to make any suggestions as to alterations will communicate with him.

—THE *American Poultry World* contains the following on rearing ducks:—Whether ducklings be brought out under ducks or hens, the young birds should be kept away from the water until they are three to five weeks old. This looks as if the advice were unnatural, but three-fourths of the young ducks that are lost in early infancy are killed by cramps and chills from allowing them to rush into cold water before the down upon their skin is thick enough to resist these ill effects. Ducks are aquatic, but are not marines! Most persons suppose that they belong to the water as fish do. The wild waterfowl have an oily coat that helps to preserve them, while domesticated ducks lose this under home cultivation.

—**CORN AVERAGES.**—The following is an official statement showing the quantities sold and average price of British corn, imperial measure, as received from the inspectors and officers of excise in the week ended March 30th, 1878:—Wheat, 32,503 qrs. 7 bush., 48s. 9d.; barley, 22,966 qrs. 2 bush., 41s. 5d.; oats, 4606 qrs. 6 bush., 23s. 11d. Comparative statement for the corresponding week in each of the years from 1874 to 1877:—

	Average			Average			Average	
	Qrs. Bus.	s. d.		Qrs. Bus.	s. d.		Qrs. Bus.	s. d.
1874 ..	36,701 5	60 3	..	15,553 6	48 9	..	2810 4	28 2
1875 ..	46,699 6	49 5	..	14,514 3	41 3	..	3272 4	30 3
1876 ..	41,246 1	44 4	..	29,917 2	33 7	..	2657 0	25 2
1877 ..	37,798 6	51 1	..	22,191 1	41 4	..	3142 2	24 6

—OWING to the bad state of the weather there was very little fodder offering at Whitechapel on Monday the 30th ult., and trade was dull. Prime clover, 100s. to 140s.; inferior ditto, 85s. to 95s.; prime meadow hay, 85s. to 100s.; inferior ditto, 70s. to 80s.; and straw, 44s. to 53s. per load.

—EXPERIMENTAL feeding trials, says the *American Cultivator*, have been made between Hereford steers and selected specimens of other pure breeds, which have ended in the uniform result that the former have yielded the best returns to the grazier for the food consumed. Careful breeders claim that the Herefords are the fastest feeders known, particularly on grass. Where a breed is wanted that will furnish good workers, hardiness and great aptitude to fatten, the Herefords display such qualifications to an eminent degree. They are very docile and hardy, being very easy keepers, and will no doubt stand a long severe winter and come out ahead of the Shorthorns in the spring on two-thirds the cost

of keeping. As a fact of great importance to graziers, it has been demonstrated in Australia that the Hereford breed surpasses all others in ability to endure periods of dearth and drought, while it is admitted this breed travels long distances with far less fatigue and loss of flesh than other breeds.

—M. REVEL, of Vic-sur Cère, the author of a prize essay on the milking of cows, states that owing to an unfortunate spirit of rivalry common among young milkers, they often make it a point of honour to try and get their pails filled in the quickest time possible; consequently they only draw from each cow as much of her milk as is given down rapidly and readily, and leave a considerable quantity behind; or, again, in the case of an easy-milking cow, they will drain her to the last drop, and leave nothing for the calf. In this way they may fill their pails rapidly, but the interests of the owner suffer for it ultimately; and he will do well to assure himself from time to time by personal trial that one cow is not left for another till she is fairly milked out.

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

No. 5.

BEFORE I proceed with my subject I must just notice the kindly remarks of your correspondent, "A RENFREWSHIRE BEE-KEEPER," relative to my qualified approval of the permitted swarming of each hive once a year in preference to a too strict adherence to the non-swarming system absolutely in every case. In cases like this there must needs be differences of opinion where the particular practice has differed on which our experience has been founded. I can only say that I wrote in good faith what my forty years' learning in the school of apiculture has taught me; but I have no manner of doubt that your correspondent describes a method of dealing with his hives which, in experienced hands like his, obviates largely the difficulties which I have found in my efforts to manage bees profitably on the non-swarming system, and where time and skill are available I recommend his plan for renovating his queens and hives to the careful attention of your readers. Anyhow he and I are co-operatives in the same field of labour under the influences which are leading to revolutionise our whole system of bee-keeping in the wholesome direction of increased profit and interest.

Having said this I return to my subject as stated at page 198. I asked, "How are we to prevent swarming so as to secure the largest possible harvest of honey?" The main answer is, Give them plenty of room easy of access, and so contrived as to allow the bees opportunity of spreading themselves out at pleasure without inconvenient crowding. An expansible hive would be the *ne plus ultra*—expansible in every direction as the summer advanced, and, of course, capable of as easy contraction in the same ratio when the busy time of year began to decline. Such a hive has yet to be invented, if indeed it be within reach of the possible. A bar-framed hive I fear it cannot be. Failing its discovery there are four methods of supplying partially the want of it, which have been all in use and variously recommended. Mr. Phillips's method of lateral expansion, to which I have recently drawn attention, is a modification of Nutt's system of three boxes collaterally placed, but a great improvement upon it because of the absence of intervening checks to continuous comb-building. I shall not further allude to it here save to express a hope that we shall hear more of it this summer. There have been and are still to be found advocates of enlargement of hive space by nading—that is to say, by enlargement downwards. I cannot say that I have given this method such a trial as to qualify me to speak of its merits. My own experience goes to prove that honey-comb constructed in a chamber beneath the hive is coarse and impure, but I do not profess to have tried any other form of nading than a box placed under the stock, through which the bees were obliged to pass in getting into the open air. Perhaps some of your readers can give us a more favourable report of this mode of increasing hive accommodation. There remains to be noticed that mode of hive enlargement which has found chief favour with apiarians of our own day—namely, expansion upwards. This is done in two ways: first, by an actually contrived sliding case moving upwards on the hive top. A hive of this sort would seem at first sight to meet a great desideratum, as affording opportunity for the gradual increase of space at the honey-gathering season according to the actual needs of the hive by a process of elevation, the super slipping over the hive like the parts of a telescope. It has been in use, I believe, in America and even in this country, but there are obvious practical difficulties in the management of it which would be likely to impede its easy working: hence, perhaps, it is that we have heard so little of it.

There remain to be noticed the various forms of supering hives by boxes or frames in endless modification, of which I need not here speak particularly; these, too, are for the most part common to all methods of bee-management, and are not specialities of bar-framed hives. I will only remark relatively to those that the tendency of improvement in this direction is to discard the use of supers of fixed size, be they great or small, and to employ sectionals—in other words, mere frames more or less slight capable

of holding one or two combs, any number of which can be used simultaneously so as to form one continuous chamber divisible at any moment either for the removal of completed combs or the substitution of empty ones. They have been commented on favourably in this Journal, and are doubtless well known to all who read this paper. I have no doubt they are the supers of the future; let us all make good use of them this year if the sun and the showers are propitious for the coming harvest of honey.

But, as I observed in my last communication, no enlargement of space however well managed will always prevent swarming. We must therefore watch carefully week by week the internal condition of the hive if we wish absolutely to succeed in baffling any such intention on the part of our bees. Nor is this a difficult matter up to a certain point in the case of bar-framists. All that is necessary is now and then to remove the top board or covering and lift the combs out one after the other. The best time for doing this I find to be early in the afternoon or late in the morning when the bees are mostly abroad and are most busy, for then the combs are often comparatively deserted, and they can be handled with the least risk of damage. If any royal cells are formed, whether tenanted or not, they can easily be cut away. Some assistant should be employed that the chief operator may have both his hands free. The necessary inspection can be done, if with dexterity, in a very short time and without any serious interruption to the full activity of the bees.

It will, of course, be obvious that if any royal cells are formed they can be utilised in various ways. To this matter I shall draw attention in a subsequent paper. I have only time now to remark that the check to swarming just detailed has, perhaps, its limit. That limit is the giving of supers. When these are in place and the storage of honey in them has begun in earnest most beekeepers had rather leave their bees alone. Yet even here a periodical examination of the breeding combs is quite possible, for it is comparatively easy in most cases to remove supers temporarily from off a hive. I have often done it myself—less so, perhaps, in the case of sectionals; but here, too, it can be done without much risk or trouble. A practised hand and a brain fertile in resources can do anything with bees.—B. & W.

SWARMING versus NON-SWARMING.—Through some verbal alterations in my remarks under the above heading in last week's Journal my meaning was obscured, in one instance reversed. The expression "which saves time and drone combs being built," was changed into "saving time in construction of drone cells." I am thereby made to recommend expediting the very thing I sought to avoid. Then, again, in my instructions for the formation of artificial swarms the all-important requisite "one frame brood" was omitted, without which the flying bees and their queen would in all probability desert, and the latter be killed on the threshold of the nearest combed hive into which they attempted to find an entrance.—A. RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

BRAHMAS LAME (T. A. J.).—Are your cripples cocks or pullets? If the former they have injured themselves, or have been injured in some way. It may be done by flying from a lofty perch, and thereby bruising the ball of the foot; or the cause may be sometimes found to be that small pieces of window glass have been thrown into the run. Small pointed pieces find their way into the ball of the foot without leaving any mark on the outer skin. This may be true of either sex, but there is a peculiar disorder to which pullets are subject at this time of year, and which may be called lameness. It is that a hen walks about in an upright position like a Penguin, and supports herself on a triangle composed of two legs and her tail. Such a patient should be at once put by herself; she is suffering from some derangement of the egg-producing and laying parts. As a rule these patients recover in a few days. The treatment is to administer purgatives. Where fowls entirely lose the use of their legs it generally arises from an injury to the back, sometimes from cramp. The latter is serious.

MANAGEMENT OF SILVER PHEASANTS (R. D.).—Remove the eggs for every reason. First the hen will lay many more if they are taken away; next, if they are allowed to remain they are often pecked by the birds and afterwards eaten. The safest plan is to put them under hens as fast as you get a sitting. Nine are enough to put under a small hen; eleven, thirteen, or fifteen under a larger one. When she has quite done laying and shows a disposition to sit let her have five eggs; but in that case you must part the cock off. This is easily done by running a hurdle or any other partition across one corner of the pen. Be careful while the hen is laying to supply her with lime, mortar, or chalky rubbish, as the lack of it is often the cause of their eating the shell of the egg already laid. Feed the young like the young of any other Pheasant. When the hen brings off her young remove the cock altogether. As soon as the young are fit to remove from the hen put them in a place by themselves. The old pair may then run together again.

TREATMENT OF WOODLARKS (R. C. M. L.).—Woodlarks should be fed as follows:—Besides German paste give poppy seed, oats, crushed hempseed, unsalted curds, ants' eggs, mealworms, and cooked bullock's heart. In spring supply small green sprouts and watercress, and even the catkins of the hazel tree; in summer all kinds of insects; in autumn poppy and rape-seed, and doddier grass and millet. Larks suffer much from a disorder in their feet, which often become much swollen. When their feet become sore anoint them with almond oil. Keep their feet free from fine threads or hairs, which frequently get twisted around and cut into the joints, and their feet becoming brittle in confinement easily break at the joints. Their legs also become very brittle, and not unfrequently they die from broken

legs. Through being caged up and debarred from their natural exercise and having an abundance of good food, whereby the blood in their system becomes thickish or semi-stagnant, this brings about a very usual malady in Larks—epilepsy. A good and speedy remedy is, when you find the Lark in one of the fits, to immerse it in cold water and cut one of its claws just into the vein so that blood may flow. This will give temporary relief. A drop or two of olive oil internally will be of service. We tell you all we know that will benefit your Lark, but which we fear will eventually die in one of the fits. If you have a spare room let the bird have the use of it to exercise in.

CANARY WITHOUT FEATHERS (Subscriber).—Deficiency of plumage to such an extent as you describe leads us to imagine that it proceeds from a gross state of the bird's system. Most likely your Canary will not entirely recover her feathers until next autumn's moult. If the skin of the bird appears scurfy rub it slightly with oil of almonds. Loss of feathers is often caused through the bird being fed upon a too heated diet and pampered with sugar and pastry. This is a mistake. Canaries should not have lump sugar to peck at. The bird may have a piece of salt instead. If you have been feeding the bird freely upon hempseed and rapeseed, substitute linseed and a few groats occasionally, with lettuce and radish seeds, and just now a free supply of dandelion. Try a cold bath occasionally, and in its drinking vessel keep a rusty nail, and now and then add to the water a little saffron.

FEEDING BEES (Tom Tower).—The hive which you have bought, measuring 18 inches wide and weighing 28 lbs., is very cheap at 25s. Though it does not require feeding, a little good syrup will keep the bees in good spirits and cause them to breed, but the quantity you now give them—an imperial pint per day—is far too much; quite enough for a week given daily in small doses. When the hive becomes full of bees and brood a pint of syrup daily in unfavourable weather will not be too much.—A. P.

REMARKS.

27th.—Snowy morning, cleared off at 10 A.M.; bright and sunny the rest of the day.

28th.—Fair, but dull morning; cold dull afternoon, snow showers; snow and sleet in evening.

29th.—Snowy morning till 0.30, afterwards fair, but dull and cold; starlight [night].

30th.—Bright sunny morning, snow showers from 1 P.M. till 2.45, sunshine for about an hour, then cloudy till 4.30, bright sunshine for an hour again; bright starlight night.

31st.—Bright sunny cold morning, cloudy and dull after 10 A.M.; showers in evening.

April 1st.—Bright sunny morning; snow showers in afternoon; fine sunset and evening.

2nd.—Bright and sunny in early morning, overcast at times during rest of the day, slight shower at 1.45, with sunshine at intervals.

A cold week, the nights being on the average colder than in any week this year.—G. J. SYMONS.

COVENT GARDEN MARKET.—APRIL 3.

THERE is very little doing just now in our market, the only alteration worth notice being the arrival of several samples of new Grapes, the general run of which are good for the time of year. Strawberries and Cucumbers are lower, other prices remain the same.

From observations taken near London during forty-three years, the average day temperature of the week is 57.6°; and its night temperature 35.9°.

DIGGING AND MANURING.

FOR the last few years I have been seriously considering whether autumn-working of land has all the advantages claimed for it, and each season my faith in it has been shaken more and more, and now for the future, on my heavy soil at least, I shall not fret if none of it is dug before March. One great drawback to spring digging has always been the fancied necessity for getting crops in early, but since it is proved beyond dispute that better Parsnips, Onions, &c., can be grown on heavy soil if the sowing is deferred till the middle of April than if done earlier when the soil is not in a suitable condition, matters are considerably simplified and labour economised.

The principal objects of digging I take to be—1st, Making the soil permeable to air and water, easier to plant and easier for the roots to ramify. 2nd, Burying manure and weeds. 3rd, Changing the soil which has been cropped for that which has not, or mixing the two together. As regards the first, aëration is very imperfect if the soil is at all wet when turned over, and still more so if rain follows immediately after. Even if the digging is done in late summer before the heavy autumn rains the interstices on the surface are filled long before spring, and the loose soil below holds much more water and consequently takes longer to dry than that which has not been dug.

As for autumn-manuring, I do not know that it has any special advantages. It certainly has some disadvantages, inasmuch as it harbours slugs and worms, it also keeps the soil wet, and consequently prevents it becoming sweet. If it is argued that manure lying about all winter loses much of its value, then I say mix an equal quantity of soil with it, and it will improve instead of deteriorating.

The best plan I consider for heavy soil is to take the first opportunity in spring when the surface is moderately dry to break it up roughly, let it be baked by the sun and wind, and then when it becomes just so dry as to bear trampling on without binding, manure it, turn it over, and plant at the same time. If for sowing, draw the drills as the digging proceeds, and allow them to remain open for a few hours to get aired.

The best steel forks are far preferable to spades for ordinary digging, and I am pleased to say my men have at last taken to them kindly, and spades are at a discount.

There is another object in digging besides those named above which is gained when the sun becomes powerful—viz., raising the temperature of the soil. For tender plants and others which are required to grow quickly much is gained by turning over the soil several times, as it becomes dry and warm on the top. On the other hand, digging in frost, snow, or even wet soil, does an amount of injury which takes weeks and sometimes months of sunshine to remedy.—WM. TAYLOR.

WATERING ROSES.

I HAVE been asked by a Rose-loving reader of the Journal to write a few lines upon the important subject of watering.

No. 300.—VOL. XXXIV., NEW SERIES.

Now there is no subject on which rosarians differ more than on this point. Whether we consider the practice of exhibitors or non-exhibitors, people who grow thousands of plants with the sole object of exhibiting them, and those who have a few dozen garden Roses, all alike have their theories, and those are not only conflicting, but diametrically opposed to one another. It is no use saying that such and such great exhibitors water their Roses every night; the answer comes most readily, "But So-and-so, an equally good rosarian, never waters." Let us take instances: Mr. Jowett of Hereford, the champion last year, or at least the winner of the champion cup at the National, waters his Roses every night. He presses in all availing hands to water, and if a tramp or vagrant comes begging with the old story, "We have no work to do," "Work! I will give you work and pay you well too. Come and water my Roses." And it would interest your readers to know how many men and how many hogsheads of water were poured on the plants that produced those blooms at St. James's Hall.

On the other hand, an equally great rosarian, once a neighbour of his, now, alas for us! gone to that land where

"Everlasting Roses blooming
Make an everlasting spring"—

one of the most ardent lover of Roses, the late George Arkwright—never watered. He lived on a hill where there was scarcely any water, and he knew that once to begin watering and then to leave off was a most fatal course, so he never began. In like manner the greatest rosarians among the nurserymen are equally opposed to one another in their treatment of their Roses in this respect.

Mr. Keynes could only water a few standards, and the bulk of his Roses were left as dry as a cinder-heap in August; while Mr. George Paul has the New River running right through his nursery and can flood his place with water. Mr. Cant, *nulli secundus*, has only a little ditch running through his place, but in order to make the most of it, dams it up at different parts of his nursery. He then, for the double purpose I suspect of keeping off marauders, and of doctoring both Roses and thieves, sinks a lot of sugar oaks and tubs in his ground so that they are level with the soil, fills them half up with manure, and fills them with water from the ditch, but in this way he can only water a few of his very best.

Mr. Baker waters every night. His system is somewhat similar to Mr. Cant's, only his tubs are placed on stands. He has reduced watering to almost the standard of one of the fine arts; at least he combines the greatest excellence of material with the most delightful ease. He has the water laid on from the city works all over his garden; his tubs also line the rosery, and are filled with his own particular mixture, which is a secret I do not divulge (without leave at least). During the day the water is running into the tubs, and by evening his own particular brew is all ready. Hoses are attached to the tubs, and along each line of Roses nimble feet run watering each plant with the greatest ease and certainty of wasting no drop of the precious liquid.

I have spoken of watering, and, with the exception of

No. 1641.—VOL. LIX., OLD SERIES.

Mr. Baker's and Mr. Cant's method, yet have said nothing of the mode or kind of watering. Some persons, no doubt, think any kind of watering is good. To this I demur. There is one kind of watering which is positively deleterious—I mean employing cold spring water; and why? Because you give the plants a sudden shock. It is like icing a tropical plant all the day long exposed to the hot midsummer sun, when suddenly down comes a flood of cold spring water poured out upon them. Can anyone doubt that such a course is sufficient, if not to kill at least to send the Roses into a galloping consumption? Let the water, if not rain water, be exposed to the sun all day, and let some kind of fortifying matter be added, and then you will do good, but not otherwise.

Now as to the fortifying matter. First of all comes guano. What of it? Well, I am confident from my own experience and from discussing this matter with others that there is no greater mistake than the indiscriminate use of this powerful manure. When used, and only then with the greatest care and caution in the smallest quantities, it is most serviceable, but otherwise is fatal in its effects. I lost last year plants to the value of £100 from the stupid plan of letting a boy put the guano on. I had given him strict directions how to do it, but he put enough on to burn up every plant in the collection. If you use guano it is much safer—in fact I am inclined to think it the only safe plan—to use it in a liquid form. Mr. Cranston does not believe in it, and he does not use it. He has over and over again instilled on me the principle of using it only with the greatest caution. My friend Canon Hole in his amusing book on Roses speaks of some plants which, like Gloire de Dijon, will do anywhere. Give them, like an Irishman when sent on a journey, just a hint of whisky—just a slight tingle of the lash, the least stimulant in the form of guano at the growing time of the year, and then discard it for the season.

We now come to the next watering material—liquid manure. Here we have the most valuable of all stimulants, manure applied at the most critical time in the most soluble form. Nothing can be so useful, and no money can be more usefully expended by the rosarian than in buying the materials for liquid manure. So convinced am I on this point that I am going to try this year without manuring in any other form than this. Instead of spending a large sum on stable manure I have built another tank. The practice of laying manure on the surface of the ground is so extravagant, so wasteful, and to me who live so far from a town so ruinously costly, that if I cannot do without it I must leave Rose-growing alone.

I now come to the various kinds of liquid manure which are beneficial. The best and strongest I believe to be, where it can be procured, sheep droppings placed in a tank of water and left to stew for a week or so; then the water may be renewed all the season, and I do not think the virtue of the manure will have been exhausted. But the difficulty of procuring this manure is very great, as naturally farmers do not like to part with this most fertilising matter without a decided *quid pro quo*, and most persons refuse whatever quid you may offer them. Here a man like my friend Mr. Jowett has an immense advantage as in other matters, for he has a large farm of his own and all kinds of manure at his service.

Next to this in value and importance comes, in my opinion, night soil, and this is a manure which can be obtained at the simple cost of making tanks. It is true that tanks are expensive to make, but when once made they will last at least an ordinary Rose-grower's life. I have lately made them of wood (red deal), and although I have only had three years' experience of them, yet I have found them so far watertight and to answer all my purposes. The cost of one to hold about twenty hogsheds when completed, including excavation of the earth and fixing, is about £20. The tanks are buried in the ground, with a trap door through which you can obtain the stuff and also introduce any guano or other manure that you may feel to be advisable to use. Of course people who live in towns or under Boards of Health, &c., cannot do this, but then they have the great advantage of being able to buy all kinds of manure cheap without having, as in my case, to pay as much for cartage as for the manure.

After night soil, liquid manure made from the cleansings of pigstyes is the next best, and to this may well be added soot. There is no question that soot is a most valuable fertiliser for Roses. Nothing gives so brilliant a colour to the blooms as soot. There are many other manures, such as superphosphate of lime and other artificial kinds, but these I have not tried yet, so shall give no opinion of them. I have given the results

of my experience in this article, and offer it to your readers. —WYLD SAVAGE.

CELERY CULTURE.

EARLY last year in Nos. 830 and 835 of the *Journal of Horticulture* two correspondents, "A. H." and "A NORTHERN GARDENER," strongly recommended the practice of transferring the young Celery plants direct from the seed bed or boxes to the trenches. "A. H.'s" practice is "to sow thinly in pans or boxes in gentle heat, and as soon as the plants are up removing to a cold frame and gradually hardening them off to the end of April, at which time they are placed outside, so that they may be ready for pricking-out into the trenches about the middle of May." The following is "A NORTHERN GARDENER'S" practice, which I certainly prefer:—About the first week in April the heating materials (leaves and manure) previously used for forcing Seakale and Rhubarb, is collected and shook into a heap, adding a few barrowfuls of lawn mowings, and water if required. This, when sufficiently heated, is levelled; a frame easily made of common boards is put on, and a few inches of rich soil spread over it. The soil is well watered; the Celery seed sown thinly and slightly covered with fine soil. Straw covers are placed over the bed, which remain on till the seedlings appear, after which all the light and air possible consistent with safety is admitted. Water is freely administered, and the plants are well thinned out in order to obtain sturdy plants, which are in June transferred to the trenches to perfect their growth. The latter practice is far from being new, an acquaintance of mine having long successfully followed it, not only with Celery, but also (as recommended by "A NORTHERN GARDENER") with many kinds of bedding plants, including Pyrethrums, Lobelias, Stocks, Asters, Zinnias, &c.

Last year I adopted the plan of sowing my main crop of Celery in a similar manner, but a fortnight earlier than recommended by "A NORTHERN GARDENER." At the time of sowing I did not intend transferring direct to the trenches, but the remarks above summarised induced me to do so. When raising kinds of plants that require to be removed I find it advisable to use sifted soil (which is obtained from an old rubbish heap) for the seedlings to root in, as well as for covering the seed. We also used some of the sifted soil when planting in the trenches. This was done by drawing a drill through the centre of the prepared trench and filling it in with the light soil previous to planting. Owing to limited space we planted double the number of plants required in the trenches. When the other trenches were ready every other plant was taken out with a trowel and transferred to its fresh quarters, filling up the holes left with soil. This I find far less trouble, and the plants are far less liable to suffer from drought than are plants pricked out into shallow beds on a hard bottom. They were never shaded, were watered overhead in the evenings of dry days, and occasionally a good soaking was given them till well established. We experienced a very dry summer, and the Celery fared badly for water, two good soakings of liquid manure being the most given. The result far exceeded my expectations, as all through the winter we have had plenty of extra good Celery, and that, too, in a garden notoriously bad for keeping it. I do not say that the above method of culture was the sole cause of success in keeping it, but it contributed largely towards it, for Celery well but not overgrown is undoubtedly the best for keeping; the growth being thick and well matured proves a better protection to the heart at earthing time, and also against the inroads of slugs, &c., than is the case with weakly-grown plants. "Bolters" were few in number, which was not the case with Celery grown on the old system. On lifting some of the best plants I was surprised to see the quantity and size of the roots. These had spread far out into the trench, thus rendering the plants to a certain extent independent of external influences. If following the above practice, before earthing-up see that no suckers remain on, as they seem more liable to produce them in quantity when so grown. The Celery we are using now was sown the third week in April, and of course is much smaller than the main crop. The final earthing of the late crop was deferred till late in November, a dry time as possible being selected for the operation. After having tried and seen tried in various parts of the country the plan of having two or more rows in a trench, I have decided to fall back on the single-row system, believing it to be the best.

The spaces between the Celery rows should be utilised for growing early and second early Peas, unless, as in my case, the neighbourhood be exceptionally dry, and also for Kidney Beans. The latter are largely grown by the market growers between their Celery rows, and when so grown appear to be unusually prolific. Lettuces also do well in this position, especially if sown in drills and thinned-out. When these spaces are to be cropped it is a good plan to dig them nearly up to the intended trenches, and this, with the soil from the trenches, will give a good depth of soil, the advantages of which are obvious.

The varieties of Celery which I prefer are Suttons' Solid White for the early crop, Osborn's Select Red for succession, and Major Clarke's Solid Red for main and late crops. Osborn's is a good solid variety, and kept well till the end of February, but Major Clarke's is the favourite here.—W. IGGULDEN.

CULTURE OF BOUVARDIAS.

WHITE flowers are always in great demand at all seasons of the year, but more especially during the winter and early spring months, and no class of plants can furnish a more constant and acceptable supply of them better than Bouvardias. The present is the best time to strike the cuttings, which the old plants will supply after they have been cut back after flowering. The cuttings will strike readily in a brisk moist heat, after which they should be potted into small 60-pots in a compost of two parts of fibry loam and one of leaf soil, with a little silver sand added. The stopping of the shoots must be well attended to in order to form compact plants. After they are well established they must be inured to a cooler temperature and receive more air. When they have made small bushy plants plant them out into a turf pit or cold frame in two parts loam, one of leaf soil, and one of well-decayed cow manure. Keep them close for a few days until they are well established, syringing them well and closing the frames early with sun heat. When they are in full growth more air must be given, and eventually on fine days draw the lights off entirely. From the beginning of June until the latter end of August the plants only need the protection of glass during cutting winds and heavy rains. Each plant at intervals must have the roots cut round to within 4 or 5 inches of the stem to keep the plants within bounds. Stopping must be discontinued by the first week in August, or sooner if the flowers are required early, and the plants must be lifted carefully so as not to disturb the balls, and be potted into different-size pots according to the size of the plants. Keep them close until they are established, when they may be introduced into heat as required, about 60° to 65° at night. If they are not kept in heat during the winter they do not bloom so freely; in fact, when they are kept in heat, as soon as one crop of flowers is off another will soon take its place. After the blooming season is over cut the plants well back and treat the same as the preceding year. B. Vreelandii for a white and B. Hogarth for a red I have found to be the most useful varieties, as they are dwarfer in growth and keep longer in a cut state than the slender-growing sorts. For bouquets in winter no flowers are more popular than those of Bouvardias, and I know of no mode of culture by which they can be provided with more ease and certainty than by the plan now recorded.—A SOUTHERN GROWER.

VEGETABLE CULTURE.

CHAP. XIV.—THE TURNIP.

THE Turnip is a native of Britain. It is one of the oldest and easiest cultivated of garden vegetables. In small gardens it is, as a rule, only grown during a few months in summer, but in most large gardens it is necessary to have a supply of Turnips all the year round, and this can be secured with very little difficulty. In all gardens the seed for the earliest crop may be sown from the middle to the end of March. In exceptional instances seed is sown before that time both in frames or in the open air with some fermenting material under the rows, but these means do not generally repay for the trouble required to carry them out properly. Seed sown at the end of March will produce roots fit for use by the end of May or beginning of June. About the end of May and early in June the plants soon run to seed, even when sown so late as the end of March; consequently it is very important, if a succession has to be kept up, that seed be sown frequently during April. Every ten days during this month is not too often to sow a small or large patch according to demand. During May and for the following three

months a patch should be sown every three weeks. When sown in August the plants do not bulb until far into winter or the following spring, and this is just what is desired to give a supply as near as possible up to the time the spring-sown crops come in.

The Turnip does not succeed well in a stiff clay soil, nor yet in one very sandy, but it does well in a moderate light soil. In this with plenty of manure the bulbs swell freely and do not seed so rapidly as when grown in a hard soil. As the Turnip grows quickly the manure used for its culture should be well decomposed when it is applied, or little of it will be utilised before the crop is matured. This is particularly the case with early Turnips, as they grow much faster and are not so long in the soil as those sown to stand the winter. The ground on which Turnips are grown should be of fair depth, especially if the soil is light, as a light and shallow soil combined has an invariable tendency to produce roots both stringy and hot. These never find favour in the kitchen, and care should be taken to sow Turnips on ground cool enough and sufficiently rich to produce fresh sweet roots. Previously to sowing the seed the ground should be dug over and be made fine on the surface with a fork. The seed may be sown broadcast, but we prefer it in rows and always adopt this plan. Drills are drawn 15 inches apart and about 1½ inch deep, and the seed is covered over with a little of the finest of the soil. In cold stiff soils a quantity of old potting soil should be used to cover the seed. The earliest crop may be sown on a warm border, summer crops in a cooler position, and the latest crops on a south border again. We sow our latest on the ground cleared from early Potatoes, and then the soil is only levelled down and the seed sown without digging the ground. When the young seedlings are just coming through the soil, and until they form a few rough leaves, a sharp look-out must be kept for the Turnip beetle. This insect is well known to both gardeners and farmers. The insects quickly destroy the whole of the young plants when once they begin to eat them; but the slightest indication of their presence should be the signal for dusting the whole of the plants with lime or soot, which are both excellent preventives when applied in time. The beetle is most destructive in dry weather. As soon as the rows can be seen the Dutch hoe must be run deeply between them, and when the plants are fairly into the rough leaves they should be thinned-out to 3 inches apart. When they again begin to meet in the rows they must be thinned-out to 8 or 10 inches apart, and at this distance good roots will be formed. No weeds should be allowed to grow amongst the plants at any time, and to keep them down and the soil free and open the hoe must be used frequently.

Where the roots do not remain in a good state of preservation in the open ground during the winter they may be lifted and stored like Carrots in a dry shed, or they may be laid in small ridges and thatched over in the open ground. Snowball and the American Strapleaf are good early sorts. Early Selected Stone and Red American Stone for main crop, and Orange Jelly, Chirk Castle, and Sutton's Green Globe for winter culture.—A KITCHEN GARDENER.

JUDGING ROSES.

JUDGED by his own words "WYLD SAVAGE," as the champion of small r. large Roses, must now own that he is pleading not for what is best in itself, but for that which he, and others like him, can best produce; for in saying that the soil of the advocates for medium-sized Roses is not so strong, rich, and well adapted for Briar Roses as that of us northerners who grow grander blooms, he distinctly lets his cat out of the bag and throws up the sponge.

If we, according to "WYLD SAVAGE," have the best habitat for the Rose, and such habitat produces larger blooms than the Wyld Savage growths of the environment of the southern counties, which we are told is miserable soil—a bed of stones, it is not to be denied that size is an evidence of superiority; for if ours are the more favourable conditions, and the result is increased size of bloom, it is queer reasoning to maintain that smaller blooms as the result of less favourable conditions are superior to large blooms.

My fellow midlanders and northerners will no doubt join with me in deeply sympathising with the difficulties both floral and logical of our southern friend, but we can hardly consent to adapt our views to his necessities.

Mr. Jowett, Mr. George Paul, and Mr. Cant will hardly thank "WYLD SAVAGE" for instancing them as supporters

or growers of medium-sized Roses. Mr. Jowett's stand of forty-eight at the National last year was full of magnificent specimens, and he will know better than to meet his competitors this season with small blooms, for Mr. Cranston's grand cup will follow the grandest Roses. As for Mr. George Paul and Mr. Cant, one has only to look at their stands and their catalogues to see the most complete refutation of the idea that they are advocates of medium-sized Roses for any other purposes than the border, the bouquet, the coat lappet, or the sentimentalist's offering.—E. N. POCHIN, *Barkby Vicarage, Leicester*.

THE BOTANICAL AND HORTICULTURAL SOCIETY OF DURHAM AND NORTHUMBERLAND.

THE spring Exhibition of this old-established and rejuvenated Society was held in the Town Hall and Corn Exchange, Newcastle-upon-Tyne, on the 3rd and 4th inst. The sum of £185 2s. 6d. was offered in prizes, the number of classes being ninety-two. Every description of flowering plants cultivated in gardens or greenhouses, and that can be had in flower at this season, has been included in this comprehensive schedule. The Show held this year was in comparison with that of 1877 much superior both as regards the number of exhibitors and the quality of the plants exhibited. The prizes were so liberal and the exhibitors receive such kind and courteous treatment from the executive, that it naturally follows, not only that a large number of plants should be forthcoming, but that they should increase in quality and numbers every year. The canny Newcastle folks evidently mean to make their exhibitions second to none. The Committee headed by W. J. Taylor, Esq. and J. H. French, Esq., Honorary Secretaries, seem to work most harmoniously together. All of them are ardent lovers of flowers, and their work is to them a labour of love. In noticing the Show it will be convenient to group each class of plants by themselves.

GREENHOUSE PLANTS.—Of Azaleas there were a few fairly good specimens, but they were not quite so well grown as they might have been, and the varieties are not of the most recent introductions. For four Azaleas, Mr. George Stockley of the Elswick Park Company gained the first prize with specimens trained as pyramids. Mr. M. D. Thompson, gardener to Lindsey Wood, Esq., South Hill, was second; and Mr. H. Wright, gardener to Grosvenor Talbot, Esq., Burley, Leeds, third. Four stove or greenhouse plants, Mr. H. Wright had by far the best; his specimen plant of *Imantophyllum minimum grandiflorum* was as fine as any we have ever seen, it had seven superb heads of bloom. A plant of *Phajus grandifolius* had six good spikes. The other two were a basket of *Dendrobium nobile* and a fairly flowered *Epacris*.

Camellias were represented by specimens from 3 to 5 feet in height, with clean healthy foliage and full-sized flowers. Mr. G. Stockley and Mr. H. Wright had the best. *Epacris* were not shown in good condition; the plants though large showed signs of exhaustion, and the same remark applies to the *Heaths*. *Genista fragrans* made a very fine feature in the Show; a row of plants from 8 to 6 feet in height was very conspicuous. Mr. Robert Turnbull, gardener to George Luckley, Esq., Jesmond Grove, had the best plants, and an excellent specimen was sent by Mr. M. Larke, gardener to the Rev. R. F. Wheeler, Vicarage, Whitley.

Forced hardy shrubs including *Rhododendrons*, *Deutzia gracilis*, &c., deserve a passing notice. *Rhododendrons* were represented by large well-flowered specimens. And here again it would be to the advantage of exhibitors if they were to obtain some of the more recent varieties. The prize specimens were but little removed from the common *ponicum*. The specimens of *Deutzia gracilis* were large and well-flowered dwarf bushes. Those that gained the first prize were really splendid. Mr. Thos. Battensby, Blaydon, was the prizewinner.

Cinerarias, for which a number of classes were provided, were very well grown, and to show the extent of these it may be stated that seventeen collections were staged. Mr. A. Methven, gardener to T. Lange, Esq., Heathfield House, Gateshead, was first for six. His plants were large with healthy foliage and finely developed flowers. Mr. W. James, gardener to J. G. Riddell, Esq., Swinburn Castle, was a good second; and Mr. H. Wright third with small but well-grown specimens, some of the flowers being quite 2 inches across. Mr. T. Haig, gardener to Thomas Adamson, Esq., Springfield, also gained a first prize, but space forbids us giving the details of many good collections.

Cyclamens in collections were fairly well grown, the highest honours going to Mr. T. Wilson, gardener to Mrs. Fleming, Normanby Hall, Middlesborough; Mr. J. Hutchinson, gardener to J. J. Hunter, Esq., Whickham Grange; and Mr. T. Battensby. A row of the Lily of the Nile (*Calla æthiopica*) made a good show, and Mr. W. Middlemas had the best examples. Zonal *Pelargoniums* were very good for the season. Edward Adams, Esq., Swallow, had an excellent specimen of a white-flowered variety with at least thirty fine trusses, and the Rev. R. F. Wheeler's gardener, Mr. Larke, had the first prize for two plants.

Primula sinensis were very fine indeed, and many excellent collections were staged. Mr. G. Stockley, Mr. W. Charlton, and Mr. W. L. Thompson of 87, Stanhope Street, had the best. There were also a few Roses in pots. We would strongly urge our Newcastle friends to give considerable attention to these, as no plants can be more attractive at a spring show. Mr. T. Wilson gained the first prize; Mr. E. H. Bradley, gardener to T. S. Turnbull, Esq., High Barnes, Sunderland, the second; and Mr. E. Adams the third. That fine herbaceous plant *Dielytra spectabilis* well deserves a meed of praise, especially the single specimen sent by Mr. T. Battensby. Mr. W. L. Thompson showed six fine plants, and Mr. A. Methven was first for two. The class for *Spiraea japonica* was a well-contested one, the plants being of moderate size but well flowered. Mr. H. Wright gained the first prize, Mr. J. Hutchinson second, and Mr. W. Alexander, jun., Hexham, third. Lily of the Valley was represented by seven collections not one of which but was worthy of a prize. The large pots from Mr. John Thompson, Ravenside Nurseries, were really splendid, though not at their best on the first day of the Show. Mr. H. Wright and Mr. T. Wilson also competed. Mr. J. Thompson and others had also some nice pots of *Scillas*. Mr. J. Hutchinson, E. Adams, Esq., and Mr. J. Brogden, gardener to Mrs. Morrison, Jesmond Park, had fine well-flowered pots of *Mignonette*. The six well-flowered pots of *Myosotis* from William Lawes, Esq., of Ponteland did not fail to command admiration. A bank of the common Wallflower, spreading around the most delicious perfume, was much admired; certainly we never saw finer plants before than the six exhibited by Mr. G. Stockley. They were examples of skilful culture, the spikes strong, foliage perfect, and flowers $2\frac{1}{2}$ inches across. Mr. Stockley also gained the first prize with German Wallflowers. Other exhibitors were Mr. J. Gardener of Swallow and Mr. A. Methven.

Auriculas.—Of these there were eight collections, but whether it is that good sorts are scarce or that the Show was too early for the flowers we know not; certain it is the exhibitors must have been driven hard to make up their lots, as some of the flowers were pin-eyed and others were not in character. E. Adams, Esq., and Mr. J. Garret, jun., of 85, Newgate Street, had the best flowers.

Polyanthuses, on the other hand, were very fine indeed, and great praise is due to Mr. Henry Sanderson of Whalton for the admirable manner in which he staged his plants. He had two noble examples of George IV. (Buck), with flowers nearly 1½ inch across; Lancer (Bullock), Exile (Crownshaw), Formosa (Barnard), and William IV., a flower of his own raising. Mr. W. Hedley of Whalton was second, and Mr. R. Atkinson third. For three pots Mr. Sanderson was again first, Mr. R. Atkinson second, and Mr. J. Bilclough, Winlaton, third.

Pansies in pots were healthy clean-grown examples. Mr. Sanderson was first with Col. Muir, a fine dark self; Mrs. Ramsey, white; Robert Burns, yellow ground; Lavinia, white ground; Isaac Craig, white ground; and Tom White, yellow ground. Mr. R. Atkinson was second, and Mr. J. Gardener third with six fine pots of Cloth of Gold. Six fine pots of Daisies from Mr. M. Larke gained the first prize, Mr. R. Atkinson was second, and Mr. W. Spoor, jun., Swallow, was third.

HYACINTHS.—These were the principal feature in the Exhibition, and they were very well grown in some cases; but an objection might be made to the practice of showing three bulbs in a pot. To do this well no exhibitor would venture to show them in the pots in which they were grown, as it would not be possible to get the spikes uniform in that way. We think it would be better to offer prizes for thirty-six Hyacinths in the same number of pots. For thirty-six Hyacinths, three bulbs in a 7-inch pot, Mr. W. J. Watson, The Hall Nurseries, Penham, was first. His spikes were uniform in size, and the bells very fresh and well arranged. Some of the best, though all were good, included *Ida*, single yellow; General Pelissier, King of the Blues, Macaulay, and Von Schiller. Mr. J. Thompson was a very close second, and amongst other fine spikes were excellent examples of *Koh-i-noor* and *La Grandee*. Messrs. H. Dewar & Co., 97, Grey Street, were third; and Messrs. S. Nairn & Son, Pilgrim Street, fourth. For twelve Hyacinths Mr. J. W. Moorman, gardener to the Misses Christy, Kingston-on-Thames, was first with spikes similar to those he exhibited at Regent's Park, London. Mr. J. Thompson also gained a first prize for twelve Hyacinths; and Mr. Moorman was first for six. Double Hyacinths were also invited, but they did not make a striking display. The best double sorts were not shown. We would advise the exhibitors to procure such sorts as *Koh-i-noor*, Garrick, Laurens Koster, Van Speyk, Lord Wellington, Louis Philippe, and Blocksberg. Except *Koh-i-noor* these are not expensive. Mr. C. Wass, gardener to M. Anderson, Esq., was first; Mr. A. Methven second; and Mr. T. Wilson third for six.

Mr. Moorman had by far the best single Tulips. Mr. W. J. Watson was second, and Mr. J. Thompson third for nine pots. For six Mr. Moorman, Mr. T. Wilson, and Mr. A. Methven had the prizes in the order of their names. The plants sent by Mr. Moorman were greatly admired, and they were safely returned by the officials of the Show. *Polyanthus Narcissus* were exceedingly well grown, and surpassed those exhibited in London. Mr. J. Thompson was first with splendid pots of Grand Monarque.

Gloriosa, &c.; Mr. A. Methven was second. In the class for three pots Mr. A. Methven and Mr. C. Wass gained the awards. It may be as well to state that thirty-four collections of Hyacinth were staged in competition.

Cut flowers, bouquets, epergnes, table plants, &c., were staged in a room together, and they made an excellent display, attracting great crowds of visitors. Cut blooms of Camellias were very good. The best came from Mr. H. Wright: he had a pale pink flower very fine, a sport from *Mathotiana alba*. Mr. J. Brown, gardener to E. Joicey, Esq., Whinney House, was second, and Messrs. James Gellender & Sons, Grey Street, were third. Trusses of Azaleas were well shown, but the best collections were disqualified owing to their being shown in bunches. Cut Roses were very good. Mr. J. Jupp, gardener to R. Brown, Esq., Bentinck Terrace, was first with very fine *Maréchal Niel*. Mr. W. Hedley and others showed fine blooms. Mr. E. Lazenby, gardener to Mrs. Gurney Pease, Woodside Gardens, Darlington, had the best trusses of *Rhododendrons*. The best single vase or epergne was shown by Mr. M. D. Thompson. It was not so elaborately arranged as some of the others, but it certainly displayed the most taste. The trumpet-shaped vase at the top was filled with Orchids, pink zonal *Pelargonium*, and *Begonia nitida*, with fronds of *Lygodium scandens* hanging down to the tablecloth. The base and centre was composed of *Pelargoniums*, *Eucharis*, and *Astilbe barbata*. There were eight vases in competition, the other prizewinners being Mr. W. Ison, gardener to W. Grimshaw, Esq., The Cedars, Sunderland; and Mr. E. H. Bradley, gardener to T. S. Turnbull, Esq., High Barnes, Sunderland. There were four competitors in the class for ladies only. Mrs. Ramshaw, Dryburn, Durham, gained the highest award with an attractively arranged vase. Mrs. Webster was second, and Mrs. Gellender third.

Hand bouquets were numerous and very good, especially in the open class. There were sixteen competitors. Messrs. Nairn and Sons were placed first, and the bouquet was very tastefully arranged. It was made of Roses, one white Camellia, white Lilac, double white Primula, Lily of the Valley, and *Odontoglossum Alexandræ*; the second-prize one was also very good, from Mr. H. Wright; Mr. C. Masters, Sunderland, third; Mr. T. Ramshaw, gardener to Mrs. Wharton, Dryburn, Durham, was fourth; and Mr. H. Atkinson, Sunderland, fifth. Mrs. Ramshaw had the best bouquet in the ladies' class; Mrs. Crament, Sunderland, second. There were also many good button-hole bouquets; Mr. C. Petty of Bishop Auckland was first, Mr. T. Battensby second.

Six plants for the dinner table brought out seven competitors, the best examples coming from Mr. H. Wright; Mr. W. Kershaw, gardener to Thos. Gray, Esq., of Spital Hill, being second; and Mr. M. D. Thompson third. Beautiful skeletonised leaves, &c., were shown by Mr. E. H. Hodgkins, of 86, Hyde Grove, Manchester; wax flowers by Mrs. M. A. Lederthong, 71, West Street, Gatehead.

The buildings where the Show was held were thronged with visitors. £250 was taken at the door against £67 last year; 1000 subscribers' names were registered at the spring show last year. The number of subscribers now amounts to 4500. During the Show 250 new members were enrolled by the Secretary. The number who paid for admission was 5000, and it is estimated that 16,000 attended the Show on the two days. We hope the Committee will obtain, as they deserve, success.

GHENT INTERNATIONAL EXHIBITION.

The following particulars of the Show were delayed in transit, and did not reach us in time for publication last week.

NEW PLANTS.—We will first refer to the cream of those staged by our countryman Mr. Wm. Bull of Chelsea, who took the first honours in every class; and we feel constrained to commence with the grand and unique Palm called *Pritchardia grandis*, which certainly must always take first rank wherever this noble order finds admirers, and we hope soon to learn that young plants are obtainable. When better known we think this may prove to belong to an entirely new genus. Another handsome and distinct-looking Palm is *Martinezia Roezlii*, with large, broadly oblong, bifid leaves, the petioles being clothed with a spiny tomentum: the name is only provisional, and we imagine it ultimately may prove to be a *Bactris*. Of the following we can offer no opinion, as the specimens shown had not sufficiently developed their characters, but they bid fair to become welcome additions to our plant houses—*Geonoma Bluntii*, *Cyphekentia macrocarpa*, *Drymophloeus paradoxus*, and *Kentia Wendlandii*. Of Ferns several handsome examples were exhibited, the most notable being the rare, beautiful, and strange-looking *Dipteris Horsfieldii* mentioned so admirably by Wallace in his records of a journey to Mount Ophi, and we hope soon to see its grand companion *Matonia pectinata* an inhabitant of our houses again. The graceful *Davallia fijiensis* must be looked after by all pteridologists. *Alsophila undulata* is a Fern of great beauty, whilst those who love variegation will do well to secure *Lastrea aristata variegata* which hails from Japan. In *Doodia aspera multifida* we have an example of a somewhat stiff-habited species producing elegant tassels on the apex of the fronds, which adds materially to its

grace and beauty. *Sadleria cyathoides*, a small-growing Tree Fern, must become a general favourite both on account of rarity and beauty combined, two qualities which do not always go hand in hand.

Amongst Cycads the rare and curious bipinnate *Bowenia speculabilis serrulata* stands first, whilst the pinnate *Zamia princeps* is in no way behind in its own style of beauty. Several other attractive species were staged, but want of space prohibits a complete enumeration. We should, however, specially recommend these plants to amateurs; their beauty is massive, and they do not soon outgrow limited accommodation. Of miscellaneous plants the most striking were *Dieffenbachias reginae*, Shuttleworth, and splendens, all compact in habit and with beautifully variegated leaves; *Anthurium Veitchii*, the curiously long plaited leaves being very distinct; *Dracæna Goldiana* and *Carludovica Drudei* which still maintain their attractions. Besides the beautiful hybrid *Dendrobium Ainsworthii* which secured the first prize for Mr. Bull, the only other new Orchid shown was staged by Messrs. Wm. Rollisson & Sons of Tooting; it was in their large collection, and was named *Dendrobium nobile Rollisoni*. The whole of the sepals and petals were an intense rich crimson purple—the richest-coloured member of the whole genus.

M. J. Linden of Ghent staged some extraordinarily beautiful varieties of Bromeliaceous plants under the name of *Massangea Lindenii* varieties; these have much in common with *Tillandsia muscica*, but the peculiar tessellations in the leaves are more vividly defined. *Cespedesia Bonplandi* is a *Theophrasta*-like plant, devoid of the coarseness in habit usually seen in the members of the latter genus, and will in all probability become a general favourite. In this exhibitor's collections were many *Dieffenbachias*, *Aralias*, and *Anthuriums*, striking in character and suitable for very large collections. Several Palms of great promise were also exhibited, but very few had attained their true character. In *Kentia Luciani* we fancy we recognise the plant figured in the "L'Illustration Horticole" under the name of *Kentia gracilis*, and shall be glad to see it again when better developed.

M. L. Van Houtte also exhibited a large number of novelties; the most striking were *Caladium Souvenir de Louis Van Houtte*, *Anthurium Warocqueanum*, *Goodyera Rollisoni*, *Nephrolepis Duffii*, and *Dracæna Robinsoniana*, most brilliantly coloured. Many good plants came from the establishment of M. Aug. Van Geert, most of which, however, are familiar to English plant growers; the bold-growing *Heracleum Frederici* fol. var. being an exception. In the collection of M. Jacob Makoy & Co. were three dwarf-growing *Marantas* in the way of M. *Massangea*, but scarcely so desirable, named respectively *Kerohovii*, *Morreni*, and *Pierardi*, but a bold and handsome Stag's-horn Fern named *Platycerium Hilli* deserves special notice.

ORCHIDS.—These plants would have been very badly represented had not the Messrs. W. Rollisson & Sons of Tooting been to the fore. This firm staged two collections of Orchids—namely, twenty and fifteen, in all probability the finest ever set up in any exhibition in Belgium, and indeed they would have required a very fine lot to have wrung the honours from them at the best shows in England. These two collections were awarded the first prizes by acclamation. Amongst them we noticed grand specimens of *Cypripedium villosum*, *Dendrobium Wardianum*, *Cattleya citrina*, and *C. Trianae Atalanta*, *Vanda Rollisoni*, *Dendrobium cambridgeanum*, *Odontoglossum gloriosum*, and *O. Alexandræ*; *Lycaste Skinneri*, *Masdevallia Lindenii*, *Dendrobium luteolum*, *D. fimbriatum oculatum* and *D. crassinode*, *Cypripedium Lowii*, *Odontoglossum Cervantesii*, and several others. In Messrs. Rollisson's collection of the beautiful and now exceedingly rare *Anæctochilus* and *Goodyeras*, and which received the first prize, a fine specimen of *G. Rollisoni* was noticeable; it was also shown in a small state by M. L. Van Houtte in his collection of new plants. This collection of Orchids was increased in interest by the grateful perfume which pervaded them, produced by the introduction amongst them of a plant of *Boronia megastigma*. This was immediately detected by both the King and Queen, and Mr. T. R. Rollisson had to bring the modest-looking but deliciously perfumed plant forward for their Majesties' inspection; the Queen and the Countess of Flanders were afterwards graciously pleased to accept from the exhibitor a plant each, since which *Boronia megastigma* has been in great demand. M. *Massange* of Liège also staged a good collection of cool Orchids, amongst which we noticed well-grown plants of *Odontoglossum Pescatorei*, *O. pulchellum*, *Oncidium Cavendishii*, *Masdevallia trochilus*, *Cattleya citrina*, and *Lycaste Skinneri*. In the Class 10 for amateurs M. Oscar Lamarque of Liège exhibited well, the most noteworthy being *Cypripedium Parishii*, *Odontoglossum Pescatorei*, an unusually fine variety; *Aërides Fieldingii*, *Vanda Dennisoniana* and some varieties of tricolor; *Lælia superbiens*, and *Huntleya meleagris*. One more collection of Orchids remains to be mentioned; this was some terrestrial kinds shown by M. Louis Van Houtte, comprising *Cypripedium pubescens* and *C. parviflorum*, *Orchis longicornu*, *Cypripedium acaule*, *Orchis maculata*, *Ophrys apifera*, *Aceras anthropophora*, *Ophrys lutea*, *myodes*, and *rosea*, and *Calypogon pulchellus*.

Amongst other plants not noticed in our report of last week were the gold-medal collection of Cape and New Holland plants exhibited by Messrs. W. Rollisson & Sons. The more noteworthy specimens in this collection were small but well-grown examples of *Boronia megastigma*, *B. pinnata*, *B. tetrandra*, *Genetyllis fuchsoides* and *tulipifera*, *Erica Cavendishi*, *Imantophyllum minutum*, *Leucopogon Richii*, *Epacris miniata splendens*, *Toxicophlæa spectabilis*, *Grevillea Preissi*, *Pultenæa rosea*, &c.

NOTES AND GLEANINGS.

LETTERS from various districts, which we were unable to publish last week on account of the detailed report of the Ghent Show, inform us of the severity of the LATE STORM. Expanded blossom exposed to the force of the gale is killed. Rose trees which previously were green and thriving were blackened by the frost wind, and Cabbages were torn in tatters. Such were the tidings that reached us. Still we have strong hopes that the danger incurred by the fruit trees has not been serious; only the Plums as standards had their blossoms expanded, and of these a portion have passed tolerably safely through the ordeal. Pear, Apple, and Cherry blossom, so far as we have seen, is not greatly injured, and trees on walls that were protected by canvas have not suffered to any great extent; but on the contrary, where the trees were exposed to the boisterous wind and drifting snow, the blossom has been so much damaged that good crops of fruit are hopeless. Standard trees cannot well be sheltered, but trees on walls can; and almost every year's experience and losses afford sufficient evidence that early-blossoming wall trees must not only be protected, but the protection must be thorough if good crops of fruit are to be insured. Now that the results of the injury sustained by vegetation owing to the severity of the weather during the last week of March and the first of April can be better seen, and future fruit prospects can in some degree be estimated, we shall be glad to receive information on the subject from cultivators in various districts.

— We are informed that Mr. S. Jennings, the Assistant Secretary, will read a paper at the next Committee Meeting of the Royal Horticultural Society (April 16th), on the GREAT INTERNATIONAL HORTICULTURAL EXHIBITION recently held at Ghent.

— THE spring Exhibition of the TORBAY HORTICULTURAL SOCIETY, held on the 28th of March at the Bath Saloon, was a great success as far as the display itself was concerned, but the wintry weather prevented a large attendance. Those, however, who resolutely braved the cold wind were amply compensated for their pains. On former occasions more than sufficient space was found in the large saloon, but on this occasion it was full to repletion, and the Committee were obliged to occupy the smaller saloon in addition. The six Azaleas staged by Lady Louisa Finch-Hatton, and the three Azaleas and specimens by Col. Campbell, were marked features in this saloon. The larger stands in the centre of the hall were occupied by collections of miscellaneous plants, a magnificent group being staged by Mr. J. Lawless of Exeter, to whom was awarded the premier prize—a silver cup, presented by Mr. C. Richardson of Cary Castle. The nurserymen of the neighbourhood exhibited strongly, and their displays were of more than usual brightness, the favourable season having brought out the blossoms early and freely. The bouquets and table decorations were unusually strong in number, also a lovely basket of cut scarlet Camellias from Mr. E. Vivian grown in the open air, and some good examples of Polyanthus from Mrs. D'Aeth, The Knoll. On the opposite side were arranged some very fine vegetables, and notably two beautiful pans of Mushrooms in a growing state sent by Mrs. Singer of Paignton, also a good dish of ripe Strawberries from the same lady. The nurserymen (Messrs. Curtis, Sanford, & Co.; Messrs. Phillips, Torbay Horticultural Establishment; Mr. W. B. Smale, Horticultural Dépôt) were well represented; indeed, such exhibitions as these could not succeed without their friendly help.

— AT the usual monthly meeting of the HORTICULTURAL CLUB, held on the 3rd inst. at the club house, Messrs. R. Osborn, Fulham; J. Newington, Ticehurst; and Harrison Weir were elected members.

— We have received part 4 of vol. v. of the "JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY," which is much larger and superior to part 3. Besides containing records of meetings the present issue publishes a list of donors of plants and seeds; and furnishes lists of the plants, flowers, and fruits certificated during 1877. It contains also reports on the trials

of Tomatoes, Asters, and Turnips at Chiswick; also papers on the fungoid diseases of the Vine by Dr. M. C. Cooke, and on the Cyclamen by the Editor, Mr. Samuel Jennings, F.L.S., the latter of which, so far as it appears in the Journal, we print in another column.

— MR. WILLIAM PAUL of Waltham Cross sends us the following account of the ORIGIN OF THE GREEN ROSE (*R. indica viridiflora*):—"It was first seen in France in the possession of M. Verdier of Paris, in 1855, who received it from an American nurseryman of Augusta, Georgia. I received it from the late Mr. Mieliez of Lille as a new Rose in 1857." Perhaps American readers can tell us something about the origin and history of this Rose.

— THE following plants were in BLOOM in the open border on the 1st of April at Glenthorne, St. Mary Church, Torquay:—*Anemone fulgens*, *Andromeda*, white *Alyssum*, *Alpine Auricula*, *Borage*, *Cowslip*, *Daisies*, *Heath*, *Hycinths*, *Heartsease*, *Myosotis*, *Oxlip*, *Periwinkle*, *Polyanthus*; yellow and various colours, double white, lilac, and crimson *Primrose*; various *Narcissuses*, *Jonquils*, *Daffodils*, *Pulmonaria*, double white *Stocks*, *Viola cornuta*, white and purple *Violets*, *Tulips*, single and double yellow *Wallflowers*, double-flowering *Almond*, *Berberis aquifolia*, *B. Darwinii*, *Coronilla*, *Laurustinus*, *Ribes sanguineum*, *Apple*, *Pear*, and *Victoria Plum*.

— MESSRS. C. LEE & SON, Royal Vineyard Nursery, Hammersmith, have sent us blooms of the new French VIOLET BELLE DE CHATENAY (Paillet). The flowers are perfectly double, and the petals are well expanded. The colour is white faintly tinged with purplish lilac, especially on the reverse sides of the petals. Every flower exceeds 1 inch in diameter and some are nearly 1½ inch. They are delicately fragrant and very fine.

— IN an article in "Provence du Littoral" on HORTICULTURE AT SAN FRANCISCO in California we read that in the suburbs of that city every house has a small garden between it and the street. These little gardens are generally well kept and furnished with pretty plants, and particularly climbers. In one of them there is a Cloth of Gold Rose which reminds us of *Maréchal Niel*. It is so rambling and vigorous that it completely covers the whole house even to the windows of the third storey; then at this height its branches run on the trellis surmounting a balcony and again hang over in front. The trade in flowers is also very considerable in San Francisco, particularly at La Plaza, which is the part of the city where numerous florists, principally French, are domiciled. Every evening in the streets, at the doors of the theatres, balls, concerts, &c., flower dealers by hundreds sell cut flowers in much greater quantities than they do in New York, Boston, and other large cities of the Union. At San Francisco these cut flowers are chiefly Roses and Tree Carnations, of which a great number of beautiful varieties are cultivated. They also cultivate very extensively forced Roses.

— MR. JARRATT, late in the Orchard department of Mr. B. S. Williams's nursery at Holloway, has been appointed gardener to Robert Warner, Esq., at Broomfield, Chelmsford. Mr. Jarratt will thus have charge of one of the most valuable collections of Orchids in this country, and will have ample scope for turning his training and cultural abilities to good account.

— WE learn with regret of the DEATH OF MR. CHARLES GEORGE TURNER, a youth of much promise, the youngest son of Mr. Turner, Slough. Mr. G. C. Turner selected medicine as his profession, and proceeded to the University of Edinburgh to graduate in the usual way, passed his preliminary examination, and was preparing for his professional examinations, but he has died at the early age of eighteen.

— MR. J. WEBSTER, Gordon Castle, communicates the following hint on HOLLY HEDGES to the "Journal of Forestry."—"If Quick or common Thorn is planted along with Holly, the latter will close up even if planted at the distance of 2 feet apart. The one assists the other to grow up more rapidly, and the Holly will entirely take the place of the Thorn in course of time. Nip the points off the leading shoots of Holly when young, to force strength into the lower branches. There are several of the same sort of hedges about this place."

— A FINSBURY PARK CORRESPONDENT contributes the following testimony to the GROWTH OF LONDON and the invasion of gardens by bricks and mortar:—"Five years ago my cottage was surrounded with fields and here and there a cottage and a garden; the Eel Pie House was in existence,

and the sluice was not demolished. The New River like a silver thread winded round and about. All is vanished. We are a nation of shopkeepers. Where cattle used to graze and rooks were wont to congregate you can now buy tripe and treacle, paraffin oil and pork, second-hand clothes and faggots. We are swallowed up in a wilderness of bricks and mortar."

— MR. W. BIGGS communicates the following description of a FINE SPECIMEN CAMELLIA at Blithwood House, West Derby, the residence of F. J. Babcock, Esq.:—"The tree is growing where it was planted out upwards of sixty years ago, then a large plant, as its history is given with the household. It is now growing on a raised bed 12 by 14 in a large span-roof house 26 by 30 feet, the centre 22 feet high. The Camellia in diameter is 20 feet; girth of stem, 29 inches at 1 foot from the soil; height of tree 19 feet. It is a great bush much cut in to keep it within bounds, and with fine healthy foliage, with a profusion of expanded flowers and buds to open about ten days from this date (March 29th). The quantity of flowers taken off annually for the last ten years is upwards of three hundred dozen. To keep the tree in robust health top-dressings are given annually, and it is also copiously watered with liquid manure from the stable yard and guano alternately, occasionally also with soot water, and it is frequently syringed throughout the growing season. The variety is the old Double White."

— IN the practical notes on growing and forcing SEAKALE contributed to this Journal by "J. P." reference is made to the mode of growing the plants in rows during the summer and digging up every alternate row for forcing, the rows remaining being covered with 6 inches of soil and left to produce late "Kale." We have recently seen some Seakale thus grown by "J. P." and finer produce we never witnessed. The heads were 6 inches in length and as much in circumference, and the sun had done all the heating. Many owners of gardens have the means of growing Seakale, but have neither manure nor other conveniences for forcing it, and hence they deny themselves the luxury of this wholesome and delicious vegetable; but by growing it in the manner referred to, and heaping light soil over the crowns, they will by waiting have produce well worthy of being waited for—that is, if stout crowns are provided. For producing good "Kale" next spring, growing sets should be planted now in ground that has been deeply trenched and enriched with manure.

— THE value of GARDENIAS AS CUT FLOWERS at this season of the year is known by the large prices they are making in Covent Garden Market. Mr. Baker, of Coombe Cottage, has now some excellent plants in the greatest luxuriance and heavily laden with flower buds in various stages of expansion. So profusely are they set that in the space of a square foot we counted over sixty flower buds, some open, others opening for succession. These Gardenias are apparently growing as free as Portugal Laurels, and are huge bushes, the branches measuring several feet from the stem to the points, while the foliage is of the brightest green and remarkably clean. One of the plants is twelve years old, and the flowers on this plant measure $3\frac{1}{2}$ inches in diameter. The plants are in pots plunged in decayed leaves, which we have no doubt the roots have penetrated, and from which they derive a certain amount of nourishment; but the greatest key to success, Mr. Baker tells us, is plenty of water both at the roots and overhead. It is a long time since we have seen Gardenias so profusely set with buds and so remarkably clean and healthy as the admirable examples of culture referred to.

— A BOTANICAL EXCHANGE SOCIETY has been established at Buda-Pesth for the purpose of exchanging specimens of the native plants of Hungary, Transylvania, Croatia, Slavonia, and, as far as possible, of Turkey and Russia, for those of other parts of the world. During the last two years upwards of three hundred botanists have joined the Association, and more than 120,000 specimens have been distributed. All communications and applications for further information should be addressed to Herr Richter Lajos, Erzherzogin Marie Valerie Gasse, No. 1, Buda-Pesth, Hungary, accompanied by a subscription of four marks, or five francs, for which sum an exchange of a hundred specimens will be effected.—(Nature.)

— GARDENERS often experience much trouble in SOFTENING HARD PUTTY, and by such the following plan is worthy of trial. Break the putty into lumps of the size of a hen's egg, add a small portion of linseed oil, and water sufficient to cover the putty; boil this in an iron vessel for about ten minutes, and stir it when hot. The oil will mix with the putty. Then

pour the water off, and the putty will, we are informed, be as soft as if fresh made.

PRUNING TEA ROSES.

IN answer to the query of a lady rosarian as to the pruning of Tea Roses, I am afraid I must plead guilty to giving contradictory advice in two years. The only gratifying part of my fair critic's communication is the proof that my letters are prized by some at least of your readers.

It is true that at the time I wrote practical experience had caused me to believe that hard pruning was good for Tea Roses, nor do I entirely withdraw the opinion now. I still think that for the purpose of producing extraordinary fine blooms you may with advantage prune hard, but with this great disadvantage—you do so at the expense of soon losing your trees altogether. The probability is that the trees will bleed to death, and next season be useless cumberers of the ground.

Since writing the letter to which my fair correspondent alludes I have had considerable experience and also talked the matter over with the greatest amateur rosarian, and I now conform to the opinion expressed by Canon Hole in his book upon Roses, that Tea Roses require the least possible pruning.

For the purpose of convincing your correspondent that my change of opinion is not without good reason I may add that a Tea Rose called Rubens, which is not often of use in an exhibition stand, is growing against a wall in my kitchen garden. It has been left alone for years, and has never been touched with the knife. The tree had been forgotten at the time of pruning, and was not of much value for producing exhibition Roses on account of the petals being so few and loose. This tree last year gave me lovely blooms all the season. I rarely had a large stand which did not contain a good bloom of Rubens. I mentioned this matter to Mr. Baker, and he confirmed my experience by telling me of trees he had of other Teas which had done so well without pruning, that he was quite sure Teas only required their dead wood cutting out and the very slightest of what we may call "tipping."

With regard to the question of Moss Roses, I certainly should not like to pit my poor opinion against such a renowned *magister artium* as Mr. George Paul; and in any conflict of opinion on Rose culture I would advise your fair correspondent to follow his advice in preference to mine.—WYLD SAVAGE.

PHEASANTS AND CROCUSES.

I READ the paragraph under the above heading in your number of the 4th inst., and I would remark a similar case with this exception—that my yellow Crocuses suffer from sparrows instead of from pheasants. Although I grow, probably, thousands of these flowers I never have a clump or patch of them to remain in bloom, for the sparrows pull the flowers from the bulbs as fast as they bloom, but they never touch a Crocus of any other colour, and the mice never have eaten the bulbs of any other colour than those of the yellow Crocus. I have suffered severely from attacks of both kinds during the present year.—MARTON.

HINTS ON LANDSCAPE GARDENING.—No. 3.

VILLA GARDENS.

ATTEMPTS to introduce extraordinary features, or to impart much variety to small gardens, so often end in failure as to induce one again, and yet again, to repeat the warning not to attempt great things with small means. When you do introduce a novel feature especial pains should be taken to render it and its surroundings in harmony with each other. Take for example a pool or little pond of water, for which there is such a general liking. When made in such a conspicuous position as to form the centre and key of the little garden it has such a toy-like incongruous air as to call forth the familiar exclamation, "How very cockneyfied!" Such failures are only too common, yet I have also seen several pools treated with considerable success, and which were really ornamental, simply because they were kept well in proportion to the size of the garden, and were so placed as to present a natural appearance.

It has already been shown how often the desire to secure a certain degree of privacy leads to a hurried indiscriminate planting of tall fast-growing trees, which in the end prove literally a "growing evil." The pun may serve to impress the fact upon the minds of my readers. The site of most small villa gardens is just a bare level expanse, and the owners may

not unreasonably exclaim, "If we do not plant trees how are we to obtain shelter and seclusion?" I reply, By all means plant trees, but do it so as to impart beauty and grace. If such be your aim you will not care to enclose the entire garden with them; there must be a break—openings to which the rounded outlines of the tree clumps pleasantly lead the expectant eye, which there finds that agreeable variety of which it is always in search, presenting itself under the guise of high raised shrub-clad banks formed of the soil excavated to make the pond and to cause the lawn to slope gently down to its margin. By this simple method we obtain a hollow for a pond; we shut in the grounds effectually with the banks, which we clothe

with shrubs and trailing plants, and thus add two or three important features to the garden. It may be that we shall rest content with a pond pure and simple, yet let us not fail to remember that a fountain is quite admissible in such a position, or that many plants which thrive in water are ornamental. Surely everybody caring for flowers must admire our native Water Lily, *Nymphaea alba*; then there is the pretty Cape aquatic *Aponogeton distachyon*, with its narrow leaves and curious white flowers; the yellow *Villarsia*: the Water Violet. *Hottonia palustris*; the stately Lily of the Nile, *Calla aethiopica*, all growing freely in 2 or 3 feet of water. In more shallow depths by the margin we may have Bog Bean, Flowering

Fig. 40.—PLAN FOR VILLA GARDEN.

A, Flower beds; B, Turf; C, Gravel; D, House; E, Spaces for climbers.

Rush, Loosestrife in two or three varieties, and the yellow Water Iris, with Marsh Gentian, Ivy, Campanula, and Musk to enrich the margin itself. There is always so much risk of water plants becoming crowded and overgrown that it is best to plant a few such choice plants as those enumerated than a crowded collection, and even these must be watched and kept within bounds, for they increase and spread with such rapidity as to cover a considerable space in a year or two.

More popular even than fountain or pond are flower beds, and certainly much less difficult to make; yet here, too, failures in the form, position, and number of the beds are very common. Lying beside me upon my desk are two plans of beds in small gardens sent for criticism. One of them (fig. 40) is so elegant that with only a trifling alteration I send it for publication, and would strongly commend it to the notice of everyone having a small front court or enclosure which they wish to make gay with flowers. It is a remarkable example of how much may

be done to render a small square enclosure really ornamental being quite devoid of stiffness or formality, every line being an easy flowing curve pleasant to the sight from every point, and this I regard as perfection in design infinitely more difficult of attainment than the production of fine effect from given points. The flower beds might of course be planted with dwarf flowering shrubs, Roses, and perennial flowers, with spaces for bulbs and annuals, which is much the best style when no means exist for raising a supply of bedding plants. The other plan is an extraordinary combination of squares, diamonds, parallelograms, and rhomboids, admirably adapted for a series of geometrical problems, but unsuitable for the position given them upon turf. I may usefully note here that the best of all forms for a flower bed upon turf is a circle, and if more beds are wanted make more circles. A large bed surrounded by a chain of smaller circles or several large beds in well chosen positions are quite certain to prove more orna-

mental than the most elaborate geometrical design. The plan published is drawn to a scale of one-eighth of an inch to a foot ; but with certain modifications it is adapted to plots of ground having from 20 to 50 feet of frontage.—EDWARD LUCKHURST.

DRACÆNA BAUSEI.

VISITORS to the chief horticultural exhibitions in London and Belgium are well acquainted with the remarkable collection of *Dracenas* raised by Mr. Bause in Mr. Wills' nursery

at Anerley. There are, however, hundreds of gardeners who have not had an opportunity of inspecting those plants, the names of which and the honours they have won are so familiar to all readers of gardening literature.

It will be remembered that some time ago Mr. B. S. Williams purchased the stock of six of the varieties raised by Mr. Bause—namely, *D. Bausei*, *D. Berkeleyi*, *D. Frederici*, *D. Scottiæ*, *D. Renardii*, and *D. Mrs. Bause*. The former of these by the courtesy of Mr. Williams we figure as a typical representative of the celebrated collection. It is selected because it stands

Fig. 41.—*DRACÆNA BAUSEI*.

first on Mr. Williams' list, and because it bears the name of the successful hybridist who was so fortunate in raising the plants referred to.

D. Bausei is not submitted as being the "best of the batch," for in plants possessing such varied points of beauty, and such great dissimilarity in habit of growth and colour, varied estimates must necessarily be formed as to the comparative merits of the several varieties. Some of the "*Anerley Dracenas*" are as far more stately as others are more elegant in habit than the variety figured, while a few may surpass it in richness of colour, but not many, if any, of them possess a greater combination of attractions. In character it is massive yet elegant, and its colours are rich and striking. The plant is comparatively dwarf in habit, with broad arching foliage 4 inches in diameter. The leaves are dark bronze in colour heavily margined with crimson, those in the centre of the plant being further suffused with bright rose. It is altogether a brilliant

plant and cannot fail to prove of great value for various decorative purposes ; but, indeed, all the varieties are valuable for house embellishment, and some of them are eminently suitable for public exhibitions.

ASPARAGUS CULTURE.

I HAVE carefully read over "*A NORTHERN GARDENER'S*" remarks on page 217, and, like many of his previous articles, his notes on Asparagus are entertainingly written ; but however correct his mode of Asparagus culture may be, his inferences as to the result of growing Asparagus in the ordinary way as detailed by me are entirely wrong. Superior Asparagus I have no doubt is cultivated with the rows 3 feet apart, but I hold that Asparagus which could never be rightly termed inferior can be grown, and is grown, in this and many other gardens in beds as I have described.

Your correspondent puts great pressure on having the rows 3 feet apart and 18 inches between the plants to secure and insure vigorous growth; but anyone considering the matter practically will understand at once that planting wide is only a third or fourth-rate power in producing superior results. In Asparagus culture and with all other vegetables I always find that a soil of superior quality will always give similar results let the plants be planted as they will, but in a poor soil wide planting will never make up for a deficiency of nourishment. Asparagus planted 1 foot apart would produce as strong stems as those planted 3 feet provided the soil was rich enough. It is only a question of soil.

"A NORTHERN GARDENER" has omitted to say how many stems are allowed to grow up from each crown or stool. One thing is evident—they will require to be very few, or how is crowding avoided with the stems 8 feet high and the plants only 18 inches apart from each other in the row? This allows each plant only 9 inches to expand on two sides, and yet your correspondent asserts that crowding the stems is the ruination of Asparagus. No doubt "A NORTHERN GARDENER" thinks that by saying that overcrowding Asparagus is as injurious as overcrowding Vines he has made a strong point in favour of his wide planting; but it is a very different thing to crowd Vine shoots and leaves together in a close house where sun and air cannot penetrate to what it is in the case of Asparagus, where every shoot, no matter how close they are growing, bends with the wind and is openly exposed to the sun.

I am not an advocate of, nor do I practise, such wide planting of vegetable crops generally as many recommend, but at the same time sufficient space is given to every crop to develop without producing monstrous or coarse vegetables. I do not assert that superior Asparagus cannot be grown by wide planting, but I must say that disparaging remarks on having the rows 1 foot apart are quite a mistake. As to the recommendation of market Asparagus, I may say that our family do not like it at all, and they have told me repeatedly that the Asparagus they obtain in London is much inferior to what they have here.—A KITCHEN GARDENER.

WEATHER IN ABERDEENSHIRE.

DURING the last days of March and first days of April locomotive traffic of every kind has been interrupted generally throughout the north. On the 1st inst. the general fall of snow had amounted to about 18 inches. The frost has been very severe. On the mornings of 28th and 29th March we had 20°, and since then almost every night it has ranged from 10° to 17°. Apricot blossoms and Pear blossom buds have suffered severely. The leaves of the Bay and Portugal Laurels also seem a good deal affected. Here we have been much troubled with birds scraping and tearing in the south border whenever it was bared by the sun. Threatened starvation seems to have rendered them desperate.—JOHN HARDIE, *Logie Mar, Tairland.*

NOTES FROM MY GARDEN IN 1877.—No. 3.

VEGETABLES.

I HAVE often remarked on the curious fact that although we are here a good deal sheltered, and the soil of my garden is not cold, we are yet much later than other places a few miles more inland. It is to be attributed, I suppose, to the east winds and our lying much exposed to their influence. This year the same backwardness has shown itself, and thus one cannot very well look forward to early crops or boast of having Peas in before the middle of June; but on the whole my garden is, I think, favourable for their growth, but not for monsters. This is a style of gardening I have long since discarded. I do not (in fact never did) see the use of enormous vegetables. Cucumbers a yard long, Celery as big as a gatepost, Broccoli a foot across, have no charms for me. In all such cases flavour and quality are, I believe, sacrificed to size. Unhealthiness is engendered; and as all who have had to do with Potatoes know full well, the larger the Potato the more likely is it to be diseased. So it is in other vegetables, and a moderate-sized one is much more likely to commend itself to the palate than a huge overgrown specimen which figures well on an exhibition table, but not so well on the dinner table.

There has been somewhat of a lull in the production of new Peas. There are indeed so many good ones that it seems well nigh impossible to excel those which we already have. The only new one I had last year, and an excellent Pea it is, was Sutton's Prince Leopold. I depended for my supply on the

following—Ringleader and Sangster's No. 1 for the first crop, Dr. Maclean and Sutton's Improved Princess Royal for second crops, and Sutton's Giant Emerald and Duchess of Edinburgh for later crops. Early Peas were with us a failure, the long-continued cold and dry weather preventing them coming to maturity. The main crops were excellent, but the later were caught by mildew. All these are well-known varieties, but I cannot sufficiently recommend for flavour Giant Emerald. Not that it lacks the other requisites of productiveness and robustness in habit; but as, in my judgment, these are very often obtained at the loss of flavour, which is the first point in a good Pea, we ought to be glad to have so good a Pea where all are combined, and in my garden it has resisted in a remarkable degree the attacks of mildew.

Potatoes, as everyone knows, were a ticklish crop in 1877. I never was so late getting mine into the ground—fully two months later than I have been this year. This did not, however, prevent me from lifting them as usual in August, although many would have said that it was folly to do so in the unripe condition in which they were, but I still preferred that to leaving them to be attacked by disease; and the event justified my doing so. I have not had half a bushel of bad tubers the whole winter. Regents have kept good up to the present time (March 18th); and while my neighbours had to tell of losses, amounting in some cases to one-half of their crop, I have managed to escape. I had not any really new sorts on trial. Magnum Bonum bore out its character of being really an acquisition, and on my chalky soil did well and bore a heavy crop. Flourball, on the other hand, I have been obliged to discard, for the soil does not suit it. As yet I can find nothing to beat Prolific, Snowflake, Lapstone, Yorkshire Hero, and Regent; to these I would add Schoolmaster and Magnum Bonum. My good friend Mr. Radclyffe has sent me this year some Gryffe Castle, which I know to be a good and early Regent, and I have a few new seedlings on trial, but there is great difficulty in excelling those I have already named. As to disease we are as much in the dark as ever about it, at least so far as preventing or curing it is concerned. There are one or two things which seem to me helpful in warding it off, and these are first not to go in for size, for a large Potato seems more liable to disease than a smaller one. Let there be no heavy manuring, and what is done let it be done in the autumn previous. Then the oft-repeated tale, plant early and lift early. And although there is nothing very scientific in these directions, yet where they are adhered to I believe there will be as little of it as can well be.

In Cucumbers there has been nothing remarkable amongst new varieties; but there is one which Mr. B. S. Williams sends out—Woolley's Telegraph, which is one of the very best and most prolific that I know and suits admirably for a frame, a point in which many otherwise valuable sorts fail. Those of us who cannot afford houses have been oftentimes disappointed in growing varieties which at first promised well, but afterwards, owing to their requiring more constant and regular heat, have done nothing; and then, when it is too late and the crop gone for another year, the mistake is found out; but this is most hardy, and bears a heavy crop of good-sized Cucumbers, and with Duke of Connaught (white spine) a good supply is sure.

I have been disappointed in Witloof as a salad plant. With me it was not at all equal to the Barbe de Capucin which I used to obtain from Vilmorin's, nor did it give so large a supply of salading. I have not tried it as a substitute for Sea-kale, being quite satisfied with my supply of that vegetable.

In Broccolis the only noticeable sort which I have not grown before was Sutton's Late Queen. It deserves its name, for it is the latest of all, heads being available up to the middle of June. It is, moreover, dwarf in habit and the heads are well protected. When seeds of Broccoli can be obtained true to name there is a chance of getting a supply all through the winter and spring months; but that is the difficulty, and all kinds seem to get mixed together in hopeless confusion.

I have frequently told of the impossibility of growing Tomatoes in our neighbourhood owing to the attacks of disease. Last year I succeeded somewhat better, but it was simply by picking them the very moment there was the least appearance of colour and then allowing them to ripen indoors, for the disease again made its appearance and any that were left on rotted. I have seen in the orchard house of a friend lately Tomatoes planted out in the border, trained on a trellis, and bearing a succession of fruit from June last up to the present time. They are now making a fresh start, and will continue

to bear until the plants of the year are strong enough to produce fruit. I have not seen them grown in this way before, but as the same mode is adopted with Cucumbers there is no reason why it should not answer elsewhere as it has done in this instance.

Such are the few facts which in my last year's experience have seemed noticeable. That they are not more numerous may in one sense be an advantage, as an indication that the rush of novelties is not quite so strong as it was, and that some of the older sorts of vegetables are reasserting their place from which they had been ousted by their newer rivals.—D., *Deal*.

ON THE CYCLAMEN.

[By S. JENNINGS, F.L.S., &c. Read at the Royal Horticultural Society's Meeting, 19th February, 1878.]

TWO of the hardy species, *Cyclamen Coum* and *hederæfolium*, are mentioned as having been in cultivation in Gerard's garden so long ago as 1596, so at least says Mr. Daydon Jackson in his identification of Gerard's species. *C. persicum* seems to have been introduced by Sibthorp in 1731 from the Isle of Cyprus. In "Curtis's Botanical Magazine," which was commenced in 1790, the fourth plate in the first volume is a very fair representation of *C. Coum*, which is said to be found growing in woods and shady places in Italy and Germany; it is also noted that it is a very early flowerer. The plate in Curtis represents a tiny little plant with small rosy flowers on rosy peduncles, leaves round and unvariegated. The original *C. persicum*, though more beautiful with its pure delicate petals and graceful habit, is a long way behind the magnificent specimens we have so often seen in recent years, to which I shall allude presently.

As a genus the *Cyclamen* is confined to the countries bordering on the Mediterranean—S. Europe, W. Asia, and N. Africa. It can scarcely be considered an English plant, though it may be found growing wild in some Kentish woods. It is almost certainly naturalised, the seed having been originally carried from some garden, and thus it has established itself as in a state of nature. The *Cyclamen* is a very worthy member of the natural order Primulaceæ, which contains so many popular favourites. Amongst other distinctions the chief points of note in examining flowers belonging to this order are:—1st, That the corolla is invariably monopetalous—that is, the petals are all united together in one piece as a tube, the extremity of which is, however, usually divided into several lobes or segments, usually five in number, so that in speaking of the petals of a *Cyclamen* we mean the separate segments of the united corolla; and 2nd, That the stamens are inserted upon the corolla, and opposite to the several lobes. There is also the capsuled many-seeded fruit. In the genus *Cyclamen* the segments of the corolla are always reflexed or doubled back, and sometimes twisted.

There appears to be no little confusion in the determination of some of the species, as there unquestionably is a misapprehension amongst the trade both here and abroad on the subject of nomenclature; even our best authorities differ. It is most desirable, therefore, that a general understanding be arrived at, if possible, whereby it shall be recognised what really are the points of difference between the various species. With the kind aid of several well-known *Cyclamen* growers I have made an attempt in this direction, which may perhaps be of some use until a better arrangement can be supplied. Here at starting a serious difficulty meets us, Upon what are we to base our distinctions so that no mistake can occur, so that when a plant is shown it may be possible to say definitely this is *hederæfolium*, or *ibericum*, or *vernum*, as the case may be? The leaves furnish one of the main distinctions, but only in conjunction with other features. Many authorities lay great stress upon the colour of the upper and under surfaces, but this is fallacious; and not much less so with the form of the leaf. Take *hederæfolium* for example: you have ovate, cordate, hastate, and sub-hastate leaves, and all may be produced from the seed of a single plant. Leaves may therefore assist in identification, but cannot alone determine it. We must look to other points to assist us in our task.

The corm is a very important feature, and one which deserves consideration—its shape, its habit, the mode of issue of the fibre, a careful examination of which will probably throw valuable light on this vexed question, for if we consult the authorities we shall most certainly be led astray in many instances; for example, in the "Bot. Mag.," plate 1001, is figured a plant under the name of *C. hederæfolium*, which on

examination proves to be *vernum*. The same plant is figured in Sweet's "Fl. Garden" as *repandum*, pl. 117; and again the same writer, pl. 9, figures *C. ibericum*, but calls it *vernum*; and later writers, copying from the earlier ones, have only perpetuated these errors. In all, though many more names have been given, for all practical purposes the number of species of *Cyclamen* may be reduced to six—viz., *C. Coum*; *C. ibericum*, incl. *C. Atkinsi*; *C. vernum*, syn. *repandum*; *C. europæum*; *C. hederæfolium*, with its geographical forms—*C. africanum* or *macrophyllum*, and *C. græcum* or *latifolium*; *C. persicum*. There may be, I should say there are, other little-known species to which at present I have not had access.

There is another point of distinction worthy of note, illustrating as it does the fact that every season has its *Cyclamen*. *Persicum* and *vernum* cheer us in the spring with their bright vivid flowers. *Europæum* comes on later, and may well be distinguished as the summer-flowering species. In the autumn we have *hederæfolium*; and when that is done, all through the winter the chain is completed by the little *Coum* and *ibericum*, which are then in full bloom. This is a very marked distinction, by the aid of which closely resembling individuals may perhaps be determined with certainty.

There seem to be four distinct habits of the corms or tubers, as follows:—Corms smooth, roots proceeding from the centre of the under surface—*Coum*, *ibericum*, *vernum*. Corms rough, roots proceeding from the base of the tuber, but more or less from all parts—*europæum*. Corms large, rough, fibrous, roots proceeding from all parts of the tuber—*persicum*, *hederæfolium*. There is a form of *hederæfolium* with a very distinct habit of tuber. The roots proceed from one part of the under surface, a little removed from the centre of the corm, whilst the growing point on the upper surface starts from a corresponding point on the opposite side of the centre, and this peculiarity is said to be constant. I have examined specimens, but my personal knowledge of this variety is not yet sufficient to enable me to do more than allude to it at present.

We now come to the leaves, of which there are four main variations in form and habit:—I.—Round or reniform. Not marbled—*Coum*. Marbled on upper surface—*ibericum*. Sometimes inclined to be cordate—*europæum*. II.—Cordate, crenulated on margin, upper surface marbled—*persicum*. III.—Angular, toothed, broadly marbled on upper surface, leaves rising with the flowers—*vernum*. IV.—Angular, lobed, marbled, leaves succeeding the flowers—*hederæfolium*.

Finally, as a less reliable guide, we have fragrance, but here there does not seem to be any unchangeable or distinct habit. *Europæum*, *vernum*, and *persicum* are said to be always fragrant. So they are in nature, but in cultivation this very desirable quality is in great measure lost, and in the large otherwise improved *persicums* entirely so. *C. Coum*, *ibericum*, and *hederæfolium* are always scentless, except the two forms of the last—*africanum* and *græcum*, which are sometimes fragrant.

We will now proceed to a closer examination of the six species I have named.

I. *C. COUM*.—A native of Italy and Germany. Blooms from January to March. Colour bright rosy-red, with a white band more or less distinct round the corona. Leaves always round, dark green on the upper surface, decided purple on the reverse. No markings. Tubers round, compressed, smooth, roots descending from the centre of the under side. It is very hardy, and flowers freely in the open air. There is but very little variation in this species, which can be easily recognised, for no other *Cyclamen* has its small plain round leaf or short little flower.

II. *C. IBERICUM*.—A very near relation to the foregoing, so near indeed that but for the difference in the leaf it might easily be mistaken. I have a white variety of *C. Coum* in which the plant is unquestionably *Coum*, but the flower is just as certainly *C. Atkinsi*, a white variety of *ibericum* to which I shall recur. Leaves cordate, they are seldom round, always marbled with lighter colour on the upper surface. The tuber is similar in habit to *C. Coum*, but the whole plant—corm, leaves, and flowers—is bolder in habit.

Mr. Atkins of Painswick, a gentleman who has spent many years of his long life in horticultural pursuits, raised a very beautiful variety of this species with pure white flowers, which some have said to be a hybrid between *C. Coum* and *C. persicum*. This is not impossible, though there is a strong belief that the plant known as *Cyclamen Atkinsi* is no more than a white seedling of *ibericum*. The flowers are certainly finer in form than either *C. Coum* or *ibericum*, a feature which

doubtless gives weight to the opinion that it is a hybrid; but when it is remembered how great has been the improvement effected in *C. persicum* during the last few years through careful selection and cultivation, it need scarcely be a matter of surprise that the other species respond to like care and develop into much finer forms than any we have yet seen, of which, with due deference, I believe *C. Atkinsi* to be an example, and not less an encouragement to cultivators to direct their attention to these useful and hardy plants. I give both opinions on this subject, and though I incline to the latter I desire to give the former due prominence. In some catalogues there are named varieties of *C. Atkinsi*—as, for example, *rubrum*, *roseum*, &c.—but it is certain that the founder of the variety will not admit them to be *C. Atkinsi* at all. Mr. Tyerman says that a very interesting series of Iberian specimens of *C. ibericum* have lately been added to the Royal Herbarium at Kew, which quite confirm the identity and variableness of this plant.

(To be continued.)

NORTHERN SPY APPLE—GLADIOLUSES.

IN reply to "A COUNTRY PARSON'S" inquiry allow me to state that I had a Northern Spy Apple tree which did not bear, consequently I moved it in the autumn of 1875. The following summer it had rather a struggle for existence, but the moving had the desired effect, for it produced a fair crop last year and is showing well for bloom this year. If "COUNTRY PARSON'S" trees are not large I would recommend him to replant them next autumn; if too large, open a trench on one side and prune the roots in October. The fruit last season was fine and useful for cooking, but it was not a good season for judging dessert fruit, so I cannot speak as to that.

I am sorry "D., Deal," has had such bad luck with his Gladioluses, but the last two or three seasons have not been very favourable for them. I am not a Gladiolus grower, but used formerly to have a few good flowers; lately, however, they have been miserable failures. With regard to the disease, I think it arises from some defect in the constitution of the plant. They want weather made on purpose for them. If as much attention had been paid to their hardiness as to the beauty of the flower there would not be so many complaints. Perhaps if "D., Deal," were to go back to some of the older varieties he might be more successful, but I would plant them in a fresh situation.—AMATEUR, Cirencester.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE ordinary monthly meeting was held on the 2nd inst. in the Hall, 5, St. Andrew's Square. There was a large attendance of members. The President in the chair. Twenty new members were enrolled. In commencing the second year the Chairman in some introductory remarks reviewed the work the Association had done in the first year of its existence. Founded on sound principles, and managed in a quiet way, it had reached a stability which the most sanguine of its members could not have predicted twelve months ago. In its endeavour to disseminate gardening information it had been largely aided by the horticultural press. The second session was being entered upon under encouraging circumstances with a rapidly increasing membership. The Chairman also dwelt upon the great benefits to be derived by the younger members from such an Association, and concluded by referring to the great stimulus given to horticulture by the leading gardeners a quarter of a century ago, when Chiswick attracted so much attention.

Mr. McAdam (son of Dr. McAdam, lecturer on chemistry), gave a very instructive lecture on the food of plants. He went into the various phenomena of vegetable life, described them in detail, and showed how the properties came to be extracted from the soil. With this process going on the earth became exhausted of those substances that support vegetable life, so that human ingenuity and common sense were brought to bear on the question how nutritive matter taken from the soil was to be returned. This question is answered by the restoring of decayed animal substances and mineral matters to the soil—in fact, that in order to keep up a system of fertility there was required a constant restoring of nature. These restoratives take the form of coprolites, the fossil remains of bones, muriate of potash, common salt, sulphate of magnesia, sulphuric acid, &c. Mr. McAdam mentioned the uses of these matters, defined their properties, and showed samples of the different kinds of artificial manures. He concluded his able paper by promising to pursue the subject further on another occasion. Mr. McAdam received a hearty vote of thanks for his lecture. Mr. Hugh Fraser then in a short paper described the *Boronia megastigma*. Mr. James Spiers, Haddington, exhibited an *Auricula*, and Mr. George McClure a *Cineraria* flower. The

report of last year with syllabus for present session was put into the hands of members. A letter was received from Mr. John Webster, Gordon Castle Gardens, saying that he would be glad to send some "Remarks upon Peach Culture in the Open Air in Scotland," to be read at a future meeting.—ALEX. MILNE, Assistant Secretary.

WORK FOR THE WEEK.

KITCHEN GARDEN.

FOR affording a supply of Peas in August sow now Veitch's Perfection, Dr. Maclean, and Maclean's Wonderful, which combine quantity with quality, and are from their sturdy habit and moderate height, more suitable for exposed situations than tall varieties. Of late varieties Maclean's Premier and Omega are of moderate height, and are superior alike in cropping and quality. Ne Plus Ultra is one of the best late Peas. If sown at the same time as Peas of the Veitch's Perfection type it will succeed them. Another sowing of Longpod and Windsor Broad Beans also should be made. A sowing of Lettuce should be made every fortnight or three weeks, so as to maintain a succession. We sow in drills 15 inches apart, and thin the plants to 12 inches apart, choosing an open situation and rich firm soil. By this plan the plants are less liable to run to seed than when they are transplanted, and much labour in watering, &c., is also saved. Neapolitan is the best Cabbage Lettuce for summer, and the best Cos variety is the Alexandra White. Stanstead Park Cabbage Lettuce and All the Year Round are now furnishing good heads, to succeed which look over the Cos varieties, and tie up the earliest when the plants are dry. Broccoli should be gone over frequently in frosty weather, breaking the leaves over the heads of such as are coming into use. In southern and warm localities a sowing of Kidney Beans may be made on a warm south border. We sow a row 1 foot from the base of a south wall, which gives earlier produce than those sown across the border, the protection given the fruit trees protecting also the Beans. Osborn's Forcing is the best for sowing in front of the wall; it is good also for the open, as is Williams's Prolific, Negro Longpodded, and the fine variety Canadian Wonder. The very early Celery, if it has been grown-on in gentle heat near the glass and duly attended to, will be shortly ready for planting, and should have air rather freely; but avoid chilling the plants too much, as that will give them a check, causing them to "bolt." To receive them the soil should be taken out a little less than the size of handlights and 1 foot deep, placing 6 inches of thoroughly decomposed manure in the bottom, and 3 inches of soil over it to plant in. Four plants may be planted equidistant under each handlight, keeping them rather close until established, then admit air more freely, yet keeping the glasses on, and closing at night until genial weather ensues.

Forcing Department.—Sow seeds of Vegetable Marrows in gentle heat; when the second leaves appear pot the plants off singly, and grow them on, having them strong and well hardened off for planting out under handlights in May. Long White is the best for general purposes, Custard and Moore's Vegetable Cream being prolific and of superior quality. Attend to the thinning of successional crops of Carrots, &c., in frames, watering and giving air freely according to the weather. Lettuces in frames sown early for planting out should be planted forthwith, they having been well hardened off, but they will come in much earlier if undisturbed; indeed, Early Paris Market is commencing to heart already. Potatoes before being earthed should have a good watering with liquid manure; those having tubers of an useable size are best kept rather dry for a few days before they are taken up. Pot off and shift into larger pots Tomatoes as they require it, keeping them near the glass so as to have them short-jointed. Those in the fruiting pots will require attention in stopping and tying; keep the plants to one stem, removing all laterals as they appear, stopping the leader when four or five trusses of bloom are formed, and when the fruit is fairly set giving the plants liquid manure twice a week. Earth-up Cauliflowers under handlights, and water them with liquid manure.

MUSHROOMS.

After the middle of May Mushrooms do not succeed well in a Mushroom house, they being liable to be maggoty. Beds may be made in an open shed with a north aspect, but such beds produce Mushrooms inferior in quality to those borne by beds in the open air. A dry situation should be chosen for the beds, and elevated so that water after rains will pass away freely. Shake out the droppings from fresh stable litter, removing the coarser strawy parts of the litter, retaining sufficient of the shorter material to bind the whole into a solid mass. Place the long litter, or a portion of it, at the base, and make the beds somewhat loosely, and when fermentation takes place make the manure solid by treading and beating. When the heat declines to 90° in the interior of the bed, or 75° at the depth the spawn is to be placed, the bed should be spawned, inserting pieces not less than an inch square and 9 inches apart, covering them 2 inches deep and beating firmly after insertion. Cover the beds with a thin layer of fine straw or coarse hay, and in about ten days' time double it. In twelve to fifteen days after spawning examine the bed to see if the spawn

has commenced "running;" if it has, place a covering 2 inches in thickness of good turfy loam on the bed, and beat it firm. If the soil is not sufficiently moist for binding water it well, so that it may be made smooth with the back of the spade, covering it with the litter as before. In about six weeks the Mushrooms will be showing, and will require attention in watering if the surface of the beds is dry, removing at the same time any portion of the covering material that has decayed, replacing with fresh. Straw is preferable to hay for placing on the beds, as it more effectually throws off the wet. We find a light wooden framework covered with frigi domo very serviceable during rains, and with such protection only a very slight covering of hay or litter is required.

HARDY FRUIT GARDEN.

March came in like a lamb and went out like a lion. Frost followed by snow set in on the 24th of the month, and continued more or less during the last week. During the night of the 30th the temperature fell to 19°, or 18° of frost, and at 10 P.M. on the 31st it fell to 16° at 4 feet from the ground, snow having fallen from 10.30 A.M. to 8 P.M. Our canvas coverings had not been withdrawn, so that they were coated with the snow, which gave us hope of safety for the Apricot and Peach blossom, the former being fully expanded and the latter just bursting. Upon lifting the canvas recently we were gratified to find that no injury had been done by the frost, and so far as we can see the Pear and Plum blossom is unhurt. Gooseberries appear none the worse, thanks to the snow, there fortunately being no wind to displace it. The snow afforded a valuable covering to orchard houses and unheated Peach houses, as it kept the temperature from falling lower than 80°, and no apparent injury has been done to the blossom, which promises to set freely.

FLOWER GARDEN.

Hardy annuals for the principal summer display should now be sown. They are indispensable for borders, but often have a "weedy" appearance from being sown too thickly and neglected in thinning. In heavy soil it is preferable to place about an inch thickness of fine soil where the patches are intended to be, and in this sow the seed, covering it lightly. No garden should be without *Alyssum maritimum*, *Calliopes*, *Candytufts*, *Centaurea Cyanus*, *Centranthus*, *Chrysanthemum coronatum* and *Dunnett* vars., *Clarkias*, *Collinsias*, *Echscholtzias*, *Godetias* (especially *Lady Albemarle*), *Larkspurs*, *Leptosiphons*, *Linum coccineum grandiflorum*, *Lupins*, *Nasturtiums*, *Nemophilas*, *Silenes*, *Senecio elegans* var., *Viscaria*, *Virginian Stock*, and *Whitlavia*. *Mignonette* should be sown in quantity. Rose borders and beds always attract visitors. The ground between the Roses should be sown with *Mignonette*, which will come into flower when the Roses are going off; indeed, patches of *Mignonette* should always be distributed in borders adjoining walks frequented by ladies in the evening. Night-scented Stock (*Mathiola bicornis*) and other plants with sweet-scented flowers or foliage are suitable for similar positions. Half-hardy annuals, such as *Asters*, *Ten-week Stocks*, *Phlox Drummondii*, *Ageratum*, *Clintonias*, *French and African Marigolds*, *Palava flexuosa*, *Portulacacas*, *Salpiglossis*, *Scabious* (double), *Schizanthuses*, *Zinnias*, and *Helichrysums* may be sown in frames either with or without heat. A warm situation should be chosen. Fermenting manure may be placed in the frame to within 8 inches of the glass and be covered with 8 inches of loam. The seed should be sown thinly in drills 2 inches apart, keeping the lights close until the seedlings appear, when air should be admitted moderately. In case hot dung is not at hand a few inches of soil may be placed in the frame, the seed sown, the lights put on and kept close, and sturdy plants may be raised. The seedlings are pricked off into cold frames when the second leaves are fairly formed, keeping the plants rather close and shaded until established. Very much better plants are had in this way than those coddled in heat. *Alströmarias* are fine for cutting; seed should be sown where the plants are to remain.

Plant double *Pyrethrums*; their flowers are little inferior to *Asters*, and come in when showy flowers are scarce. A few select varieties are *Ne Plus Ultra*, *Delicatissimum*, *Galopin*, *Striatum plenum*, *Princess de Metternich*, *Boule de Neige*, *Carminatum plenum*, *Impératrice Charlotte*, *Progress*, *Roseum Perfectum*, *Brilliant*, and *Gloire de Stalle*. *Pentstemons* are very showy, and should be grown in every garden. They are very useful for cutting. *Hollyhocks*, if fine spikes are wanted, must be planted at once; also *Gladioli*, though a few may be planted at intervals up to May to afford a succession of blooms. *Violets* in frames, after the plants are well hardened off, to be taken up, have the soil shaken from them and be divided, preserving only rooted suckers and runners for planting out in an open situation in rich soil. The old crowns may be retained if there is a deficiency of stock, removing all offsets and shortening the root stems. The plants should be planted 1 foot apart every way, but small growers such as *King* may be planted 9 inches apart. The best *Violets* in singles are *Victoria Regina* and *White Caesar*; in doubles, *New York*, *De Parme*, and *Queen*. The plants must be well watered; all weeds and runners must be removed as they appear. Plantations for the open ground may be made as the plants go out of bloom. Ivy against buildings, &c., should be clipped. It ought to be done annually, or at most every other year, if only for

neatness and for imparting a trim and fresh appearance. Proceed with the pruning and planting of evergreen trees and shrubs. Prune Roses for late bloom. Complete the planting of *Violas* and *Pansies*, so as to have them well established before dry hot weather sets in. Continue the planting of hardy edging plants, and if the groundwork, &c., be complete *Dell's Beet*, *Chilian Beet*, *Perilla*, *Saponaria*, and *Golden Pyrethrum* may be sown where the plants are to remain. *Alternantheras*, *Iresines*, *Colusesas*, and *Mesembryanthemum cordifolium variegatum* may yet be propagated, and if there is a scarcity of stock of any other bedding plants their propagation must be proceeded with at once. Prick-out or pot-off such plants as require it, but avoid coddling, bringing them up hardy, not aiming so much at size as a well-branched sturdy habit. Plants which are employed for ornamenting baskets, trellises, rooteries, &c., in summer should now have attention, potting-off and growing-on cuttings or inserting them, and sowing seeds in gentle heat of *Tropaeolums*, *Cobaea scandens*, *Maurandya*, *Convolvulus major*, &c. *Calceolarias*, *Verbenas*, *Lobelias*, and other bedding plants of comparative hardiness may be planted-out in turf or sunk pits where they can be protected with mats, &c., in frosty weather.

FRUIT HOUSES.

Pines.—The suckers or plants which were disrooted and started early in March will now require attention. The pots require to be full of roots, but before the plants are root-bound shift them as advised in a former calendar, watering them a day or two previously so as to have the balls moderately moist when the plants are potted. They may be shifted into 9 or 11-inch pots according to the kind. Take advantage of the removal of the plants to examine the state of the bed, replenishing it if needed by the addition of fresh tan, mixing it with the old to a depth that will afford the temperature required—viz., 95° at the base of the pots until the roots reach the sides of the pots, when 90° is more suitable, especially to fruiting plants, which should now have the atmosphere well charged with moisture, syringing the plants overhead at closing except those in bloom. Ventilate at 80° a little, freely at 90°, and close the house at 85° from sun heat, using no more artificial heat than is necessary to maintain a night temperature of 75° to 70°, 5° lower in cold weather in the morning. Look over the plants twice a week, water those that require it.

Figs.—No other fruit tree produces surface roots so abundantly as the *Fig*, if measures be taken to encourage them by means of a mulch 3 or 4 inches thick of partially decayed manure given when the trees are fairly in growth. This if kept in a moist state will be full of active feeders by the time the trees need the most assistance in order to perfect the crop. Those trees that were started early and swelling-off the fruit should have a good watering with liquid manure. This is more particularly applicable to trees in pots, which require mulching or reversed turves placed upon the surface of the pots to encourage surface roots and increase the number of feeders for the absorbing of the stimulants applied in liquid form. Small kinds such as *Early Prolific* and *Early Violet* will soon be showing signs of ripening, upon which syringing must cease and a lessened supply of water given, or the fruit will be insipid, but keep those swelling the fruit well supplied with water until ripening commences. Temperature 65° to 80° at night, 70° to 75° by fire heat, 85° from sun by day, admitting air at 75°, closing at 80°. Attend to tying-in the shoots in succession houses loosely to allow for their swelling, and mulch the borders if not already done in successional houses.

Cherry House.—Syringe the trees twice a day, keeping the surface of the border moist, and not the surface only, for the border must have a good soaking of water, and in the case of a heavy crop and the trees not in a vigorous condition liquid manure should be applied. Ventilate very freely, commencing at 50° the minimum day temperature, maximum 65° from sun heat unless it rise higher with full ventilation, 45° to 40° by artificial means at night. When the shoots have made four or five leaves or joints pinch-out the point of those that are to form spurs, the terminals train-in without stopping, as also those which are required for furnishing the trees. Black fly must be destroyed by repeated fumigations; it is not so easily eradicated as green or brown aphids.

Strawberries in Pots.—The weather has been very unfavourable lately for plants in flower, which are liable to get chilled by an influx of cold air playing directly on the flowers, as is the case with plants on a level with the ventilators. It is well when the ventilators are above the plants or beneath the pots; in such position we have the *Strawberries* doing well, whilst those on a level with the ventilators are doing as indifferently. In dull and cold weather it is well to shake the flowers occasionally when the pollen is ripe, especially after a "blink" of sun, and where fine fruit is wanted it is desirable to thin the flowers, leaving from eight to a dozen upon a plant, and making choice of the boldest for retention, which are usually the first to expand, the centre fruit of the truss being usually the largest and not unfrequently cockscomb-shaped. It is also advisable to thin the fruit after they are fairly on the swell. We find that if we have a dozen or more fruit to a plant that about a third are fairly good fruit and

the others small, the total weight being no more than when the fruits are thinned to half a dozen. Fruit of 1 oz. weight should be aimed at, the larger the better. We have not exceeded 2 ozs. weight from pots, and only once had twelve fruit weighing a pound before June.

PLANT HOUSES.

Greenhouse.—Petunias now in small pots shift into larger, using a compost of good loam enriched with a little decayed dung and leaf soil, stopping the shoots to induce a branching habit. They are very useful after Pelargoniums are over, and continue until late in the season. Abutilon Boule de Neige is very useful and ever blooming. Cuttings of the growing parts strike readily in sandy loam in gentle heat, and if potted-off and grown-on in a light airy situation they will bloom freely when a few inches high. Bouvardias when rooted should be potted-off and grown-on in a moist atmosphere in an intermediate house, keeping them near the glass, shifting into larger pots as required, avoiding the extremes of cramping the roots or of overpotting. Cyclamen seedlings when they can well be handled should be carefully lifted and placed about 2 inches apart in pans, and be grown-on in a moist warm atmosphere. When they have formed three or four leaves pot them singly, keeping them in heat near the glass and slightly shaded. Old plants after flowering should be kept in a light airy position and be duly supplied with water until the close of May, when they may be planted outdoors or be stood on ashes in a cold frame. Cineraria seed for early bloom should be sown without delay. Earlier seedlings should be kept near the glass so as to keep the plants sturdy. They must not be crowded in the seed pan, but must be pricked off as they require it. Primula seed for the principal winter display should now be sown in gentle heat, also Balsams, which are fine summer ornaments. Other tender annuals should now be sown, not omitting Cockscombs and Celosias. Kalosantes will be advancing for bloom and must have due supplies of water, or they will cast the lower leaves and become unsightly. Plants of Solanum capsicastrum and Pseudo-Capsicum should now be cut-in closely, turned out of the pots, the balls reduced two-thirds and returned to the same size of pot, assigning them a light airy position. Syringe them overhead, but water the roots carefully. After May they may be placed outdoors in a sunny situation, or what is preferable, be planted out. Cuttings may be inserted; they strike readily in gentle heat, and should when rooted be potted off and planted outdoors in June. These with the old plants should be lifted in autumn and potted. Insert cuttings of Salvia splendens in loam and sand. Cuttings not over-strong are best. Place them in gentle heat, and keep them moist and shaded. Pot off when rooted, and grow-on in a cold pit. S. gessneriflora and S. Heerii are also good for flowering in winter. Hydrangea cuttings strike readily now. Select the young growing parts from the base of the plants, inserting them in small pots and placing them in moderate heat. H. hortensis, H. Thomas Hogg, and H. stellata flore-pleno are fine, the last doing well in small pots. Seed of Campanula pyramidalis may now be sown in gentle heat, and the plants being grown-on through the summer fine specimens may be had for next season's flowering. Lilliums advancing for flowering assist with weak liquid manure, affording them plenty of light. Plants in flower should be shaded from bright sun to preserve their colour and prolong their durability. Admit air freely, avoiding cold draughts, employing fire heat only to exclude frost.

TRADE CATALOGUES RECEIVED.

James Veitch & Co., Royal Exotic Nursery, King's Road, Chelsea, London.—*Illustrated Catalogue of New Plants and List of Soft-wooded and Bedding Plants.*

B. S. Williams, Victoria and Paradise Nurseries, Holloway, London.—*Illustrated Catalogue of New Plants.*

J. Linden, 52, Rue de Chaume, Brussels.—*Catalogue of New and Ornamental Plants.*

Rawlings Brothers, Old Church, Romford, Essex.—*Descriptive List of Dahlias.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (A Constant Reader).—We cannot tell the prices. Apply to your bookseller.

GRAPES DISEASED (W. M.).—They are severely attacked by spot. Thin the bunches and mulch and water the roots copiously with tepid water. Keep also the atmosphere sweet by early and careful ventilation, guarding especially against confined moisture.

GLOIRE DE DIJON ROSE IN POTS (H. G.).—We do not quite understand your question. Gloire de Dijon is so prolific as to surpass most other varieties in the quantity and size of the flowers, which it invariably produces both in and out of pots. We are unable to answer your question in reference to the Birmingham Rose Show.

DOUBLE CYCLAMEN (Sir Henry S. S. Bart.).—The flower you have sent us as having been "raised by Mrs. Hurst, wife of the gardener at Thorpe Constantine, Tamworth," is very good. The flower is large and compact, and contains eleven well-formed petals. The colour is also attractive—rose suffused with violet.

RAPHIOLEPIS OVATA (Mrs. C. M.).—The above is the name of the shrub of which you have sent us a spray. It is commonly called the Indian Hawthorn, and was introduced from China. It is propagated by cuttings selected when the wood is half ripe, and inserted in sandy soil under a hand-lit in a shaded place.

DAHLIAS (Romford).—Apply to your neighbours, Messrs. Rawlings, Old Church. They have a large collection varying in price from 4s. 6d. per doz. to 10s. 6d. per dozen.

AZALEAS UNHEALTHY (S. M. C.).—One great cause of the unsatisfactory condition of your plants is, judging from the sprays sent, immature growth. The shoots you have sent us were made late in the season and in a shaded place, and from growths made under such circumstances neither healthy foliage nor good flowers can be expected. Shorten all the diseased shoots at once, cutting them back to sound wood. Place the plants in heat and syringe them frequently, and if the roots are in a healthy state fresh growth will ensue. The plants must remain in a moist genial place until June or July, and must then be gradually inured to endure all the sun and air possible to ripen their wood. If you have not a light unshaded house for them, place them out of doors during August and September, or until the autumn rains occur. They require free drainage, firm peaty soil, and copious supplies of water.

RAISING NEW ZEALAND PLANTS FROM SEED (De Bosco).—Select suitable pots or pans, put in plenty of drainage, fill to within an inch of the rim with fine rich gritty soil, water, sow the seed, cover with a thin layer of soil, which press gently upon the seed, and place the pots in a vinery or garden frame upon a hotbed with a temperature of 60° to 70°. Shade till the seed vegetates, and then gradually expose the seedlings to the full light. Pot singly in 4-inch pots as soon as the plants can be handled, keeping them in heat till the roots are in full activity, then remove to a greenhouse and repeat as the growth makes progress. Raise a few plants from cuttings when such can be had. Treat the whole of the plants as hardwooded greenhouse plants, and next season, if you reside in the southern counties, try a few plants planted-out in various positions in the open air. We have seen Pittosporum undulatum established in the open air in Cornwall forming large handsome shrubs. Acacias and Eucalypti may also be met with in a flourishing condition and of considerable size in the gardens of that county. We have several Eucalyptus globulus established in a garden south of London, and we also have Eugenia Ugni and several Myrtuses growing well trained to an open wall; but we fully expect to lose the Eucalypti in the first hard winter. We state this to show you that planting in the open air should be regarded as an experiment doubtful in its results, and therefore not desirable for all the plants of any kind.

HOLLY LEAVES INJURED (An Old Subscriber).—The discolouring of the leaves is caused by the grubs hatched from the eggs of a very small fly having but two wings, named Phytomyia ilicis. We know of no remedy.

REMOVING THE BARK OF A TREE (J. R. B.).—If the bark is removed from a tree all round its stem that tree will die.

FLOWER BED ARRANGEMENTS (Subscriber).—For an exposed situation the best blue bedding plant is Viola Tory, and for a bright scarlet Nasturtium King of Tom Thumb, or, if you require a rich shade, Nasturtium King Theodore, deep crimson. Take especial care that the Nasturtiums are not planted in rich soil, or you will have a rank growth of foliage at the expense of blossom. Planted in soil of medium strength they bear flowers abundantly, and make bright masses of colour. If the soil and situation are such that Pansies do not flower continuously you might substitute a purple for a blue and plant Purple King Verbena.

MELON AND CUCUMBER CULTURE (J. J.).—It is solely a question of taste as to whether Melons or Cucumbers would be the more profitable occupants of your frame. Little Heath is the best Melon for your purpose, and one plant in each light will be ample. For raising the plants a night temperature of 60° is requisite, and a day temperature from sun heat of about 80°; you should also have a bottom heat of 80° from fermenting material. Unless you have sufficient dung and leaves to maintain the heat stipulated it would be advisable to defer the sowing of the seed until early in May, when the sun heat becomes more powerful; or you might, perhaps, induce a neighbouring gardener to raise a couple of strong Melon plants for you. The amount of manure you propose using is certainly not sufficient for commencing Melon culture on the 15th inst. If a genial temperature is provided the plants will not be ready for planting out until a month after the seed is sown. We advise you to obtain stout plants about the middle of May, and plant them out then in warm soil. The seed may be sown in pots, as also may seed of ridge Cucumbers—Stockwood Long Ridge being the best. You may, perhaps, raise the Cucumber plants by sowing at the time and in the frame you propose, but the temperature would be insufficient for raising Melons, even if the glass were covered with mats at night.

WORMS IN LAWN (Omega).—Soak it with lime water, and repeat the soaking when fresh wormcasts appear.

PEAT CHARCOAL (H. S.).—It is applicable to plants the same as common charcoal. We do not think its use would prevent the Potato disease, but it might check its progress.

AMATEUR (S. H.).—A labourer employed regularly in a gentleman's garden under a professional gardener, and for whom duty is paid to Government, ought not to exhibit and take prizes in the "amateur" class of a floral and horticultural show.

DESTROYING GREEN FLY AND RED SPIDER.—"R. G. M." asks for some fumigator, not tobacco, that will destroy these vermin. Tobacco smoke even will not kill red spider, and frequently syringing the plants is the best mode of keeping that insect in check. Syringing with a solution of quassia will destroy aphides, and will not injure or disfigure the foliage of plants. A quarter of a pound of quassia chips boiled for a quarter of an hour in a gallon of water will be of sufficient strength to be diluted with four or five gallons of clear water for syringing purposes. We have heard that bruised

leaves of the common Laurel will, if kept fresh in plant houses and frames, prevent the increase of green fly, but we have not tried this preventive.

ANNUALS (G. Davis).—Write to Messrs. Carter for the names; the firm exhibited annuals frequently, and we do not know the particular occasion to which you allude.

BEGONIAS (A. M. T.).—They are so much withered and some of them flowerless that we can only recognise two of them—namely, 4, *glaucofolia*; and 5, *Dregei*.

SALSAFY CULTURE (W. Lincoln).—Sow in March and April in an open situation in shallow drills 9 inches asunder; scatter the seeds thinly and cover them half an inch deep. When the plants are 2 or 3 inches high thin to 10 inches asunder. During very dry weather water occasionally very plentifully, and if half an ounce of guano is added to each gallon of water it will be very beneficial. They will have large roots by September or October; and in November, when the leaves begin to decay, a quantity may be preserved in sand for use in time of severe frost; but those left in the ground will not be injured. In spring, when those remaining in the ground begin to vegetate, the shoots when a few inches high may be cut for use as *Asparagus*, being excellent when quite young and tender.

NAMES OF FRUITS (Connaught Subscriber).—London Flippin.

NAMES OF PLANTS (J. C.).—1, *Pellaea rotundata*; 2, *Asplenium lucidum*. (S. M.).—1, *Polypodium angustifolium*; 2, *Nephrodium effusum*. (W. H. A.).—*Davallia Novae-Zelandiae*. (R. E.).—1, *Asplenium flaccidum*; 2, *Cystopteris fragilis*; 3, *Pteris serrulata*; 4, *Nephrodium Filix-mas*, var. (*Constant Reader*).—1, *Goldfussia isophylla*; 2, *Eranthemum nervosum*; 3, *Eriostemon intermedium*; 4, *Polygala oppositifolia*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF A BUTTER-MAKING DAIRY.

WE propose at present to enter upon the subject of conducting a home-farm dairy composed chiefly of Channel Island cattle, but intend at a future time to take up the subject as it refers to short-horned and other cattle. We find that in most parts of the kingdom that the Channel Island cattle are great favourites on the home farm, particularly where there is a considerable portion of pasture and park land. Under the name of Channel Island cattle we have three breeds included—viz., the Jersey, the Alderney, and Guernsey. The two first named are now so nearly allied in breeding that it is very difficult for a novice to distinguish between them; nor do we consider it of much importance which we select, for the late and modern fashion in breeding as to character and colour is quite different from that which formerly prevailed. Formerly it was required that the animals should not only be good milkers, but their colour and markings were a point of importance, especially when desired for ornamental cattle in the parks of the wealthy. And so it is now, but the fashion has changed; for instead of the mottled markings of grey and white, or lemon and white, which used to prevail, the animals are now dressed differently, and required to wear a coat of self colour, the choicest colour being considered silver-grey or fawn colour, and if without a spot of white upon them they are more approved. The Guernsey breed is very distinct compared with Jerseys or Alderneys, having been as long as we have known them mostly of a self colour of yellow or reddish yellow, being much larger and better grown, though coarser in appearance and stronger in the horn, with more hair and more aptitude to fatten than the Jerseys. The chief distinction of the Guernseys is the extremely rich milk and high colour of their cream; but they seldom give so much in quantity as the other two breeds, and are not often used alone in a dairy, because in summer time their cream is too rich. As an instance we may mention that we had a dairy composed entirely of this breed, but were obliged to sell some of them, as the butter was so oily that it could not be made up and printed, and instead of being of the bright yellow hue so desirable in butter it was of a colour almost approaching that of bees' wax. It should therefore be considered that these animals should never form more than one-fourth or fifth of the number of cows kept, the object being to give the butter a deeper colour where poor milch breeds are kept. When, however, a crossbreed is required for a butter-making dairy, the Guernsey makes an admirable cross with the Shorthorn for improving the quality of the milk without deteriorating the value of the animal for fattening.

All kinds of the Channel Island breeds are extremely docile

and gentle animals; the males, on the contrary, often become vicious and comparatively unmanageable after two years of age. It is no wonder the beautiful and quiet Jerseys become great favourites, and particularly in those cases when ladies take an interest in the ornamental cattle of the park pastures. In order to have cows of the most approved style and quality they should be bred or selected with the following points:—Self colour; the breed both on male and female sides reputed for producing a large quantity of milk and rich and yellow butter; head small, fine, and tapering; eye full and lively; muzzle fine and encircled with mealy white; horns polished and a little crumpled, tipped with black; ears small, of a deep yellow colour within; back level from the withers to the setting-on of the tail; chest deep and nearly on a line with the belly; hide thin, moveable but not too loose, well covered with fine and soft hair of good colour; barrel hooped and deep, well ribbed home, and having but little space between the ribs and ribs, with tail fine; fore legs straight and fine, thighs full and long, close together when viewed from behind; hind legs short and bones rather fine; hoof small; hind legs not to cross in walking; udder full, well up behind; teats large and squarely placed, being wide apart; milk veins large and swelling. These are the points now kept steadily in view by the breeders in the Channel Islands, and we can do no better than adhere to them. Large numbers of cattle are imported every year, but the demand for them is so great that many are imported from the Channel Islands which were never bred there, coming probably from Normandy and Brittany, and after a short location are sent to England as Channel Island cattle, and there is such a likeness in many respects that it really requires a person accustomed to the business to distinguish between them. Generally speaking the inside of the ear will decide the question, for if the inside of the ear is not of the orthodox yellow colour they may be discarded as counterfeits instead of pure well-bred Channel Island cattle, notwithstanding other similarities.

In dairy farming for butter we must remark that when properly and industriously attended to it is one of most profitable points or practices connected with the management of a home farm. But having stated the requirements connected with Channel Island cattle we do not by any means wish to exclude the crossbreds from the home farm, for many may be selected if judiciously done that not only yield good profit but prove also very handsome and ornamental animals on the pastures. One important question, however, crops up—whether it is better to breed our own stock or be contented with such opportunities as may occur, and purchase the best we can to supply our wants. This will very much depend upon the neighbourhood, and the chances we have in our local markets of obtaining what we want of the required style, breed, and quality of the animals. There is, however, to our mind one point or matter which over-rides all the others—that is, that in breeding like begets like, and if our stock entirely, both male and female, represents our requirements we are pretty sure of a succession of stock, certainly far beyond that which we can ever expect to obtain as a whole by a system of continuous purchases, particularly if we require Channel Island cattle. Not only is it true that in the case of buying stock bred in this country that it requires a considerable time before the animals become accustomed to the change of soil, management, and climate; but it is doubly so with imported stock, because in their native islands they are cared for and treated as kindly as the farmer's children, at any rate as pets, and managed in that peculiar manner that when they are brought to this country the change is so great that we have often found several years elapse before they will answer the expectations formed of them. One of the greatest objections to the Channel Island cattle as we formerly knew them was that in the event of non-breeding or old age they were comparatively worthless, and must be sold at small value as compared with the original cost. But when they are bred or bought possessing the points above named we may feel assured that generally speaking they will pay for feeding and fattening for the shambles.

Let us now refer to the provision of pasture and food for the

cows, and it is a remarkable fact that in the Channel Isles the cattle are generally more healthy and free from epidemics than in most countries. This is no doubt attributable in some measure to the saline particles which float in the air over the islands and are deposited to some extent on the herbage and tend to its salubrity and the early production of grass and vegetable food for cattle by raising the temperature of the soil. After heavy gales it is often found that the grass in these islands has a strong saline flavour, and so partial are the cattle to this flavour that they will greedily devour grass which has been watered with sea water, which they had previously rejected. This circumstance teaches a lesson which we ought not to be slow to learn, as we all have salt at command. There is no question that any pasture or park land situated in the midland counties or out of reach of the sea breeze would be greatly benefited by the application of 2 or 3 cwt. of salt per acre in the spring months, for not only would grass be earlier but more wholesome for the cattle. In corroboration of the effect of salt in dairy cows, they always do best to have a lump of rock salt which they can resort to at all times, whether in their pastures or pens. Early grass is always an important point in a butter-making dairy, much more so than a dairy kept to supply milk only in the towns, because good milk can be obtained by the consumption of roots and every kind of vegetable produce; but this is not exactly the case with milk for butter, because some roots, it is well known, although they may tend to produce a full quantity of butter, yet the quality and flavour cannot always be depended on. On the contrary, grasses both of pasture and arable produce will generally give butter of the best quality, unless, as it is sometimes, affected by some noxious weeds which may happen to grow in conjunction with the grass. Most notably is the Italian rye grass, the produce of arable lands, an important factor in the early feeding of dairy cows, nor can any objection within range of our experience be brought against it; on the contrary, it is not only one of the purest of growths which can be used for feeding cows, but at the same time the earliest and most productive, giving also a capital succession of food during the summer. It has been often said that liquid manure is the best for early and abundant production; this is probably the case during the summer months, but in early spring liquids are apt to chill the land, thereby retarding the progress of growth as compared with nitrate of soda, which is the best for early produce.

(To be continued.)

WORK ON THE HOME FARM.

The horse labour on the farm has lately been removed from the arable land by the snow, frost, and heavy rains which have prevailed at the end of March. As a consequence the rolling of the pastures has been going on to good effect, also carting dung from the cattle yards to heap for future use. It answers a good purpose to mix this with earthy compost for the pasture land; and whilst some of the horses may have been carting dung, others may have been well engaged in carting roadside earth, to be mixed with dung or heaped in store for other purposes, such as to be broken fine and screened when dry in the summer months. Now this matter leads us to consider important points connected with home-farm management, and which we can with confidence recommend—viz., that all the dung and compost should be used entirely upon the pasture or park land, and that the arable land should be manured with artificials, such as guano, nitrate of soda, and bone superphosphate only. In our own management upon home farm lands this system has raised various properties from the depths of poverty into the highest state of fertility, and as this matter is so intimately connected with the work of the farm we proceed to give reasons for our adopting so unusual a course of management. Firstly, there being no manure or compost to be carted on to the arable land there can be no hindrance at sowing time, for we have often known in difficult seasons the seed time lost whilst the manure was being carted on to the land; whereas if artificial manures only had been used, the work of sowing manure and seed would have proceeded simultaneously without let or hindrance. On the majority of soils, both light and heavy, the artificial manures if properly selected, of good quality, and judiciously applied, are quite equal if not more efficacious, value for value, than dung or compost, which involves in all cases heavy costs in carting, laying-out, and spreading; and it must be remembered, too, that the carting and laying-out of dung or compost on grass lands can proceed during nearly the whole year, except after the pasture has been laid-up for hay. Secondly, dung and compost is better for pasture land, because these substances are a mineral addition to the soil, which is so much more important on the pastures where the land is not moved; whereas the arable land is always supplied with minerals, or may be, by the actual cultivation and tillage going on in preparation for crops. Therefore the essence and active principle of manures is readily and without inconvenience supplied by a dressing of artificial or ammoniacal manures.

The men will now be employed in couching, in which work the women and boys may assist. If this period of the year is missed for cleaning the land the opportunity may be lost for land in-

tended for mangold. In working the land when foul we prefer the new kind of lifting-drag or scarifier made by Howards of Bedford. This is a great improvement upon the old-fashioned drag, as it combs out the grass and weeds, lifting them to the top to be dealt with by carting off the land, either to put into heaps or lay out on grass land, as it proves good manure. We prefer this to burning on the land, for we hold it bad farming to burn anything which will rot. Besides, where couch and weeds are carted-off it can be done without so much time and labour being spent to get it dry enough to burn, the work is not hindered by showery weather, and the next ploughing can be done without delay. The late rains will also have enabled the horses to be employed in rolling the pastures where laid-up for a hay crop. We have been over much land lately of a rather heavy and strong nature resting on chalk. On such lands we find large flint stones not very numerous, but still enough to interfere with certain work on the land, such as cutting corn, grass, &c. Many of these stones are called provincially by the term rags, and are generally picked up and then carted away, but we prefer to break them with an iron hammer; they will when broken to about the size of a hen's egg work-in and roll into the ground, and instead of being an impediment to cultivation will improve the working of this heavy land, make it plough lighter and work easier. Earth heaps should now be turned up, so that the different kinds of soil in them may be mixed and the weeds become rotten. When earth heaps are to remain during the summer, instead of allowing them to remain idle we plant vegetable marrows of the large cattle sort, otherwise we plant pumpkins of the early French variety, also gourds and the Ohio squash. These grow with great luxuriance, keep the weeds down, and the fruit is capital food for cows and pigs. We shall return to this subject another day.

FORTHCOMING POULTRY SHOWS.

WE have before us the schedule of the Bath and West of England Society's next show to be held at Oxford in June. Rule 12 informs the public that "important alterations having been made, exhibitors are particularly requested carefully to examine the prize lists and regulations of the Show." The alterations are indeed important, and not altogether improvements; among them we observe—1, Single birds are shown throughout all the poultry and Pigeon classes in lieu of pairs of hens and pairs of Pigeons. The advisability of this change is, of course, a matter of opinion. 2, The £5 cups are cut down from about fifteen to two! Of late years these have been given for the best cock and best hen in each section; now they are only offered for the best bird of each sex in the show. 3, Entry fees are raised from 5s. to 6s. in the poultry classes, and from 2s. 6d. to 5s. in the Pigeon classes. This we think ungenerous, and utterly unworthy of so old-established and rich a Society, especially when the number of cups is so greatly reduced, and the cost of food must also be considerably lessened by the exhibition in many classes of single birds where two were formerly shown. On the other hand we may note some slight improvements. 1, The classification has been extended; there are sixty-four classes for poultry and twenty-one for Pigeons. Among the new ones are classes for Minorcas, Leghorns, and Langhans (the latter apparently privately subscribed for), and two for the best cockerel and pullet respectively of any variety hatched in 1878. This addition strikes us as a purposeless one. Where chickens are shown they should be properly classified, or promising birds may be much trashed to no purpose. 2, Divided baskets are apparently allowed for poultry. This we always consider a great boon, which should everywhere be granted.

We have also before us the schedule of the Epworth Show to be held on May 8rd. It is on the whole a good one, though we cannot consider a schedule a complete one which contains no class for Dorkings. Single birds are shown throughout, and the prizes are £1, 10s., and 6s. There are forty classes for poultry (eleven of these being for Bantams), with three sectional cups of three guineas each; twelve classes for Pigeons, with three-guinea point cup, and a two-guinea cup for the best bird. There are also classes for Cage Birds, Dogs, Rabbits, Cats, &c.

PIGEONS—HINTS TO AMATEURS.

If some of your correspondents who are experienced in the fancy would, under some such heading, detail us their experience when "apprentices" to it, no doubt much good would result to their younger brethren. In my own case I am always on the look-out for anything that may tend to increase my knowledge of Pigeons, and yet find very little in any of the journals that regard the fancy in a favourable light that would at all enlighten a young fancier as to the proper points, markings, &c., of some of our birds, such as Tumblers, Baldheads, Beards, &c., with some of which he would usually commence his career. I am sure if any gentleman would kindly take into consideration the claims of his younger brethren in this direction and let us have a little information, he would be earning the thanks of many who cannot get their

birds anything like perfection because they do not know how.—**AMATEUR.**

[In compliance with the wish here above expressed I will say a few words concerning Flying Tumblers, especially for those who are beginners in the fancy; with an eye, too, to those who desire to keep Pigeons for amusement and for ornaments to their homes—and very home-like and pleasant do a few well-shaped and coloured fancy Pigeons look, the tamer and more domestic the better. I shall also bear in mind what I said in a recent number, that of March 7th, about the many, for many I am sure there are, who have no idea of showing—nay, who would not for a moment care for the expense of sending their birds about the country; yea, who much prefer having their pets at home, who do not want to break pairs, or shift eggs, or lose them. The exhibitor is one class of fancier; the man or boy, or lady is it? who likes a few fancy Pigeons always at home is another. There is room for both, for this is a wide world.

"AMATEUR" mentions Tumblers. In regard to these birds the older Pigeon books especially, and little handbooks on the subject, have been sad deceivers. They have spoken of Tumblers as having perfectly round heads, tiny beaks, and in the same breath of their flying many hours, and they implied too that they all tumble in a wonderfully systematic way without one doing differently. This is not so. The very small-headed birds with tiny beaks are the high-class (so called) Tumblers, whose heads may be round as marbles; but they are so from pressure and art, not from nature. Their poor beaks are very tiny because pared down to the quick, and I have seen them bleeding from the process. Tumble! they simply cannot. Fly for hours! quite impossible. They can only fly with weak fluttering wings about an aviary, and in a little wind would be dashed against the gable end of a house and killed. Now, the flying birds are none of these; they are not atoms, but good-sized Pigeons. Their heads are roundish, not round; their beaks are stout and strong and somewhat short. They are plump-bodied and dapper walking and looking birds; but they will not fly for hours. Take the word of one who has kept them for years. Sometimes after being shut in, or from some atmospheric cause probably, they will fly for a long time, but rarely even an hour. Then as to their tumbling. Very few of them tumble at all, and if they do it is the worst shaped as a rule and those that have a few feathers on their legs, both which things greatly take off from the neat Tumbler appearance, so that no young amateur must be disappointed on turning his birds out after they have bred and are used to their home, and—particularly remember this—have had a wire cage in front of their home, and hence they could see all the features of the place near. Now, when on turning out his or her (I prefer to think of the her; some gentle school girl perhaps) Pigeons—these Tumblers I am writing of—if she does not see them all tumble as the books talk about, she must not be disappointed. Some will back but not go over, as if at the last moment their courage failed them; some will make a great display with their wings, coming down a long way on them, but head foremost, not head-over-heels. But there may be in the number one or two which you have not cared about in the loft—not at all your pets, and yet actually over they went, and then up again among the rest. There over and over they go. Now you must notice (be sure you do) which these really are, and do not fancy that it is that pretty little hen you are so fond of. A word in your ear. Pretty things are not always the best—no, not even among human beings. Pick out these best tumbling birds, match them together, and shortly you will have a flight of real Tumblers. This selection is a pretty task. I have ridden when a lad—aye, and afterwards too—miles after a real Tumbler that somehow or other I have heard of; then I have seen the bird at its performance, that it was not a backer or a skimmer but an actual Tumbler, and then bought it. I used to find the pursuit of good birds a very interesting object for a ride or a walk.

Next, about colour in Tumblers. Without an atom of doubt the Black and White Baldheads look the best in the air, and are often the best to tumble. As to look, the Black is of course a most distinct and perfect contrast to the White. Red is not amiss. A Blue Baldhead is sweetly pretty on the ground, but the light sky-blue of its feathers looks too pale in the air. Still, all are very pretty birds; and not less pretty—nay, more pretty than any, is the Yellow Baldhead, though I never had one that would tumble, though many tried but failed.

Then as to the colour or exact markings of Baldheads. Now the books will tell you they must have clear white heads. Not one in a dozen but has one or two black feathers, particularly over the eye. The books say clear white thighs, but very often they have dark or darkish thighs; and this makes the Red bird look worst in the air, as the red on the thighs is a lighter red than on the body. By pains, and care, and selection you may get up a flight in time very fairly correct in marking. One marking you must secure, and that is white wings—I mean, of course, white flight feathers. This is indispensable, or nearly so, to the beauty of a flight of Tumblers, as the white wings show so well in the somersaults. Another thing I would say: As there are Tumblers that under-do the tumbling, so there are birds that over-do in the

matter. These poor things are really to be pitied; they in time cannot fly upwards to a nest without tumbling, until they are so conscious of their trouble that they cease to attempt to fly for fear of breaking their heads on the ground. Still, though their case is no doubt one of brain disease, yet moderate tumbling in high-flying birds is, I hold, a sign of health, and the tumbling is frolic and fun and a source of enjoyment to the birds themselves. There are other Tumblers which fly a distance, and with the utmost difficulty from their excessive tumbling manage in a scrambling way and after much effort to get home. There are also the Rollers, owning Birmingham as their home, or original home, that after ascending roll over and over ten, twenty, to thirty times, and, if they do not hit their heads against a chimney-pot, come all right to the ground, and when they do get there they gasp and look around and seem to say, "There now, what do you think of that? It's all very well for you to look at, but it's awful dangerous work, and I feel very bad after it; and don't, please, drive me up again, good master." Now, I write from experience, having kept all manner of Tumblers, and being excessively fond of the birds. Strive by crossing to obtain high-flying moderately tumbling birds, but see them tumble before you buy them. Let them be as pretty as you can, and with white wings if possible. They are charming Pigeons. Up they go, and yet do not scatter wide, but keep Skylark-like just above their home.

I will prattle more about other varieties of Tumblers in another paper.—WILTSHIRE RECTOR.]

VARIETIES.

UPWARDS of £2000 has been promised on behalf of the fund for holding the proposed great agricultural Exhibition in London next year. Her Majesty and other members of the Royal Family, with the Dukes of Devonshire, Westminster, and Bedford are amongst the principal donors. The Council of the Royal Agricultural Society express themselves sanguine as to the obtaining of an appropriate site within the metropolis for the Exhibition.

—A BILL brought into Parliament by Mr. Clare Read to amend the Adulteration of Seeds Act, 1869, enacts that section 2 of the Act now in force shall be read as if, instead of the words "The term 'to dye seeds' means to give to seeds by any process of colouring, dyeing, sulphur-smoking, or other artificial means the appearance of seeds of another kind," there were therein inserted the words, "The term 'to dye seeds' means to apply to seeds any process of colouring, dyeing, or sulphur-smoking."

—WE have received from Messrs. Ulbricht of Hamburg a most imposing list of their poultry and pigeons for sale; in fact, it is an almost complete list of all the known varieties of domestic poultry and pigeons, among which we observe many which we had believed to be extinct. Some of these, however, are not priced, and we fancy that the Messrs. Ulbricht can hardly have them in stock—e.g., the rarer kinds of Polish and Eastern Bantams, but must insert them in their catalogue as breeds which they believe it possible to procure.

—GOOD service is being done by the Royal Agricultural Society by determining by analyses the value of feeding stuffs and manures vended by certain dealers at unjustifiable prices. Amongst some of the cases recently published we find details where "meat and bone" manure had been sold at £5 10s. per ton, which was only worth £2 2s., and "nitrophosphate manure" had been sold at £9 per ton which was scarcely worth 15s. Analyses are effected for members at a nominal sum by the consulting chemist of the Society. The purchasing of fertilisers is a matter of such great importance that too great care cannot be exercised in the selection of dealers in the various compounds now offered to the public.

—A CORRESPONDENT writing in the *Prairie Farmer* on the comparative merits of Italian *versus* black bees, states that for three years he kept the two races with the same attention and care given to each, and he could not fail to see in that time the superiority of the Italians, which was evident in every season, but more so in hard seasons, when the Italians stored double the honey that the natives did. With the Italians he finds some stocks much more energetic and prolific than others, and concludes that the apiarist should if possible breed only from stocks having most good qualities. This careless breeding may be cause of, and doubtless is, of some bad reports made. Those raising bees to sell should be careful in their selection of stocks to rear queens from. This, we think, coincides with the experience of our able correspondent "A RENFREWSHIRE BEE-KEEPER."

—A CORRESPONDENT of the *Irish Farmers' Gazette* communicates the following experience on potato-growing:—A few years ago I planted an increased growth of hops, on 12 acres of which I planted potatoes. Betwixt the rows of hops, which are planted 6 feet apart each way, I applied a ton of shoddy, 6 cwt. of superphosphate, and 4 cwt. of kainit per acre broadcast, and well cultivated or grubbed the land betwixt the hops in both directions; then in the north and south direction planted one drill of potatoes (between the hops) with whole sets 15 inches apart. They were horse and hand-hoed thoroughly four times;

the growth (notwithstanding the hope) was the strongest and most luxuriant I ever saw, and although the drills were 6 feet apart, the produce was over 4 tons per acre, which made over £20 per acre delivered at the nearest railway station. The sorts were Regents and Victorias; the latter were the heaviest crop, but more diseased. Considering the luxuriance of the crop they were wonderfully free from disease. I also found that mangold wurtzel flourished on shoddy and the same manures better than with 20 tons of good dung instead of the shoddy. The soil was moderately strong on the Kentish rag, which is a bastard limestone celebrated for growing the Golding hops. We may add that some of the finest crops of Grapes we ever saw were produced by Vines growing in borders which had a liberal admixture of shoddy in their formation.

ABOUT ANCIENT WRITERS ON BEES.

In reading up old writers on bees one is struck with the wild notions and fancies of many of them. For centuries little knowledge was gained of the history and management of bees, and therefore little could be given in writings. Amid heathen darkness Dr. Charles Butler, who lived in the time of Charles I., began to feel his way to facts, to read bee life through his own eyes, and expose the ignorance of others who had gone before him. Probably Butler was the first to discover that the monarch of a hive is a female; that bees prior to swarming send out scouts to find a new habitation or branch to settle on; that bees gather farina to feed their young, and gather it from one kind of flowers only in each journey, and never make wax of it, seeing that hives full of combs have no more wax at the end of the year than they had at its commencement, and that real wax falls from the bees on their boards in the work of building combs. The scales or flakes of wax which he found on the board Butler melted, and thus discovered that wax is altogether a different thing from farina. Thorley, who wrote one hundred years after Butler, proved that wax is concreted under the scales of the abdomens of the working bees. The researches of other and later writers led to the same conclusions, and Huber was probably the most celebrated expounder of these and other matters of bee history at that time.

In looking back along the line of the ages one is struck with the great amount of attention that has been given to the honey bee, its natural history and management. Amid the discoveries of science and the mysteries of life and creation the little busy bee comes to the front to claim and secure attention. Where else shall we find a subject of greater interest than a bee hive, or one so full of social life and wonders? Though many of the most thoughtful men of all ages—kings, philosophers, poets, historians, and travellers—have "walked round" the bee hive and tried to dive into its mysteries the subject is more attractive now than it ever was before, and presents problems for solution that will puzzle the great masters of this enlightened age. In a bee hive we have a community of wonderful creatures—a government the most perfect, unapproachable architecture, loyalty that never wavers; in a word, a community remarkable for industry, economy, cleanliness, courage, and ingenuity.

Much has of late been done by simple practicable teaching to popularise bee-keeping and spread a knowledge of bees. Much remains to be done. Everything in the bee world indicates progress. Many ladies and gentlemen throughout the country, and men of business engaged in rural pursuits, are ever seeking to promote the happiness of the cottagers around them, and as a means to this end they are now encouraging the culture of bees by offering premiums for honey, &c., at our horticultural and agricultural exhibitions. I sincerely hope that these laudable endeavours will be repeated and multiplied from year to year, and everywhere crowned with success. In drawing up schedules of prizes for bee and honey shows it appears to me that some limitations should be introduced to prevent one or two leading men from taking too many prizes at one show, and that secretaries and treasurers or other officials of societies who draw up such schedules should obtain or be prohibited from competing for the best prizes. No competitor should be appointed to act as a judge. At some of our largest bee and honey shows this principle has not been practised, and hence confidence has been broken and societies have come to grief. Meanwhile, and notwithstanding such mistakes and drawbacks, the knowledge of the practical management of bees is spreading far and near.

All I have to say here as to the study of the natural history or habits of bees is this—that there is room for another Huber on the earth, and plenty of work for him to do. The story of bee life has never been fully told: the profound mysteries of a bee hive have not been all unfolded by past discoveries and descriptions. There remains ample room for future research, questions to settle that will require a great amount of attention, energy, enthusiasm, and experiment. I cannot wish I were young again to write another book, for that cannot be; but in case someone who reads this letter may wish to study bees for himself or herself, with a view to write an accurate and comprehensive work on the habits of bees, I will here suggest that the safer way would be to read

some of the best works on the subject, and test every point by experiment and thorough examination. Go through the surface opinions of others, and dig down to the roots of every question. It is not long since a severe student of physical science, natural philosophy, and natural history, said to me that he had lately been reading the history of the cold-blooded animals, and found that all the modern works on the subject were simply the copies or reproductions of ancient writers; and he asserted that the history of the cold-blooded animals could not be written without a fresh and thorough examination by fresh men and honest students of nature. Many important and interesting discoveries have been made in bee history, and these discoveries have been well and repeatedly told, but, as has already been said in this letter, there is yet much to discover, and an inviting field for investigation by experiment. If anyone were to ask me to suggest a title for a fresh and original work on bees, I would say "Instinct and Reason of Bees" would be a good name, and one indicative of mysteries not easily fathomed.—A. PETTIGREW.

OUR LETTER BOX.

CHICKENS (W. Whitehead).—No one could answer your query peremptorily. The chickens probably will be the offspring of each cock, the latest-laid being by the Cinnamon.

RED-FACED SPANISH FOWLS.—"Northern Subscriber" and many other correspondents ask where eggs of these fowls can be obtained. It would repay anyone who has them to advertise.

REMARKS.

- 3rd.—Fair morning; rain commenced at 9 A.M. and continued the greater part of the day; very fine sky at sunset; starlight night.
4th.—Very fine sunny day; misty in evening, but fine.
5th.—Fine bright morning, overcast after 9 A.M., showers and sunshine at intervals during the day; hail at 9.36, and thunder at 1.43 and 1.44; slight fog in evening.
6th.—Fine in early morning; very foggy and dark from 8 A.M. till 12, afterwards fair and pleasant; fine evening.
7th.—Bright sunny morning, windy and fair rest of the day; bright starlight evening.
8th.—Bright sunny morning, very high wind and much dust; a sunny day, but not pleasant; starlight evening.
9th.—Sunny morning, dull, but fair afterwards.
Nights still very cold, but days warmer in spite of drying winds.—G. J. SYMONS.

COVENT GARDEN MARKET.—APRIL 10.

No change has occurred in the supply or quality of fruit and vegetables during the week.

MOWING MACHINES.

NEXT to the adaptation of hot water for heating garden structures the mowing machine has proved the most valuable invention and the greatest aid to gardening practice. It is emphatically a labour-saving implement, and such is the excellence to which it has been brought that the quality of its work cannot be equalled by the most expert mower with the scythe. Possibly it may be true that Daisies and similar weeds may have increased on lawns since they became so smoothly shaven with the machine, but any little inconvenience arising from the presence of the "wee crimson-tipped flower" during a few weeks in spring is more than counterbalanced by the velvety smoothness of the turf during the remainder of the season; the mowing machine is in fact indispensable to gardens large and small where lawns have to be kept in order. Machines are adapted in size, too, for all lawns, as they can be had to cut any width from 6 feet down to 6 inches. The improvements that have been effected during the past twenty years are also very great, and can hardly be appreciated except by a comparison of an old noisy cumbrous machine of a quarter of a century ago with one of more recent manufacture.

It is surprising how long a mowing machine will continue serviceable with care and good usage. I have had a machine in my care that has been in regular use for more than a quarter of a century, and it is still in good working order, but does not work with nearly the same ease as the machines of the present day. It is a 24-inch machine, and it is laborious work for three men to use it on a level lawn. Two years ago its use was relinquished, not because it was worn out, but because two new machines in its place have effected a great saving of labour: and this brings me to an important consideration in respect of selecting a machine that will give the greatest amount of satisfaction.

The first point I would urge is never to retain an old-fashioned machine, even if it does its work well, because every day it is used it involves an extra outlay of 3s. (a man's wage), which soon amounts to a considerable sum. I have arrived at this fact from experience, having found that two men can do more work, and do it more easily, with a modern implement than three men can effect with an ancient one of the same size.

Another point of importance that I have determined is that in many, and probably in most, gardens a number of small machines, each capable of being worked by one man, are more profitable than a lesser number of larger machines requiring two men to work them. Take the case of a garden where three men are employed, including the gardener. There is a considerable extent of lawn, broken up, it may be, by jutting points of shrubberies and many flower beds. In such a case it is usual to have a 20 or 24-inch machine worked by two men; but if each man is furnished with a 14 or 16-inch implement very much more work will be done in a given time. I have proved that point by direct experiment. Another, and often a very great advantage in having two small machines instead of one large one

is that the gardener often requires the aid of a man in doing some other and urgent work when the mowing also is about equally urgent. By taking a man from the large machine the mowing is stopped altogether; but when two small machines are employed a man can be withdrawn for a time and the mowing proceeds with the other. If only two men are employed in a garden having a very large lawn the advantage of having two small machines instead of one large one is still greater than where three men are employed. The rule of a multiplicity of small machines holds equally good when the lawns extend to several acres and where a number of men are employed in working the machines. This applies to lawns having many slopes, nooks, and flower beds, and where horse or donkey labour is not available. The plan in such a case of furnishing each man with a machine of a size that he can work it easily and expeditiously is the most economical to the owner of the garden and the most satisfactory to the gardener. I have been informed that this plan is carried out to a considerable extent in the London parks and gardens, where it is necessary to restrict labour to the lowest point consistent with the efficient performance of the requisite work.

In the case of the garden under my supervision, since two small machines were substituted for one large one the garden has been kept in much better condition, and a return to the old plan would be regarded as something like a calamity. In a larger garden in the same locality five labourers and two 24-inch machines were employed for several years. Eventually three small machines were adopted in the place of the two larger, and the garden is now apparently as well worked with four labourers as it was before with five. The three machines did not quite cost £20, while the saving in labour yearly exceeds £40, wages being 18s. per week. The gardener at the time demurred to the withdrawal of a man, but I think that he would not go back to the old plan if he had the opportunity. Before machines were introduced six labourers were always employed in the same garden, so that a clear gain according to the present rate of wages of £80 a year was effected by employing machines, the odd £13 (the wages of the men amounting to £93 12s. per annum) being quite sufficient to supply the implements and to keep them in good working order.

The size of machine for one man to work can only be determined by the nature of the lawn; if it is tolerably level and not mossy a man will work a 16-inch machine, but if the lawn is of a contrary character he will do more work with a 14-inch implement. If a doubt exists as to the right size to select, it is safer to err in choosing a machine rather small than one so large that it cannot be worked easily and quickly. It is a great mistake to have machines that tax the strength of the men to the utmost when using them, for work done under those conditions means loss to the men and the master too.

It is important that mowing machines be well taken care of both in the interests of master and man; the former by their lasting longer, and the latter by their working easier. They are like clocks and watches, and will not "go well" if they are permitted to become clogged with oil and dirt,

or if their works become rusted. The machines should always be cleaned after being used. This is a tedious matter if set about in a wrong manner, but quite easy when rightly done. The plan I have adopted for many years, and now always insist upon, is to rinse each machine with hot water before placing it away. A large can of water is sufficient for a machine, and when "slushed" in it quite clears away all particles of grass and dirt. The hot water evaporates quickly and the machine dries at once: if cold water is used rusting often follows.

As to the comparative merits of the machines of various makers I have little to say. I have had them from three celebrated manufacturers who advertise in your Journal, and every machine works admirably. I am really unable to say which is the favourite of either myself or the men working them.

During "Daisy time" the grass box is fixed, and the grass and Daisy seed (if any) removed; but in dry hot weather the mowings are scattered on the lawn as the work proceeds.—
A STEWARD AND GARDENER.

LARGE VEGETABLES—ASPARAGUS.

"WHILE I am unable to concur with all that "A KITCHEN GARDENER" writes on vegetable culture, and especially in the matter of Asparagus, I observe with pleasure that he lays much stress on quality as opposed to mere size, and consequently coarseness, of garden produce. As feats of cultural skill I can understand a gardener pointing with a certain amount of pride to heads of Celery weighing 9 or 10 lbs., to Cabbages of at least the same weight, to Cauliflowers still larger, to Onions as large as Turnips, and Turnips as large as American Pumpkins. I was once proud of such feats myself, but I have lived long enough to see the error of many of my youthful ways, and amongst them that of growing gigantic vegetables. By growing produce of the character referred to we court loss in three different forms—1st, The extravagant use of manure; that is the master's loss. 2nd, The unnecessary expenditure of labour; that is the man's loss. And 3rd, The waste of produce in the scullery, which is both master and man's loss: to the gain of what? The pigs.

If it were possible to determine the value of masters' money and man's muscle that go to furnish the refuse tubs in the sculleries of the affluent, we should be startled at its magnitude. Scullery and kitchen maids have a summary mode of dealing with large and coarse vegetables. They do not consider long about them: they have no time for that, but dissect them boldly to their own satisfaction, and the benefit, let us hope, of—the pigs.

Did you ever see a domestic whose duty it was to prepare the vegetables for the cook take an Onion weighing 1 lb., cut a slice off it of an ounce, the quantity often required, and return the remaining 15 ozs. to the Onion-box or drawer? I never did. Did you ever see how dexterously a Cauliflower which in its normal state would fill a pail can be made to fit into a teacup? I have. Did you ever see a Turnip of the size of a child's head decrease a thousand times faster than the root ever grew, to the dimensions of a hen's egg. I have seen hundreds of such instances, but I never see one now without being reminded of the old Latin motto. *Reductio ad absurdum*. It is the same with Carrots and other vegetables, but the most absurd reduction of all occurs with Celery.

I remember when I was a vegetable boy digging Celery nearly or quite as tall as myself, and breaking in my clumsy way an occasional spade shaft over it. My next duty was to reduce the bulk of the Celery fully more than one-half at the rubbish heap, and then to take it into the scullery for Mary to have her turn at trimming. Another half of the portion left was then removed by Mary, and the residue, perhaps one-fifth of the original bulk, less rather than more, was fit for the master or the "upper servants;" the last-named individuals were so very particular, at least Mary said so, that the Celery must be small. I thought then in my boyhood that gardeners were on the "wrong tack" in vegetable growing, and since arriving at manhood I have found the truth of my early convictions. The growing of gigantic Celery, and Brobdignagian vegetables generally, for the tables of the gentry is a gigantic mistake, and I am glad that no such practice is advocated by "A KITCHEN GARDENER." But while I agree with your correspondent thus far, I have, as we say in the north, a "crow to pull" with him on growing Asparagus, which I will come to presently. I wish, however, first to narrate a little of my

recent experience on the growing of large vegetables and to place on record one or two rebukes I have experienced concerning them.

For several years I have been engaged in growing garden produce for a fastidious nobleman—one who knows what is good as well as most people. Moving in a high circle he has exceptional facilities for ascertaining the tastes of that section of society for which gardeners as a rule have to cater. This nobleman has in the most friendly manner impressed on me the great difficulty that families experience in obtaining vegetables exactly of the character they wish. He informs me that the one great topic in reference to garden products which is discussed by ladies and gentlemen is that gardeners will grow vegetables too large. When they are placed on the table in a small state it has come to be taken for granted that the cook has "made" them so, and the gardener who has grown them gets no credit for his pains. That is what I have been repeatedly told by "one who knows." I have endeavoured to profit by the hints, and since I have made it a practice of growing vegetables of half the size that I did formerly I have found it much easier to maintain a supply, and have given much more satisfaction as a cultivator than I gave previously.

I recollect an occurrence that taught me a silent but forcible lesson on the folly of growing large vegetables. The crop of Beet had been sown too early, and a warm showery season followed. The result was that in September the roots were much larger than usual. The crop, it appears, had been examined by the owner, and one day in my absence two men were ordered to follow his lordship with forks and wheelbarrows. He conducted them to the Beet bed, and told them to "dig up that Mangold Wurtzel and take it to the cows." "It's Beet for the house, my lord," one of the men ventured to explain. "No," was the prompt reply; "it is not Beet for the house, it's Mangold Wurtzel for the cows; take it away at once." I was, of course, greatly chagrined when I found what had occurred, and it was quite expected I should resign my charge in consequence of the "interference." The under gardener went so far as to say that if I could "stand that I could stand anything," but "old George," the vegetable man, whispered to me quietly—"Take no notice, he wants your place, sir; I know he does." I decided to let the young man wait. As a gardener I was "doing well," and was always met kindly; why should I punish myself because a master had done what he liked with his own? I resolved not to mention the circumstance; neither did the nobleman ever allude to it. He met me kindly as usual, but not to this day (and years have passed since the occurrence) has he once mentioned the large Beet. The rebuke made was silent but effectual, for I have never since sown the main crop until the second week in May, and have never since had coarse roots. The under gardener is waiting for the "head place" yet. He is a capital assistant, and I think is likely to remain an assistant, at any rate at —; no name, Mr. Editor, or I could not write half so freely, and I prefer freedom rather than fame.

Another rebuke I may mention. "Old George's" reply on this occasion was amusing. He was carrying a basketful of large Cauliflowers to the scullery for use in the servants' hall. His lordship met him, and the following dialogue ensued. His lordship: "Fine Cauliflowers, George; where are you taking them." George: "To the pigs, my lord." "Quite right," was the nobleman's reply, "let me see the pigs enjoy them." To the pigs they went, but the animals not being sufficiently hungry to eat Cauliflowers, only turned them over and left them. That was enough for the owner, who sent me word that the Cauliflowers were "too large—for the pigs."

My practice has since been to plant closely and to produce a greater number of close heads 3 or 4 inches in diameter, instead of planting widely and growing fewer heads a foot across.

Yet while I have always found that small vegetables of the kinds named have been most esteemed, I have found the case quite different with Asparagus. I have never had a call for small Asparagus except for soups; on the contrary, the finer have been the heads the more they have been valued. Experience has told me that superior Asparagus can only be grown by having the soil rich and the plants thinly planted. When "A KITCHEN GARDENER" asserts (on page 284) "that Asparagus planted 1 foot apart will produce as strong stems as those grown 3 feet apart, as it is only a question of soil," he argues against himself and his own practice of growing other vegetables. It were strange that close planting should

reduce the size of vegetables generally and not affect Asparagus. Nature knows no such vagaries. I will not further criticise your correspondent's letter, but will ask him to do as I have done—prove the matter by experience.

I do not accept the correction on the page quoted, that it is a mistake to write disparagingly on the crowding of Asparagus. At the same time I do not so much object to the growing of four rows in beds 4 feet wide, as recommended by "A KITCHEN GARDENER," if he had not recommended alleys of 18 inches between the beds. Long-lasting beds yielding superior produce cannot be maintained by such a system of overcrowding. To illustrate the matter practically let me state that nearly twenty years ago a number of Asparagus beds were condemned as being "worn-out." They were to be dug up and the best crowns forced. Instead of commencing at the outside of the quarter and clearing all the beds away every alternate bed was removed, and the additional air admitted to the plants remaining, with good cultivation, had such a beneficial effect on the condemned "worn-out" beds that they are profitable beds now. "A KITCHEN GARDENER" generally communicates sound and excellent practice, but he must permit me to say that I do not believe in growing Asparagus in a manner which necessitates the making of new beds every "ten or twelve years."—A NORTHERN GARDENER.

BALSAMS.

Few summer-flowering greenhouse and conservatory plants are more easily cultivated than Balsams, and few plants are seen, as a rule, in worse condition. If not killed they are spoiled by kindness. Balsam seed germinates quickly, and the plants grow with great rapidity in a moist high temperature, hence the plants are spoiled, the reason being, in nine cases out of ten, because the seed was sown too soon. Unless Balsams have abundance of light and air as well as heat and moisture good specimens cannot be produced. When suitable conveniences are provided, such as shelves near the glass in light well-heated houses, Balsam seed may be sown as early as March, and then with good attention fine specimens are produced during the summer; but in the majority of gardens such means are not afforded, and the plants, like many others, have to be grown on the best-way-you-can system. In such cases let me advise those essaying the cultivation of Balsams not to sow the seed until the last week of April or the first week of May. These plants are extremely ornamental when well grown. They need not necessarily be large, but may be flowered in 6 or 7-inch pots; then if they are dwarf, stout, and well branched, are covered with fine double flowers and rich green foliage, they are sure to be admired. But, on the contrary, if the plants are "long and lanky," requiring tall stakes to sustain them, and if the flowers are small and thin, the foliage greenish yellow, and insects numerous—as they generally are under such conditions—then Balsams are of all plants the most miserable.

If anyone wishes to see stout and sturdy young plants of Balsams let him note the thousands that are offered for sale in June at 1d. each by the costermongers of London. In very few gentlemen's gardens can such dwarf fat-stemmed plants be seen as those raised in shallow boxes by the market growers. The secret is that the seed is sown late and the plants are raised with but little artificial heat. If the seed is sown early and thickly, and the seedlings are raised in a moist close cucumber frame, and from thence transferred, it may be to a vinery, it is impossible to grow the plants in a creditable manner. Far better is it, when better conveniences than those are not afforded, to defer the sowing of the seed until the weather is warm enough to enable the plants being raised and grown in so-called cold frames, but which, however, are not "cold" in May, but warm if ventilated carefully during the day, closed early in the afternoon, and protected with mats at night; at any rate, they are warm enough for growing Balsams, and growing them well.

It may be well to state here that a very high temperature is not requisite for the germination of Balsam seed. If a temperature of 60° can be maintained in the soil, and the minimum temperature of the air is 55°, sturdy and healthy young plants can be raised. At those temperatures germination will be slow, and on that account the more satisfactory. When the seed is made to germinate quickly in a high temperature the cotyledons are small and thin, and do not give that nourishment to the young plant that it demands, and that it is the mission of the seed leaves to furnish; but, on the contrary,

when germination is slow the cotyledons are stout and fleshy, and the stems of the young plants become stout in the same proportion.

If anyone desires to perceive the difference in the size and texture of the seed leaves of Balsams raised under a high temperature on the one hand and a moderately cool one on the other, let him sow seed in a hot close cucumber frame, where it will vegetate rapidly, and sow also in rich light soil on a warm border in the open air in June. The difference in the plants a few days after appearing above ground will be found very striking and altogether in favour of those raised in the cooler medium. It is such plants as those raised naturally that the cultivator should endeavour to raise artificially. Their seed leaves will be large and fleshy, and will rest, or nearly so, on the surface of the soil when the first pair of proper leaves are formed. If that is accomplished a very simple but highly important phase in the cultivation of Balsams is attained. If after that stage a steadily increasing temperature is afforded, and abundance of light and air, if rich rough soil is provided, and the plants are shifted onwards before they are in any manner rootbound until they are placed in the pots in which they are to flower, satisfactory plants are certain of being produced; but, on the contrary, if the plants are raised at first in a very high temperature where they elongate rapidly, and are then transferred, as is so often the case, into a temperature several degrees lower, a check is given which will militate against the aim of the cultivator. The latter is a process totally opposed to Nature, and is a matter of more importance, perhaps, than is generally recognised by gardeners. Nature, it may be useful to note, sows her seeds in a cool medium, and increases the temperature with the growth of the plants. If growers of Balsams will do the same, and will increase the nourishment given to the plants in the same ratio, "spindle-shanked" Balsams will be the exception instead of the rule.

It is hardly necessary to go into details as to potting, &c., of these beautiful plants, since the general principles of culture are given which will enable the intelligent gardener or amateur to attain success if he seeks it with diligence.—A MARKET GROWER.

REMOVING RASPBERRIES.

I do not quite understand "WILTSHIRE RECTOR's" question, but I conclude that he considers it is best to remove the canes every few years. I will not find fault with him on that score, as I always hold that it is best for each one to practise that which they find serves them best; that is what I call really practical gardening. There can be no hard-and-fast lines drawn in such subjects as this.

In the matter of removing Raspberries occasionally there always will be difference of opinion, but simply using the word "occasionally" does not seem to me to be sufficiently defined; it may mean few or many years, but how many? The answer must be found in each one's experience. No stated time can be named as applicable in all cases. Age must not necessarily be a reason for moving Raspberry canes, for as long as they are fruitful the object required is gained. If we have a poor worn-out plantation, plant a new one by all means; on the other hand, by no means make a new one if the old plants are doing fairly well, unless you do not object to be without fruit for a few years. I could hardly persuade myself that any practical gardener would advocate a practice of removing canes annually, biennially, or at any stated period, for a more precarious practice no one could follow. A fact or two bearing on this subject will not be out of place. I will simply record them and leave them to speak for themselves.

For more years than anyone seems to know a fine plantation of Raspberries had grown here. In order to have all the fruit in one quarter the young canes were moved to that quarter. That was five or six years since. The result has been such a scarcity of fruit that has not been known for I daresay thirty or forty years. The first planting was made under the care of that good gardener, as well as good soldier and gentleman, the first Lord Hill. I have been working away at the new quarter of canes for four years, and have only now brought them into a good bearing condition. I may state that the ground, in which they were planted is naturally unsuitable for Raspberries.

I have yet another case to record. Three years since I planted good canes in good soil, and they are only now just coming into good bearing condition—I mean bearing in such a manner that it will pay to cover them with nets to protect the fruit from birds.

I will note one other instance relating to this subject. I know of a plantation of Raspberries in a gentleman's garden in Devonshire. Everything was done that could be done to produce really good canes and crops. Canes planted three or four years produced little or no fruit. The gardener came to the conclusion that they were planted too far apart, and had others planted between them, and the same year that these new canes were planted between the others the older rows produced a very fine crop. The gardener decided that it was really by planting between that had induced the others to bear. How little could that man have known of the character of Raspberry canes! It was simply that the first-planted canes had become thoroughly established, and then they bore well; but, mind, it took four years to do this. I must have a word or two more on this subject in answer to "WILTSHIRE RECTOR'S" observations.—JOHN TAYLOR, *Hardwicke Grange*.

JUDGING ROSES.

I HAVE been much interested in the discussion which has now been carried on for some weeks in the Journal on the subject of judging Roses, and intended to write on the subject some time ago, yet the time passed by without my doing so; and now I consider that my friend "WYLD SAVAGE" in his letter of March 28th has, as it were, challenged me to give my opinion and back him up in his preference to form *versus* size.

I quite see and follow Mr. Pochin's remark "that this might have been that, but that can never be this," and I also say without fear of contradiction that he is about the best judge of a Rose in England; but with all due deference to his judgment I think form is before size. I mean to say that if I were judging at eleven o'clock and had to decide on the merits of two Roses, the one larger, which had been at its best at half-past ten, the other smaller, rather more perfect in form, and would be at its best say at 11.30, I should decide in favour of the latter, for I believe that the moment a Rose is past its best in the matter of perfection of form and brilliancy of colour, although it may increase in size, it is worthless in a box of show Roses; but when you have equal form, equally well-shaped petals, equal colour and foliage, no judge could or would hesitate for a moment in giving the palm to the box with the largest blooms. I therefore agree with "WYLD SAVAGE" in his order of points:—1st, form; 2nd, colour and freshness; 3rd, substance and good foliage; 4th, size. In my opinion size in a Rose is one of the most difficult points to judge, as two blooms of the same Rose (take for instance, Etienne Levet) exactly the same size may be very different if one is cut from a cutback and the other from a maiden plant. One is full of "stuff," if I may so express myself, whilst the other is thinner in petal, and, to attain the same size as the one cut from the maiden, must be a little older in growth. I mean by this that one loses form, though perhaps only in the slightest degree, to attain size, whilst the other has size and form combined, and when like this size of course is a most important point.

I regret as much as Mr. W. Wilson Saunders does that so many Roses are now raised without scent; but it would be hardly possible to disqualify a Rose otherwise perfect in form on account of its lacking scent.

Now as to the respective merits of Teas and Hybrid Perpetuals shown together in the same box; though passionately devoted to Teas I cannot see with justice that they ought to have an extra point simply because they are Teas. The argument in their favour of the difficulty in growing them cannot be entertained, as they are much easier to grow to perfection than such Roses as Marquise de Mortemart, Madame Furtado, and a few other Hybrid Perpetuals; but I do think that many judges would be influenced by a few Teas judiciously interspersed if in themselves they were equal to the Hybrid Perpetuals in the same box, because such colours as Maréchal Niel, Souvenir d'un Ami, Souvenir d'Elise, Cloth of Gold, *cum multis aliis*, relieve in a most wonderful manner the too (frequently unavoidable) great monotony in the various shades of reds and pinks; and here Mr. Cant of Colchester gives the soundest advice, and with which advice I most cordially agree, "that it is of the highest importance when staging a box of Roses to have a variety of colour."

I see that it is the opinion of some of your correspondents that judges should take into consideration the distance Roses have travelled, and make an allowance for those cut the day before which are shown against those freshly gathered. Would

that this could be done, as I believe that the Herefordshire Rose-growers are longer on their journey and have more difficulties to contend against in the transit of their Roses than any others who show at the London exhibitions. But this can never be. Roses must be judged on their own merits without any allowance whatsoever at the time the judges too often find them opening their eyes and peeping at them; and, as Mr. Baker says, "Let the best Roses win."

I think with the majority of your writers that some rules should be drawn up by the National Rose Society, for surely they would be a guidance to some judges, who, when asked to judge at country shows, honestly confess that they do not consider themselves equal to judging Roses, but in default of anyone present better will do their best; and my experience is that they do as a rule judge most conscientiously, but frequently on wrong premises, thinking that a lovely truly grown Rose like the Duke of Wellington or Comtesse Cécile de Chabillant cannot possibly have a chance against a gigantic Paul Neyron, and most frequently go in for size without any regard to quality.

I also think three judges ought in every class to be appointed, and, further than this, that they ought to be chosen from different points of the compass, so that in every case there would be three *ex parte* judgments.—THOMAS JOWITT.

P.S.—Since writing the above I have read Mr. Pochin's letter of April 11th, and I hope that neither he nor anyone else will think by my letter that I advocate small blooms: nothing of the sort, the larger the better, but a smaller bloom with form in preference to any bloom however big without form. I therefore put size last, because I think if size is insisted upon as the *ne plus ultra* many judges may be apt to give prizes for Roses which have size and size only to recommend them, with flat centres too often, and in other respects not equal in my idea to a much smaller Rose with a grand high centre and fine colouring. Mr. Pochin also gives me the credit of showing magnificent blooms, and I believe—though perhaps it is only my vanity which makes me think this—that I can grow Roses as large as anyone; he will therefore know that I do not advocate small blooms because Grapes are sour. But I have in more than one instance seen prizes given to Roses on account of size though all the bloom was off them; and I myself was told once pretty plainly of my bad judgment when my co-judges with myself were unanimous in giving the award to smaller but much fresher blooms, whilst the unsuccessful exhibitor, or rather his foreman, raved about the size of his washed-out blooms.

I DO not at all feel inclined to throw up the sponge in this controversy, nor indeed do I think I have done so, as my friend Mr. Pochin suggests (for even though we differ in an important point I hope I may still consider him a friend); but I hope to show him that he entirely begs the question so far as I am concerned.

Mr. Pochin (*vide* his article in the Journal) puts size first. I put form first. But this by no means proves that I underrate the value of size, still less does it show that I place medium-sized Roses before large Roses. What I say, and what my articles have over and over again stated is, that it is better to have medium-sized blooms of good form and freshness than large coarse overblown blooms.

If you have form and size combined then undoubtedly you have the finest blooms. Mr. Peach is quite right. I struggle, as do all of us, to get large blooms, but not to sacrifice form at the cost of size.

Mr. Jowitt's blooms at St. James's Hall were conspicuous for both form and size, so that undoubtedly they were the best Roses that could be brought; but if they had had merely size without form the result would not have been the same, as I am confident that Mr. George Paul and Mr. Cant, two of the judges on that occasion, would have given the first prize to Mr. Baker.—WYLD SAVAGE.

NATIONAL CARNATION AND PICOTEE SOCIETY.

THE arrangements have now been completed for the next southern Exhibition of this Society. It will be held at the Royal Horticultural Society's gardens on Tuesday July 16th, a date which will most probably, if we have anything of a fine season, suit the growers of the flower in the south of England. The long-continued illness of Mr. Dodwell, which all lovers of his favourite flowers must regret, has not enabled him to take so active a part in it as last year, and therefore it is the more

incumbent on all who take an interest in these flowers to put their shoulders to the wheel and ensure a successful exhibition. It must be remembered that it is entirely dependant on the subscriptions of its members, as there is no gate money to be received, so that unless these are liberal the prize list cannot be so liberal as the Committee would wish.—D., Deal.

PERPLEXITIES.

I WAS once in a bookseller's shop obtaining a monthly part of a book on garden management. There chanced to be in at the same time an old gardener who did not hesitate to speak disparagingly both of books on gardening generally and of those who read them. As I was very young and inexperienced I did not venture to gainsay him; and yet, although in the main he was wrong, I am afraid he had at least some slight justification for saying "There has been more nonsense written about gardening than any other business going." These are not my words, and they do not exactly express my meaning; but in reading we do meet with contradictions in instructions that prevent us denouncing the old gardener referred to too harshly.

I can only quote one or two cases in point at present. Here is one: In giving directions for planting fruit trees the following occurs—"The stations being prepared and the trees having arrived, it is necessary to prune the roots by taking off all the small fibres and shortening the larger roots to about 6 inches from the stem. . . . Two or three spurs are sufficient, but if there be more good ones they may remain after being carefully pruned." I am not prepared to cite any authority in opposition to this, but I should like to know, where these instructions have been carried out, what the results have been.

Again, in a catalogue issued by an eminent firm last autumn, in remarks on the cultivation of Hyacinths I find the following—"Use the soil in the crude rough state, pressing the pot quite full and firmly; then add a dash of gritty matter to the surface, taking each bulb firmly in hand and pressing it down by force into its bed, making the soil firm all round and finishing off quite level." I have certainly seen that system condemned, but cannot recollect when and where just now; but in my own practice I once potted Hyacinths on that principle, "pressing them down into the soil," and when I brought them from seclusion they were each one elevated on a quantity of white stilts as if on a journey to fresh quarters.

I now turn to another subject—namely, the pruning of Gooseberry trees. Your able contributor "A KITCHEN GARDENER" says in our Journal of December 27th last, "When the bushes have attained their full size cut the young wood close in to the old stems annually." I expressed my opinion on this subject some time since, and it is not necessary to repeat it, but I will quote editorial opinion in answer to a correspondent on August 31st, 1876—"Bushes 6 feet through and touching each other may, if the growth is crowded, be thinned, &c., bearing in mind that the fruit of Gooseberries and Black Currants will be mostly produced on the young wood."

I have no doubt hundreds look over our Journal and kindred publications for information, and when an amateur finds such evident contradictions must he not feel somewhat bewildered? Not for one moment would I condemn the practice of freely expressing our opinions on different subjects and detailing the means by which we may have met with some measure of success, but I think the dogmatic manner in which some "lay down the law," as if that and that only was the way in which a certain operation can be performed tends to the forming of opinions similar to those of my old friend mentioned at the beginning of this communication.—J. J., Lancashire.

["A KITCHEN GARDENER'S" article read in its entirety represents sound practice; the "answer" quoted is also correct. The "contradiction" discovered is more apparent than real.—Eds.]

RICHARDSON'S HOODED TUBULAR BOILER.

IF all the new Peas that had been introduced within our memory had fulfilled the conditions claimed for them of each new variety being a week earlier than the earliest sorts then existing, we should have green Peas in March instead of having to wait until May and June. So with boilers. If every new boiler had possessed to the full all the advantages claimed for it our garden structures would now be heated for next to nothing. A few years ago the horticultural world was startled by the announcement that that desideratum had been actually

accomplished. We were not caught with the chaff that was scattered so freely anent the lime-heating innovation, and we have the satisfaction of not having published anything relating thereto that led to great expenditure and proportionate disappointment. The heating of garden structures cannot be reduced to nothing, but by the skill and ingenuity of hot-water engineers boilers are produced that reduce the cost of heating to a minimum. One more addition to the many excellent boilers in operation is introduced by the well-known respectable Darlington firm of W. Richardson & Co. This boiler, as

Fig. 42.

may be seen by reference to the accompanying figures, is constructed on sound principles, and we shall be much surprised if it does not prove quick in its action and powerful. Not only does the flame encircle every part of the boiler, but a great

Fig. 43.

portion of the heat acts directly and immediately on the inner surfaces of the boiler, which is a point of very great importance. The boiler is a combination of the tubular and saddle, and the alliance of the two systems is effected in such a satisfactory manner that renders the apparatus worthy of the notice of horticulturists.

But while the form of a boiler exerts much influence in the economical extraction and diffusion of heat, it must not be forgotten that the nature of fuel exerts a corresponding influence. A very ordinary boiler with good fuel is equal in heating results to one superior in point of arrangement and construction but served with fuel of an inferior character. This point is sometimes forgotten when the merits of boilers are estimated under necessarily varying conditions. Another point also of great moment is the arrangement of the pipes in connection with a boiler. We have known boilers condemned through no fault of their own. The best boiler ever devised may be rendered inoperative by the faulty arrangement of the pipes. These are matters that must never be left out of consideration in estimating the relative merits of boilers.

We think the apparatus figured possesses real merit, and it is submitted for comparison with other boilers which may be found in previous issues of this Journal.

ESCALLONIA MACRANTHA.

OF all the shrubs that cheer the winter and early spring months I know of none to take precedence of the *Escallonia macrantha*; its dark green foliage beautifully intermixed with an abundance of bright rose-coloured blossoms gives it a very cheerful appearance, and especially when anything like a flowering plant is a rarity in the open air. In my opinion this noble shrub deserves a prominent position in every shrubbery. It will also bear comparison with any other shrub planted in the grass as a single specimen. Having in charge several beautiful specimens of the above, I will give the dimensions of two of the more noteworthy amongst them. No. 1 is 10 feet high, 17 feet in diameter, and 51 feet in circumference;

it is close and compact being dressed once a year with the clipping shears. No. 2, *Escallonia macrantha rosea*, is 13 feet high, 19 feet in diameter, and 62 feet in circumference. This plant is allowed to grow at will and wears a most flourishing appearance.—ANDREW CAMPBELL, *Muckross Gardens*.

AN EXTRAORDINARY ROSE.

"WYLD SAVAGE" gives an account of an extraordinary Marie Baumann shown by Mr. Baker, and asks if anyone can give a similar instance. I think I can give an account of a still more wonderful Rose. The Exeter Show in 1876 was on Friday June 23rd. On Thursday morning the 22nd I cut a bloom of America from a maiden shoot (Briar) at five o'clock A.M., and took it with other Roses to Exeter by the eight o'clock train that evening, staging it amongst my other Teas, with which I had a great fight with "Hercules" for Mr. Paul's pretty cup which he so kindly gave for twelve best Teas. I came in second. "WYLD SAVAGE" mentions this Rose in your Journal of the 29th.

I gave all my Roses to an old friend, who carried them off and put them in a vase. At the same time Mr. Baker carried me off to his hospitable house; and I can truly say that if he starves his Roses—and they say he does—in the same way that his good lady starves her guests he need not fear winning every first prize in England. The next day I lunched at the house to which my Roses had been taken; and in the afternoon, seeing America looking most beautiful, I begged it back again. I put it in my small Tea box and took it home under the seat of the carriage—not a very cool place, and on arriving home at eleven o'clock P.M. placed it in my cellar. There it remained Sunday, Monday, and Tuesday. On Tuesday evening at seven o'clock I packed it again and took it with others by the eight o'clock train to London, arriving there at five o'clock in the morning, crossed from Paddington to Victoria in a "growler," and travelled down to Maidstone on one of the hottest mornings I ever remember, showing it in a box of Teas with which I won a prize. This Rose was therefore gathered on Thursday morning at five A.M., had at least twenty-five hours' railway travelling, was shown at two shows as far apart nearly as possible, and was in existence from Thursday morning until the next Wednesday evening.—THOS. JOWITT.

ROYAL HORTICULTURAL SOCIETY.

APRIL 16TH.

FLORAL COMMITTEE.—Dr. Denny in the chair. We have to notice one of the most attractive exhibitions that has been arranged in the conservatory for a long time past. The groups arranged by the several exhibitors contained many rare and choice plants, and there was something in every collection that merited close examination.

Taking the groups in their order of arrangement, we come first to an unique collection of Orchids from Sir Trevor Lawrence, Bart., Burford Lodge, Reigate. Every plant in the group was worthy of notice. *Cypripedium calceolatum*, with sixteen fine flowers, had a remarkable effect by the long pendent tails drooping even below the bottom of the pot; some smaller specimens of the same Orchid had extremely fine flowers. *Tricopillias lepidia*, coccinea, and *suavis* were in admirable condition, and *Cymbidium eburneum* was represented by grand flowers. *Saccolabium ampullaceum*, *Lycaste Skinneri* *Rubella*, various *Odontoglossa* including O. Hallii, O. Alexandræ, O. cirrhosum, O. Roezlii, and O. gloriosum, *Masdevallia Harryana*, *Dendrobium cariniferum*, *Cattleya citrina*, and *Lælia cinnabarina* were all in excellent condition. Besides the Orchids *Spirea palmata elegans* and a good plant of *Griffinia ornata* were noticeable; and not less so was *Freesia Leichtliniana*, which diffused its powerful perfume, and its primrose-coloured *Ixia*-like flowers were extremely attractive. A gold Banksian medal was awarded for this collection.

Messrs. Rollisson & Sons, Tooting, exhibited a large and very fine group in which admirably bloomed *Azaleas* predominated. These were low standard plants, having heads 2 to 3 feet in diameter. Very striking were *Rachel Von Varnhagen*, pink; *Charles Leirens*, double scarlet; Mr. Wright, white flaked rose; and *Punctulata*, scarlet and white, some of the flowers being self-coloured, and others striped and spotted. The central plant in this group was a grand example of *Arpophyllum spicatum*, with upwards of thirty spikes; new *Dracenas Baptistii* and *Berkleyi* being very highly coloured; *Erica tubæformis*, very rich; *Boronia*, *Genistas*, and *Palms* completed the group, for which a gold Banksian medal was awarded. The adjoining collection was arranged by Messrs. Cutbush & Son, Highgate, and was composed of admirably bloomed *Rhododendrons* in good varieties; *Azaleas*, *Cordylines*, *Palms*, and the rich old greenhouse plant *Hovea Celsii*. A silver-gilt medal was voted for the group.

We next arrive at an extensive, varied, and remarkably fine contribution from Messrs. Veitch. It was difficult to know which to admire most, the forced hardy shrubs—*Rhododendrons*, scarlet and double white *Thorns*, *Laburnums*, hardy *Azaleas*, &c.—the gorgeous group of *Clematises*, the plants being in 7 and 8-inch pots, or the fine bank of *Roses*. The blooms on these plants (*Roses*) were not only extremely fine but were remarkable for their high colour. In the latter respect we never saw *Roses* to surpass if equal them at this period of the year. Amongst the dark varieties *Beauty of Waltham*, *Felix Genero*, and *Annie Laxton* were very fine; and as a light *Rose* *Duchesse de Valombrosa* was conspicuous by its excellence. The *Teas*—*Rubens*, *Souvenir d'un Ami*, and *Madame de St. Joseph*—were in admirable condition. Amongst the *Clematises* *Sir Garnet Wolseley* was perhaps the finest of the dark varieties. *Albert Victor* was also excellent, as indeed was *Lady Londesborough*, silvery lilac; and *Miss Bateman* was the best of the whites. It is impossible to overestimate the value of such plants as these and *Roses* for conservatory decoration at this season of the year. Messrs. Veitch also exhibited some remarkable plants of the *Otaheite Orange* laden with fruit. These plants, which were in 6-inch pots, were only about 18 inches high, and each plant was bearing from twenty to thirty *Oranges*. The same firm also arranged some very fine *Hippeastrums*, *Junius* and *Hero* of *Plevna* were remarkable for their richness (crimson) and substance of petals. They also exhibited very good *Gloxinias* and *Ferns*, and were worthily awarded a gold Banksian medal.

Mr. Wills arranged a very large and very charming group, and one not easy to describe. The groundwork, however, was composed of *Ferns*, from which thousands of *Lily* of the *Valley* peered; dotted here and there and rising above them were small standard *Azaleas*, choice *Dracenas*, *Crotons*, &c., and several *Orchids*, the whole being shaded by the fronds of the taller *Palms*. Near the front were some excellent *Gloxinias* and baskets of *Maréchal Neil* *Roses* and *Stephanotis*, the whole being margined with *Lycopods*. *Dracenas Ernesti*, *Willisi*, *terminalis alba* and *igneas* were noticeable on account of their distinct colours being represented on such small plants. *Nidularium Meyendorffii* also commanded attention. A gold Banksian medal was voted to Mr. Wills for the artistic arrangement of the collection. Between Mr. Wills's and Mr. Aldous's collections, Mr. Walker, Thame, Oxon, exhibited a box of thirty-six *Maréchal Niel* *Roses* really magnificent. The blooms were as near perfection as we think it possible for *Roses* to be, and the Committee marked their approval of their great excellence by voting Mr. Walker a cultural commendation for them. *Gloire de Dijon* and other varieties were also good, and merited the vote of thanks awarded.

Mr. Aldous's collection was composed chiefly of such flowering plants as *Lilies*, *Cinerarias*, *Pelargoniums*, *Hydrangeas*, *Spiræas*, *Heaths*, &c., interspersed with *Palms* and *Ferns*. A silver medal was awarded.

Mr. B. S. Williams's group was an extensive one, and was gorgeous by the many *Amaryllises* that it contained. All the varieties of these were good, the finest, perhaps, being *Oriental*, scarlet, large and of excellent form. Amongst the *Orchids* were *Dendrobium Falconeri*, a fine variety; *Wardianum*, *crassinode*, *Pierardi*, and *Schroederi*; *Cattleya Mendeli*, excellent; *Masdevallia ignea* and *Aërides Fieldingii*, very fine. *Dracenas Berkleyi*, *Renardiae*, *Mrs. Bause*, and *Scottiae* were in excellent colour; they are undoubtedly valuable varieties. *Psychotria leucantha*, a dwarf plant with large *Magnolia*-like foliage and a terminal head of waxy white flowers, was noticeable in the collection, as were also *Sarracénias* and grand pyramids of *Azalea amœna*. A gold Banksian medal was awarded. First-class certificates were further granted to Mr. Williams for a new *Palm*, *Wallichia zebrina*. This is highly distinct on account of the zebra-like markings of the long leafstalks, which support alternately arranged leaflets 8 inches long and 8 broad at the base, glossy and bright green; also for *Amaryllis E. Pilgrim*, flower medium-sized, petals well formed and of great substance; colour clear glowing scarlet with a white stripe down each segment. A variety of undoubted merit.

Mr. Bull exhibited a few very choice plants. First-class certificates were awarded to *Davallia filijensis*, a *Fern* of chaste elegance; and for *Adiantum tetraphyllum gracile*, a low-growing highly distinct plant from South America. The young fronds are bronzy pink in colour, and are very glossy and attractive; distinct and good. A botanical certificate was awarded to *Allocasia Johnstonii*, the leaves being sagittate and stems jointed. A vote of thanks was further awarded to the same exhibitor for *Lastrea cristata variegata*, a distinct and attractive *Fern* from Japan. Mr. Bull also exhibited a cone, resembling a gigantic *Pine Apple*, of *Encephalartos lanuginosus*, which had been produced by a plant from Mr. Bull's establishment, and grown by Mr. Tillett of Norwich. The weight of the cone was 204 lbs. At each end of the conservatory Messrs. Barr & Sugden had arranged imposing groups of *Daffodils*. The great variety represented in these groups, which combined in a remarkable degree brilliancy with chasteness, warranted the Committee in voting a gold Banksian medal for them. Besides the honours above recorded first-class certificates were awarded to Messrs. W. Rollisson & Sons for

Grevillea robusta var. *filicifolia*, a stately plant with drooping foliage of great elegance, a valuable acquisition to decorative plants; to Mr. Green, gardener to Sir G. Macleay for *Dietes Huttoni*, a small Iris-like plant, yellow striped with maroon, very distinct; to Messrs. Veitch for *Crinum bracteatum*; to Mr. R. Parker for *Caltha palustris* fl.-pl. minor, very dwarf, double, and floriferous; and to the same exhibitor for *Megasia purpurascens*, very distinct, colour purplish crimson, a fine plant for pots or borders.

Votes of thanks were awarded to Mr. Mills, gardener to Lord Rendlesham, for cut blooms of *Cattleya Skinneri*; to Mr. J. Scott for cut blooms of *Maréchal Niel* Roses; to Mr. Dean for hardy spring flowers; to Mr. G. F. Wilson for new seedling *Primrose Alice Wilson*, distinct; to Mr. Green, gardener to Sir G. Macleay, for terrestrial Orchids in flower; to the Hon. and Rev. T. J. Boscawen for *Amaryllis Beauty of Cornwall*; to Mr. Hooper, Bath, for *Pansies*, fine flowers and rich colours; to Mr. Ambler, gardener to Mrs. Jennings, for a basket of Alpine *Primulas*; to Mr. Bull for *Odontoglossums*; to Messrs. Lane & Son for a very fine collection of cut Roses; and to Messrs. F. & A. Smith, Dulwich, for *Cinerarias*, the pips being exhibited in sand and representing very fine varieties.

A group of *Azaleas* and a collection of border Alpine *Auriculas* were sent from the Society's Gardens at Chiswick. They were very attractive.

The FRUIT COMMITTEE had scarcely any duties to perform. Mr. Wildsmith, Heckfield, sent an excellent dish of *Vioomtesse Hérisart* de Thury Strawberries; and Mr. Woodbridge, Syon House, sent very fine heads of the Purple Seakale, to both of which the thanks of the Committee were awarded.

Altogether the Exhibition was a superior one, and it was unfortunate that the weather was such as to prevent the attendance of many visitors. In the morning rain fell freely, and in the afternoon a mist settled over the metropolis which rendered the day one of the most gloomy of the season.

During the afternoon Mr. Jennings, the Assistant Secretary, read an interesting paper on the International Exhibition recently held at Ghent.

Mr. Jennings' lecture gave rise to a discussion as to the advisability of holding a great international horticultural exhibition in England. Several horticulturists present having spoken strongly in support of such a gathering, Lord Alfred Churchill stated that the Council would meet to consider the best means of complying with the wishes expressed; indeed, Mr. Haughton stated that the Council had already been in communication with their landlords, the Commissioners for the Exhibition of 1861, on the subject referred to. We emphatically support the proposition so opportunely made, and trust that every effort will be made to carry it out successfully.

NOVELTIES IN THE ROYAL GARDENS, KEW.

Of high classic interest is the common Daffodil "that comes before the swallow dares, and takes the winds of March with beauty;" and although the forms we have to mention were unknown to the poets, yet still they no less deserve their praises sung. Before us we have magnificent flowers of the garden varieties *Emperor* and *Empress*, by which we are tempted to mention first of all in our notes those of their rarer allies now to be seen in the herbaceous ground. *Narcissus Graellsii* is a yellowish white and charming form of *N. Bulbocodium*. *N. apodanthes*, otherwise *N. rupicola*, is a scarce and extremely pretty form of *N. juncifolius* with a deeply lobed corona and slightly glaucous leaves. *N. triandrus* is very distinct and charming; the perianth is lemon yellow, and so sharply reflexed as to possess an appearance and character quite its own in the *Mediocoronatæ* to which it belongs. Its cup is paler in colour and has an inflated appearance by the narrowing of the mouth. *N. poculiformis* has been known in gardens for the last two centuries, and being unknown in a wild state is considered a hybrid. It has creamy white flowers deliciously scented, and in gardens is often known as *N. montanus*. Just on the opposite side of the walk is a well-established plant of *Bongardia Ranwolffii*. It is extremely rare, and has here flourished a considerable time under a handlight. The flowers are the size of a sixpence, bright golden yellow, and in considerable number. Every leaflet has a dark zone much as in some Clovers, by which it has an unique appearance. *Iris sambucina aurea*, to which we have before drawn attention, is now in its best appearances. The leaves are entirely yellow, and we know of nothing similar in the genus. It originated at Kew, and has now attained the size of a respectable clump.

In the Cape house of the new range we are first brought to a stand by *Sonchus platylepis*, a Sowthistle it is true, yet we can say confidently the choicest and best of the genus. It

bears about the same relation to the common Sowthistle as *Senecio pulcher* to Groundsel. The flowers of this, however, are bright yellow, and each flower head measures $2\frac{1}{2}$ inches across, of which about six compose the inflorescence. This is terminal and arises from a basin of pinnatifid leaves which alone form an ornamental feature. It is a striking phenomenon that herbaceous orders and genera of the Continents are represented frequently in the island floras of St. Helena and the Canaries by arboreal species. So this, a native of the Canaries, is possessed of a woody stem and shows no attempt at subterranean extension. In a wild state it is rare, and this possibly is the only plant under cultivation. Near this is a strange and rare *Pelargonium*, *P. Bowkeri*, from the Trans-Kei country of South Africa. It has peculiar red-brown flowers; the petals are cut into a fringe in a manner that no equal can be found in the genus; and the leaves, which first are pinnately divided, are further cut into thread-like divisions. This is probably the only specimen in cultivation. *Amphicome Emodi*, but for its cultivation here and in one or two other places, might be numbered among the good old greenhouse plants lost to the culture of recent years. The branches spread near the soil, and the leaves form a pretty tuft almost like Burnet, between which arise erect racemes of pink trumpet-shaped flowers with yellow throat. It came from the north of India, and was introduced about twenty-six years ago. *Speirantha convallarioides*, which is sufficiently described by its name as regards foliage, was figured first in the "Bot. Mag." as *Albuca Gardeni*, but to this genus it evidently does not belong. The flowers are pure white and star-like, in erect racemes equal in height to the leaves. It is rather of botanical than decorative interest. *Pentlandia miniata* is a charming Peruvian *Amaryllid* with crimson tubular flowers an inch long.

Vitis macropus, that most remarkable of all Vines, is just about to flower in the Succulent house. It has a thick gouty stem, from which the skin peels off in lamella as from the Birch. The stems are not ripened their entire length, but with the exception of a short portion are disarticulated and cast off at the end of the season, as are the leaves. These are composed of three or five very thick and fleshy leaflets covered with white hairs when young. The flowers are small and green, truly Vine-like in character. It comes from whence do several other vegetable wonders—notably the *Welwitschia mirabilis*—viz., Benguela and Angola of Western Tropical Africa.

The note may here be made, that the first *Welwitschias* that ever grew in this country are now growing at Kew and are likely to flourish, one indeed is known to have made roots. The leaves appear to issue from the solid stock at a constant rate of growth, always growing below and not apically. With this success it is not too much to hope that cones may yet be produced.

We have already referred to *Tydas Madame Heine* in the Begonia house as a really good winter-flowering variety, and now may say that it continues in as fine flower as ever. *Sciadocalyx digitaliflora* is next in point of beauty, and to this it adds the interest of a singular appearance. The calyx is of full size, while the corolla is yet of the smallest visible dimensions; the latter gradually grows to a much larger size than the former, and assumes a pinkish crimson colour with a mouth greenish and covered with many spots. This predevelopment of the calyx may be observed in the species of *Æschynanthus*. The calyx forms a comparatively long tube, down which you have to look to see the advancing corolla. Other noteworthy Gesnerads are *Gesnera rosea* and *G. tubiflora*, the latter an old and pure white-flowered friend of delicious perfume.

NOTES AND GLEANINGS.

THE EXTRAORDINARY RAIN which occurred in the south on the 11th inst., while it has done much damage by washing up the gravel and flowers in many gardens, has greatly benefited the shrubs and trees in the parks and gardens of London. Owing to the long term of dry weather and the unusual amount of dust in March the foliage of the shrubs had become so much encrusted with dirt as to render their appearance peculiarly unsightly. So black and dingy-looking were they that a slight shower had but little effect on them; but the nineteen hours of heavy downpouring rain has cleansed them thoroughly. The stems of trees are divested of soot, and the bark is fresher than we have seen it for a long time past; but the most marked change is noticeable in the evergreens. The

foliage of shrubs which a little more than a week ago was brown and rusty is now green and glossy, and the gold and silver variegated Hollies and Aucubas, which are so suitable for suburban gardens, are now fresh, bright, and cheerful. Great and lasting benefit cannot but result to the London trees and shrubs from the thorough cleansing they have sustained, for trees, like animals, must breathe to live.

— WE have received the schedules of the northern and southern divisions of the NATIONAL AURICULA SOCIETY, and remind those who are interested in the improvement and cultivation of these beautiful alpine flowers that the southern show will be held at the Crystal Palace on April 25th, and the northern show at the Town Hall, Manchester, on April 30th. In the case of the Crystal Palace gathering especially we think the date will prove a fortunate one—at any rate for southern growers, and we trust the Manchester meeting will be equally suitable to those who work so well to make it successful. The southern schedule provides twelve classes for Auriculas and three for Polyanthus. In the Auricula (show) classes fifty-four prizes are offered, ranging in amount from £4 to 3s., and there are nineteen prizes for Alpines, making a total of seventy-three classes. In the Polyanthus classes twelve prizes are offered. This comprehensive schedule and liberal scale of awards is sufficient evidence of the energy of the Hon. Sec., Mr. E. S. Dodwell, who has worked indefatigably in making the Auricula popular, as it deserves to be, in the south. A display of great extent and beauty is sure to be provided at Sydenham, and one worthy of attracting visitors from all parts of Britain. A still greater number of prizes are offered at the northern show, which is an "established institution," and has the honour of having the champion grower of England, the Rev. F. D. Horner, as its Hon. Sec. Both these branches merit much support and deserve to flourish.

— WE have received the schedule of the ROYAL HORTICULTURAL SOCIETY OF ABERDEEN, and find that provision is made for a summer and autumn show, at both of which silver cups are offered; but the dates of the shows and places of meeting are not announced.

— RUDGIA MACROPHYLLA, now flowering in the stove at Kew, is worthy of special attention. No more lovely plant is in flower, and we are greatly surprised that after being in the country more than eleven years it is so little known. The leaves are large and handsome, much over a foot long, and in form obovate-lanceolate, with lustrous dark green surface. The flowers are funnel-shaped, about 1½ inch long, collected together in a dense nearly spherical head more than 4 inches through. The buds and flowers, we should mention, are of the purest white. It comes from Rio de Janeiro, and evidently requires the treatment of *Medinilla*.

— ON a west wall in the gardens of J. Boustead, Esq., Wimbledon, is now blooming in its full beauty a very fine plant of *CEANOTHUS RIGIDUS*; it covers a space of nearly 24 feet by 12, and is one sheet of blue from top to bottom. It is certainly a very fine specimen, and admirably trained by Mr. Jordan, who prizes it very highly. This grand early-flowering shrub deserves more general cultivation both for the rapidity with which it covers a wall and its freeness in blooming in the early spring months.

— A COMMITTEE has recently been formed for obtaining an oil PORTRAIT OF MR. ROBERT MARNOCK, the well-known landscape gardener. The following gentlemen form the Committee:—Rev. Canon Hole, Professor Bentley, and Messrs. T. Spencer Wells, John Noble, John Waterer, George Paul, J. F. Meston, Harry Veitch, and Wm. Robinson. As it is probable that many who know Mr. Marnock and his work have not received any communication as to the intended presentation, the Committee have thought it well to announce publicly that subscriptions to the Marnock Portrait Fund will be received by the Treasurer, Mr. John Waterer, Bagshot, Surrey, or the Hon. Secretary, Mr. Wm. Robinson, 37, Southampton Street, Covent Garden, London, W.C. No further announcement will be made. The portrait will be executed by an artist of known excellence, and will be presented to Mr. Marnock himself.

— MR. W. TOMLINSON, for some time assistant forester at Belvoir Castle, has been appointed wood agent at Clumber Park, Notts, in place of the late Mr. Lister.

— MR. SCARGILL writes to us as follows:—"Respecting the ORIGIN OF THE GREEN ROSE, the old man who collects the seeds in the herbaceous ground at Kew tells me that the specimen there was brought by Sir H. Barkly from the West

Indies (Demerara he thinks), not later than 1852, and was labelled 'Sir H. Barkly's Green Rose.' He, however, added that it was taken to the West Indies by the French; and further, that Mr. Niven, Curator of Hull Botanic Gardens, could give all particulars. The specimen mentioned is now labelled 'Rosa certe,' which seems to indicate French origin."

— WITH a view to promote the CULTURE OF ASPARAGUS ON THE FRENCH SYSTEM Mr. Wm. Robinson intends giving a series of annual prizes, extending over a period of seven years. These prizes will be given in London, Edinburgh, Dublin, and the north and west of England in consecutive years. The first series of prizes will be given three years from the present planting season, and will be continued annually till 1887. The prizes will be given under the auspices of the horticultural society in each locality named. In the sixth and seventh years of the series—viz., in 1886 and 1887, the competition will be held in London, and will be open to American, French, Dutch, and all other Continental growers in addition to those in Britain. The prizes at each annual competition will be as follows: For the best hundred heads, first prize, five guineas; second, four guineas; third, three guineas; fourth, two guineas; fifth, one guinea. Extra special prizes will be added, open to all comers, in the international year's competition.

— THE RHOPALOCERA, OR BUTTERFLIES.—The position which these insects assume when at rest has clearly a reference to the comparative thickness of their bodies. The antennæ, or feelers, are generally more than half as long as the fore wings, are always more or less thickened or knobbed, and sometimes slightly hooked at the tip. In moths the antennæ are of various shapes; but even the transparent-winged Hawk Moths, and the Barnet Moths, which most resemble butterflies in this respect, have such differently shaped antennæ that this character would be alone amply sufficient to prevent their being mistaken for them. There is no European moth which has antennæ sufficiently resembling those of a butterfly to allow of its being mistaken for one. All European butterflies fly by day only, and seldom make their appearance in the morning till the sun has dried the dew off the grass. They never fly in the rain, and very little when the sun is obscured. In hot countries, on the contrary, many species, especially of dark colours, fly chiefly at dusk.—(*European Butterflies and Moths.*)

— THE value of FRUIT CROPS in the United States is estimated by the Government statistician at 140 million dollars annually, or about half the value of the Wheat crop.

GLADIOLI, ROSE JUDGING, &c.

I HAVE to thank "C. P. P." and "AN AMATEUR" for their observations on the failure of my Gladioli last season and wish I could derive any crumbs of comfort from them, but I fear I cannot. I hardly think that the climate of Yorkshire, as "C. P. P." suggests, is less favourable for them than Kent; for I am told by my friend Lord Hawke, whose own from the neighbourhood of Tadcaster have been exhibited in such grand form, that he never sees them finer anywhere than at the Show at Bishop Auckland; while I can testify that even still further north those grown by Mr. Galloway and others are of first-rate excellence. As to "AMATEUR's" suggestion that I should go back to the older varieties, a florist will hardly care to grow inferior varieties when he can get finer ones; and spikes with four or five flowers will not do now when he can have them with twelve or fourteen expanded flowers. Moreover, I do not believe that this would help me much, as the following simple fact will testify. I last season obtained from France a dozen bulbs of Meyerbeer, which has been out so many years that it can be had for thirty-five centimes, and yet of this number I lost more than one-half by disease. Now it is clear from this, I think, that neither having old varieties or imported bulbs will afford any immunity from disease. I am this year trying them in altogether fresh ground, and shall hope to report by-and-by the result.

With regard to Rose judging, I think the subject has been pretty well ventilated by this time, and nothing further perhaps requires to be said until the ideas of the National Rose Society on the subject see the light. I think Mr. Pochm has been rather hard on Mr. Camm, who, however, can well defend himself. As I have also with him made size a secondary point I would like to explain that my object was to denounce such Roses as Paul Neyron and Antoine Mouton. If you can get other Roses large without losing quality, then by all means

let us have size. My own observations were intended for this end, and I hold the same view with regard to all florists' flowers. If we can have size and quality by all means let us have them; but if not let size go by the board and quality remain, and I rather fancy that Mr. Camm means the same. I cannot agree, either, with those like Mr. Bensted, who contend that a good judge must be an exhibitor, unless, like all rules, it must have exceptions, for otherwise we should lose the services of some of our best judges. Would any Rose exhibitor like to see Mr. Peach or Mr. Wm. Paul excluded from the list of competent judges? and would the former be a bit better judge if he were to exhibit in a class or two? At any rate I hope, if all be well, that he will be amongst those who will assist at the adjudication of the National Show.

A word as to that wretch the woolly aphid. I received the other day from a well-known nursery some Alpine plants, and amongst them a plant of *Primula spectabilis*. On turning it out of the pot to place on the rockery I found the roots to be infested in a very remarkable manner by the woolly aphid. On remarking on it to the person who sent them he says it is a most troublesome pest, and that he finds it very difficult in getting in plants from so many different places to keep clear of it. It is evident, then, that although it has only lately been found on the florists' *Auricula* it has for some time infested other species, but being more hardy they have been enabled to resist it better, and now that attention has been aroused to the danger we may hope that its ravages may be stayed.—D., *Deal*.

MARÉCHAL NIEL ROSE.

THIS magnificent Rose is not so generally cultivated as it merits. In many gardens there is not a respectable-looking plant of it to be found, and in others it is not grown at all—an omission for which nothing else can compensate. When grown in pots or restricted as a dwarf or standard amongst others in the open air it has no chance of developing its true qualities, and those who only grow it in those ways may just about as well not grow it at all. To grow it in all its magnificence it must be planted out in a greenhouse or conservatory, and the branches be allowed to grow to their fullest extent. It is then that armfuls of splendid golden blooms are produced and their great loveliness is fully displayed.

There is no plant in existence that will produce such a quantity of valuable flowers as a *Maréchal Niel* Rose properly grown; and by growing it properly I do not mean that great attention must be paid to it; this it does not require. No plant under glass requires less attention, but what it does have must be of the proper kind. I think there are only two important points in the cultivation of this Rose which must have the best attention: the one is to give it plenty of nourishment at the root, and the other is to let the branches extend as much as possible, or at least convenient. A very favourable position is not necessary to its well-being. Back walls and low walls are positions where it will thrive. It may also be grown up pillars or on roofs, but here it is then liable to shade plants underneath.

The best *Maréchal Niel* Rose tree I have ever seen for its age is grown on the back wall of a Peach house here. Twelve months ago this plant had only three little branches on it about 10 inches or a foot long each. At the present time its aggregate growths are 300 feet long. Last summer it produced shoots as thick as a walking-cane and from 30 to 40 feet long. This spring these shoots emitted branches from every bud, and each of these has terminated in one, two, three, and four blooms which are just opening. This plant, which twelve months ago was only worth a few pence, is now worth pounds. It is on its roots, and was merely a sucker taken from the bottom of another plant. When it was planted two or three barrowloads of good loam, with a little lime rubbish and a large quantity of cow dung, was placed round the roots. There is no means of heating the house, and the Rose occupies a strip of wall underneath the standard Peach trees on the back wall. The trees on the trellis in front partially shade it. Ever since it was planted it has never been allowed to become dry at the root, and when it ceased growing in the autumn it was watered just the same as before with liquid manure. The lower shoots are so near the ground that many of the buds are resting on the soil. As many of the blooms will be cut with about a foot of wood and leaves attached this will be all the pruning it will receive, as the more buds that are left on the more shoots there will be emitted next spring

and the greater will be the quantity of blooms. Of course it is necessary to thin-out the shoots sometimes, but not as long as one branch does not actually rest on the top of another. The more growth there is the greater demand for support, and rich top-dressings of liquid manure must be given accordingly.

I wish I could say something more strongly in favour of this unique Rose, but the truth is it surpasses description: wherever a glass structure is erected for flower-growing *Maréchal Niel* should have a place in it.—M. M.

THE ROYAL HORTICULTURAL SHOW AT PRESTON.

ON the evening of the 9th inst. the third meeting of the Local Committee of the Royal Horticultural Society was held at the Town Hall, Preston. The special business was to receive a deputation from the Council of the Society at London. There was a very good attendance, including the Mayor (Alderman Satterthwaite), who presided, Messrs. W. F. Moore, R. Poole, Joseph Harding, T. Nevett, J. C. Ambler, W. Troughton (Manager of the Preston Nursery and Pleasure Garden Company), H. J. Elwes (a member of the London Council), S. Jennings (the recently-appointed Assistant Secretary of the Society), A. F. Barron (Superintendent of the South Kensington and the Chiswick Gardens), T. M. Shuttleworth (local Hon. Sec.), and W. H. Cowell (local Assistant Sec.).

Mr. Shuttleworth briefly introduced Mr. H. J. Elwes to the meeting, and that gentleman proceeded to explain the views of the Council on the subject of the Show to be held at Preston, stating that it would tax the resources and the energy of the Local Committee to the utmost. He was very much pleased, he said, with the beauty of the grounds at Faringdon Hall, and also with the spot selected for the Show, which would, weather permitting, be believed, be a complete success. Mr. Shuttleworth produced a lengthy list of patrons.

Mr. Elwes said a guarantee fund of £1000 had already been subscribed in London, and that more would be forthcoming if required. With the £500 already guaranteed by the Preston Nursery and Pleasure Garden Company, however, he thought a sufficient sum had been obtained. He urged upon the Committee the necessity of commencing at once to make a complete and active canvass for the purpose of providing the necessary funds for the prize money offered in the schedule and the preliminary expenses, and concluded his remarks by stating that the London Council would do all in their power to render the Show a perfect success. It was agreed that the advertising and placarding in the town and other parts of the county should be left entirely to the Local Committee, and that the advertising in the London horticultural papers should be attended to by the Council of the Society.

All details relating to the fixing of the tents were settled. One of them, it may be remarked, will be of such a size that it will cover about three-quarters of an acre. The erection of various buildings for the accommodation of the staff of clerks and other officials at the Show, the means of ingress and egress, the fixing of turnstiles, the prices to be charged for admission, and several other matters of a similar character were left to the Local Committee. After a very harmonious meeting the Committee adjourned until Monday evening next, when the system of canvassing for subscriptions will be discussed and settled. It was decided that Mr. Cowell should report to the Council in London from time to time what progress the Local Committee are making with the arrangements.

The real work of this great undertaking may therefore be said to have commenced in earnest, and we sincerely hope, indeed we do not doubt, that the most perfect success will attend the labours of the Committee. It is confidently hoped that some member of the Royal Family will be induced to honour the Show by opening it, and no effort will be spared to bring about so desirable and important an event.

GENISTA RACEMOSA.

WHEREVER sweet-scented flowers are appreciated in winter and spring this old *Genista* should be grown. It is one of the most useful greenhouse plants we possess. We have two plants of it planted out in the conservatory here. They are restricted in growth to about 4 feet in height and the same in width. We have cut large quantities of flowers from them throughout the winter, and now they are one mass of fragrant yellow flowers, many of the racemes being about a foot in length. The house in which they are growing in is over 100 feet in length, yet notwithstanding this their fragrance pervades the whole atmosphere of the house, and the odour is not sickly but delightful. The more bloom that is cut off the more there is produced. It is simply impossible to kill the plants by cutting off the flowers, and they grow so freely that no extra or particular care whatever is required to grow them to perfection.

They grow as freely in a pot as planted out, but when armfuls of flowers have to be cut from them they should be planted out. Loam, sand, and decayed manure mixed together grow them well, and they should have liberal supplies of water and liquid manure occasionally.—M. M.

CAPE HEATHS.—No. 4.

APRIL.

HAVING repotted the plants a suitable position or accommodation for them is of the next importance. Although many persons consider a separate house absolutely necessary for cultivating these plants, this is not borne out by our experience. It is true that where a sufficiently large collection is grown to

Fig. 44.—*Erica Massoni*.

fill a separate structure we should always prefer keeping the plants together, but the want of this convenience should not deter amateurs from growing some of these very beautiful plants, because Heaths thrive admirably when arranged with a miscellaneous collection of New Holland and other Cape plants.

Air and light in abundance are essential to the well-being of *Ericas*; but although enjoying a maximum of the former element they do not like sharp currents or cutting winds, more especially at this particular season of the year. We also advise the keeping of them a little closer immediately after repotting until growth commences and the roots begin to work into the new soil, after which more air may be gradually given until, later on in the season, they may be stood in the open altogether,

E. Archeriana.—A robust plant. Leaves arranged in sixes, linear, acute, furnished with hairs on the margins and deep green. Flowers produced in whorls, usually two whorls on a branch, one above the other, in shape tubular, hairy, and sticky; colour deep red.

E. cubica.—This is a dwarf-growing, much-branched little plant, possessing much beauty. Leaves usually in fours, linear, obtuse, and deep green. Flowers nearly terminal, bell-shaped, pendulous, spreading at the mouth, deep reddish purple in colour.

E. ignescens.—Leaves in fours, linear, obtuse, smooth and light green in colour. Flowers tubular, thickest at the base, with spreading mouth, produced singly or in pairs at the ends of the branches; colour reddish scarlet. A very desirable species.

E. obbata.—A grand species, which should be in every collection of greenhouse plants. Leaves in fours, reflexed, and fringed with hairs at the margins. Flowers very large, tubular, much swollen in the middle, arranged in whorls of from four to eight or more, pure waxy white, slightly streaked with red at the base.

E. hybrida.—An erect-growing softwooded species. Leaves arranged in fours, erect, linear, acute, and bright green. Flowers long and tubular, spreading at the mouth, forming long racemes of bloom of a reddish orange colour.

E. ventricosa fragrans.—This free-growing handsome plant, as its name implies, yields a grateful perfume. Leaves arranged in fours, linear, acute, hairy at the margins and shining green in colour. Flowers in dense terminal umbels, supported upon long coloured footstalks, flask-shaped, base much swollen; tube smooth, shining, bright flesh colour; segments of limb spreading, red at the base.

E. Massoni (fig. 44).—This is one of the very finest species and one of the most difficult to keep in good condition. Leaves arranged in fours, and clothed with long tomentose hairs. Flowers nearly terminal on the branches, and arranged in whorls upwards of an inch long, cylindrical, spreading, glutinous, and shining as if varnished; colour deep crimson tipped with yellowish green. The flowers are of long duration.

E. odorata (fig. 45).—A beautiful species, often known by the name of *odora rosea* on account of its grateful perfume. Leaves arranged in fours, linear, premorse at the ends, ciliated, and deep green. Flowers in umbels, campanulate, glutinous, and shining white; footstalks pink. A most desirable plant.

E. Sarileana major.—A dwarf, compact, and handsome kind. Leaves linear, flat above, channelled beneath, arranged in fours, and dark green. Flowers flask-shaped, produced singly upon long coloured peduncles, which spring from the axils of the leaves, and form dense racemes; colour shining reddish purple. It lasts a long time in full beauty.

E. vernic longiflora.—Leaves arranged in threes, obtuse, and somewhat triangular: flat above, channelled beneath, and dark green. Flowers large, flask-shaped, shining, and very sticky; colour rich golden orange, end of tube tipped with bright green.

E. tubæformis.—A fine growing hybrid, produced between *E. aristata major* and *McNabiana*. It is a free-growing plant, producing its bold flowers in great profusion. Leaves short and thick, dark green. Flowers in whorls at the ends of the branches, cylindrical tube, bright shining red, the broad expanded limb white, blotched with rose at the base.

E. perspicua nana.—A densely branched dwarf plant of great beauty; leaves arranged in fours, linear, acute, slightly hairy at the margins, and dark green; flowers produced in great profusion on all the ends of the small branches in terminal clusters, cylindrical, upwards of an inch in length; tube pinkish white, limb spreading, segments white.—W. H. G.

FRUIT PROSPECTS.

My fruit trees have been singularly lucky. I have a south wall flued through its whole length of 360 feet, of which 100 are covered with moveable frames of glass at an acute angle, but ventilated above and below. Another 150 feet are used for stove plants and Vines. The remainder is devoted to Peaches, Nectarines, and Apricots, all of which are very promising. The Apricots are already as big as Cherries. My garden wall is 15 feet high well coped with stone, and encloses an area twice the length of its breadth. On the side with a west aspect there are many Plums and some Apricots; on the exterior south wall one-half is of Apricots, the remainder Pears. The west wall is entirely in Pears on the outside, and

Pears and Plums in its interior. Now the important statement which remains is that my protection, which used to be by frigi domo or canvas, has been now supplied in all three circumstances by small tufts of Yew branches, and there has been no failure in any case. There are also other walls in an outer garden where Plum trees of the best sorts have been equally protected. My gardener thinks that perhaps the failure of fruit last year may have permitted greater vigour in the buds, but the autumn was unfavourable for ripening the wood.—G. H. VERNON, *Groce Hall, Retford.*

In Mid-Surrey no great damage has been done as yet to hardy outdoor fruit. The Apple blossom is still not out. The Plum trees do not seem touched. Some fears are entertained for the Pears, which are always more forward. Apricot and Peach bloom where unprotected is as usual lost. In respect of blossom there is very considerable promise, and if May can be weathered there is good hope of large crops. The heavy rain of April 11th followed by genial weather will do great things for all crops. March went out like a lion, but at any rate he did not threaten frosts in May.

"So many mists in March you see,
So many frosts in May will be."

—A. C.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

A NEW departure has been taken by the Royal Caledonian Horticultural Society in transferring their periodical exhibitions from the Music Hall to the Waverley Market—a change which has, in every sense of the word, proved a happy success. The Show of flowers and plants which opened on the 10th inst. was acknowledged to be the finest and most extensive ever witnessed in Scotland. Entering the Exhibition from Prince's Street by the west stair, the visitors were at once struck with the table containing the collection of fine-foliaged plants from the Lawson Nursery Company's stove and greenhouses. These comprised Palms, Dracenas, Ferns, Azaleas, Cycads, Pandanus, and Phormiums. The next table contained contributions by Messrs. Dicksons & Co. from their Pilrig nurseries. In the centre were two towering Tree Ferns, with gigantic specimens of Rhododendrons. The table also contained a numerous and excellent assortment of smaller Ferns and flowering plants. The centre table was furnished by Messrs. Downie & Laird with the most striking of their fine collection of Rhododendrons from the Royal Winter Gardens. Clinging round one of the hall columns was an Acacia laden with golden bloom, and on either flank were huge Australian Dracenas, Tree Ferns, and Rhododendrons. There were also hundreds of Hyacinths, Azaleas, Spireas, Palms, Dracenas, Narcissus, &c. The effect of the whole table was exceedingly rich. The adjoining bench contained the magnificent collection of Rhododendrons exhibited by Messrs. T. Methven & Sons, a collection which included plants from 8 feet high down to a few inches. On another table a few feet away the same firm staged a remarkable collection of Ferns. For the assortment they received the first prize. The firm also arranged a large and valuable collection of Coniferae. Messrs. Ireland & Thomson made up the greater portion of two tables with an unique collection. It included Caladiums of all the newest varieties, Orchids, embracing beautiful specimens of Dendrobiums and Phalenopsis, also Aralias, Palms, Dracenas, &c. For this table the firm received the first prize. Messrs. Drummond Brothers had a cross bench at the east end of the hall filled with ornamental-foliaged plants mixed with Orchids, Fuchsias, Azaleas, Ferns, and Hyacinths. South of this table was another cross bench, on which Mr. Robertson Munro displayed his first-prize collection of hardy spring flowers, including Primroses, Auriculas, Irises, Narcissus, &c.

In the south avenue Messrs. W. Gordon & Sons, Coltbridge, had a table one brilliant mass of flower. In the collection were some very beautiful Orchids, a handsome new seedling Primula with variegated foliage, Azaleas, Acacias, Dielytras, and flowering bulbs. The same firm likewise showed a blue-tinted seedling Cupressus Lawsoniana, which was granted a certificate. Mr. J. Anderson, Meadowbank, had a splendid show of trained Azaleas, but his speciality was his collection of Brazilian bulbs raised from seed by himself. There were at least over a score new varieties of Amaryllis. The Judges granted four first-class certificates to the choicest of the lot. A rarity in flowers was an entirely black Lily shown by Mr. Wm. Bertram, Carswell, but unfortunately its brightest days were past. Dr. Paterson, Bridge of Allan, had a small table to himself for the display of his unrivalled Orchids, which attracted general admiration.

Passing to the gardeners' classes, the most noteworthy collection was that from Millbank—Mr. J. Paterson's name appearing in the prize list more frequently than any other. It is also worthy of mention that all his awards were first with the ex-

ception of two. His collection of stove and greenhouse plants embraced splendid specimens of Anthurium Scherzerianum, a fine Tremandra ericoides (Tetratheca ericaefolia), a mass of lilac flowers, and several Ericas. His Cape Heaths, Azaleas, and Roses in pots were considered finer than had ever been seen in Scotland at this season of the year. Mr. H. Robinson, gardener, Woodlands, was perhaps the next most successful exhibitor. His collection included two fine Orchids (both Dendrobiums), Palms, and many greenhouse specimen plants admirably grown. Hyacinths were few but good. Specially commendable for size of spike and compactness of pips were Messrs. Downie & Laird's eighteen. Mr. A. Kerr's, a dozen and a half, were nearly as good; and Mr. J. Walker and Mr. W. Ellison were each first for six with fine spikes clear in colour. The cut Maréchal Niel Roses, which secured for

Fig. 45.—*Erica odorata*.

Mr. J. Jackson, Woors Abbey, the first prize, were magnificent. Mr. R. Summers' second-prize lot being more fully blown. Mr. J. Gordon, Niddrie, was first for the dozen cut Roses of other varieties, and among the more beautiful blooms were Baronne de Rothschild, Souvenir de Malmaison, and Bougère. Tulips were not so fine as we have seen nor so numerous, and the Primulas were past their best. Cinerarias and Pelargoniums were a finer display, and there was little to find fault with in the Narcissuses, Cyclamens, or Deutzias. Tree Mignonettes were well represented, and of Ferns there was a rich collection both exotic and hardy.

There was only one table of fruit, but it was, considering the season of the year, remarkable for its excellence. The Glamis Castle first-prize Grapes were large and rich-coloured, while the second-prize Grapes, Gros Colman, were large in berry and good in colour. Mr. Johnson's Pine Apple was of huge size, and his Strawberries excellent. Mr. J. Branton, Gilmerton, received a special award for a collection of fruit which embraced no fewer

than thirty varieties of Apples, three varieties of Pears, and two bunches of Grapes. The Apples were especially fine, when last year's season is remembered.

At noon the Magistrates and Town Council paid a visit to the Exhibition, and Treasurer Wilson in the unavoidable absence of the Lord Provost formally opened the Show. The Town Council, he said, had in view the accommodation of such exhibitions when they erected the Market. He thought it was patent to everybody that the Society had made a noble use of the building. Whether they looked to the variety of the plants, their number or disposition, the Show was simply unrivalled. It was the finest Show ever he saw, or that had been held in Edinburgh. The Town Council would meet the Royal Caledonian Horticultural Society liberally, and would make the rent merely nominal.—(Abridged from *The Scotsman*.)

OUR BORDER FLOWERS—CROWFOOTS.

I PASS by *Ranunculus asiaticus*, for it is not suitable for our borders. Of the Butter-flower, Buttercups, Kingcups, Gold-cups, and the "Cuckoo-buds of yellow hue" of Shakespeare we have many very beautiful varieties that inhabit our own land, making gay our meadows, hills, brooks, and hedgebanks from earliest spring to far into the autumn. Who has not seen our Goldilocks in many places during the months of April and May covering large spaces with a sheet of gold in the sunshine? Such we have in *Ranunculus auricomus*; then we have the Meadow Crowfoots and the Water Crowfoots, and who does not stay by the way to admire our floating white Crowfoot and its varieties? Then we have in the Great Spearwort, *Ranunculus lingua*, a very choice aquatic plant worthy of a place in all ornamental waters. Our Ivy-leaved Crowfoot, *Ranunculus hederaceus*, is a useful dwarf plant for moist places and rockery. In the earliest days of spring we have our Pilewort, *Ranunculus Ficaria*, offering to the Brimstone butterfly, one of our earliest visitants, a resting place. The White Crowfoot, *Ranunculus Ficaria alba*, is a telling spring bedder not half so much grown as it deserves, being useful for all places. Another of this batch, *Ficaria ranunculoides plena*, one of the choicest gems, ought to be massed in every spring garden and border.

Besides all the charmers of our own in this extensive family we have a grand importation from many other parts of the world. In *Ranunculus amplexicaulis* I see one of the most beautiful of all our border flowers. Its pretty foliage and pure white flowers are charming in the spring and early summer. It likes a moderately dry situation, but should not suffer for want of water in dry weather. Good loam and a little peat suit it well. It requires time and care to get it established. It is increased by division after flowering. Being of slender habit it requires care in cultivation.

The double varieties of our own *Ranunculuses* ought to find favour among cultivators of border flowers. Such plants as *Ranunculus gramineus flore-pleno*, *R. acris flore-pleno* (yellow Bachelor's Buttons), *R. bulbosus flore-pleno* (Bulbous Buttercups), only need to be seen to be appreciated. They are useful where cut flowers are in demand, and when well established they last many years, continuing long in bloom. Cutting away the exhausted flower stems the plants often give us a second bloom in autumn. They like a good, sound, moist loam.

Ranunculus alpestris, *montanus*, *alpinus*, and others are capital plants for the rockeries. One of the most interesting is *Ranunculus bullatus flore-pleno*. Why this plant is so little known I am not able to say. I look upon it as a very choice summer-flowering border plant. It requires time to get established, and then has a grand effect. Sandy loam suits it, and it is increased by division after flowering.

The Fair Maids of France, White Bachelor's Buttons (*Ranunculus aconitifolius*), must not be omitted. This ought to have a very prominent place in all borders, possessing as it does so many charming properties. It is good for cut flowers and for exhibition. It requires sandy loam, and well-decayed vegetable matter, and full exposure. It is increased by division after flowering.—*VERITAS*.

WORK AMONG TREES IN APRIL.

THE middle of April is perhaps the most favourable time for sowing Coniferous seeds. The practice of laying the cones upon the beds, to open and shed their seeds under the combined influence of heat and moisture, is a very slovenly one and uncertain in its results. By far the best way to extract the seeds is to place the cones upon a kiln (a hop-oast is well

adapted for this purpose), and if they are spread upon the hair about 7 or 8 inches thick, and a regular heat of not more than 110° Fahr. kept up for ten or eleven hours, they may then be removed to the thrashing floor and beaten out by the common flail.

Among the Spruce forests of the Hartz Mountains kilns are kept up by the Government, whose officers receive the cones from the men who gather them by contract. There it is estimated that one bushel of the cones will yield 1 lb. and one-fifteenth of the seed when divested of their wings.

As a guide to those sowing Coniferous seeds we may state that a sample of average quality produces under favourable circumstances of soil and climate about two-thirds of good germinating seeds: also that about a thousand seedling plants to the square yard is considered fair nursery space. The approximate number of seeds contained in 1 lb. of each of the different kinds is as follows:—Scotch Pine, 69,600; Larch, 63,900; Spruce, 61,400; Weymouth, 30,600; Austrian, 23,800; Silver Fir, 15,600; Pinaster, 11,150.

If not already planted, the seeds of the Beech, Alder, and Birch should immediately be got into the ground.

Larch seeds may be sprinkled with water for a few days before sowing. They should be lightly covered, having less than half an inch of soil over them, and they will require netting or closely watching.

Osiers for basket-making may be planted up to the first or second week in April. Choose land which abuts upon a stream, so that water may be admitted into the bottom of the open ditches or shut out at pleasure by means of a sluice. Take cuttings of 12 or 14 inches long from straight branches of two-years growth, and plant in rows of from 1½ foot to 3 feet apart, and 16 to 24 inches between the cuttings, according to the growth of the Osier. Insert the cutting about two-thirds of its length, and cut it down to the stub at the end of the first year. By the end of the third year they will attain their full strength and afterwards admit of yearly croppings. *Salix viminalis*, *S. rubra*, and *S. Forbyana* are considered good sorts for the basket-maker. The preparation of the ground for Osiers should comprise deep trenching, 24 to 30 inches, liberal manuring, and thorough cleaning.

Transplant large-sized Hollies for hedges, taking them up with a good ball. Uncover and water beds of Birch seed in dry weather; undercut roots of seedling Oak; and remove seedling Acacia, giving them ample space and liberal waterings. A. J. BURROWS (in *Journal of Forestry*).

THE AURICULA.

I CONFESS that as a beginner in the growth, though an old lover, of this truly beautiful flower I have felt some, and I think I may say no little, fear as regards success after reading the now-and-then articles from those deep in the mystery. One writer says that it is a great pity, almost a sin, to let a tyro have "good sorts," for he is almost sure to lose them, and therefore he names a few of what he terms hardy as suitable and *good enough for him*; in other words, he applies the old adage, "It is not well to cast pearls before swine." Another is horrified at heat having been applied to the culture. Then one writes, in a dolorous strain, that there is ice on the roof of his Auricula house, but he "dare not" take them into one fronting the south, and so on. After reading such remarks as those I say one feels a little tremulous as to one's success; but for my own part, the fact that there are difficulties to contend with and surmount is to me one reason why I should *try*, as we all, I think, ought to be able to say of each day that there is "something attempted, something *done*." So the true florist will not be daunted because a great floral achievement requires thought, attention, and patience.

But then comes the question, Is that superb flower the fancy Auricula after all so very difficult to grow? We know that all that is worth doing is worth doing well. It is so in everyday life. In our work, our hobbies, our pleasures, or our rest all must be thorough, or neither is satisfactory. If a man intends to grow anything let him have the *best* at *starting*, or he will only have the notion, if he succeeds, he is at best only second to others. Long, long years has the Auricula been my favourite flower. When a little boy I used to peep through the fence of my father's garden and look into frames full of well-grown plants belonging to our next neighbour. Since then I have treasured their beauty in my "heart of hearts," and now I am growing some for myself. True, I have only begun a few months, and my first plant was George Lightbody. I think I

can hear the old fancier say, "What a pity! why not try with coarser sorts?" Not at all. Have those that want most care, and then they are sure to be well looked after. George Lightbody came to me by post one morning, a kind present from the Rev. Mr. Horner. I was at one time doubtful whether I should save this small plant, but it is alive and doing well. Thanks, many thanks, to Mr. Horner, who, though almost a stranger to me, at once put me into the position of a grower as well as a lover of the (in my opinion) most artistic flower grown. I think there is more art shown in the fancy Auricula than any florist flower that I know of. It is a triumph in its way; it is indeed "a thing of beauty." I have only about twenty plants; most of them are in bloom, and "often, oh! how often" during the day I run down to the house they are in to study their truly marvellous colouring, their wonderfully dusted foliage, their beautiful form, and high condition. What I *liked* years and years ago I *love* now.

All the plants I have had are trim and healthy, strong and thriving. Is there really any great mystery, then, in their growth beyond proper attention? I think not. Let others like myself begin, *many others*. Let this long-neglected flower be once more recognised amongst florist flowers to be what it really is—the most beautiful of all. When one man succeeds surely another can. The race is not always to the swift. The National Auricula Society's Show will be held at the Crystal Palace on the 25th of this month; let those who love gardening go, and if there is but only a show like last year they will be rewarded by a sight worth seeing, and seen never to be forgotten. There they can take notes as to the sorts they would like to begin with, and once having begun will go on, each fresh season bringing them fresh delights and pleasures—*home* pleasures, and there is no place like home. I think it was Lord Brougham who said "Happy is the man that has a hobby;" I say, "Happy is he who grows Auriculas well."—HARRISON WEIR.

NOTES ON VILLA AND SUBURBAN GARDENING.

In the kitchen-garden department work will necessarily have to be delayed for a time on heavy ground in those low-lying districts that were submerged by the heavy rains of the 10th and 11th inst. When the soil is in good working order make further sowings of Peas and Broad Beans for succession. Champion of England and Veitch's Perfection Peas are not yet surpassed by any newer varieties both for productiveness and flavour. The former requires sticks of 5 to 6 feet in height, the latter only requiring them $3\frac{1}{2}$ feet. Draw the soil up on each side of those Peas already above the ground and place sticks to them. We have known sparrows eat the Peas until they are very far advanced in growth, but the birds rarely do so much damage after sticks have been placed to the rows.

Cauliflowers under handlights should be occasionally watered with liquid manure. Four or five of the strongest plants to be left under each handlight, the others being removed and planted out to succeed the protected crop. The glass covers are placed on every night for some time longer yet to forward the earliest crop as much as possible, exposing the plants by day and to all warm showers. As the plants advance in growth the handlights are raised by placing bricks under them. Sow in the open border Walcheren Cauliflower for succession, also Broccoli, Cabbages, Savoy, Brussels Sprouts, Borecole, &c. Snow's Winter White, Adams's Early White, Leamington, Wilcove, and Suttons' Late Queen are a few good Broccolis for succession. Choose a warm open border for the seed beds, and protect from birds by covering the beds with old fish nets until the seeds have vegetated. The nets should be kept off the soil by a few forked sticks or other supports inserted in the beds.

The main crop of Potatoes must be planted now without further delay. In small gardens we advise only the planting of early sorts, as late varieties are more liable to be affected by the murrain. Myatt's Ashleaf Kidney is an excellent first-crop Potato; Early Oxford and Paterson's Victoria are first-rate later table Potatoes. Of the American varieties worthy of a place in villa gardens are Early Rose and Snowflake. The former is very early, and on light soils we have had it very good in quality; it is also useful for filling up gaps. Snowflake we grew largely last year, and were so well satisfied with it that we intend growing still larger quantities this season. We prefer planting with a spade, and if the ground has not been previously manured some manure is placed in the trenches as the digging proceeds, the Potato sets placed about a foot apart in the rows and from 20 inches to 2 feet between the rows; plant strong sets.

Beet.—The Egyptian Turnip-rooted variety is very useful on account of its earliness. If sown at once it will furnish Beet for salads long before the main crop is ready for pulling. Dell's Crimson and Pine Apple Short-top are good sorts for main crop and

winter supply. They may be sown towards the end of the present month. A main sowing of Carrots may be made at the same time. Altrincham and Long Surrey are very good sorts, but on some soils they are much affected with the maggot. When such is the case frequent sowings of Early Shorthorn and James's Intermediate to pull while young is the best plan for securing a supply. Sow in drills a foot apart, mixing the seed with sand, and well rubbing it with the hand to separate it before sowing.

Onions that were sown as previously advised are now to be plainly seen in the drills; if any blanks occur make a further sowing without delay. White Spanish is the best variety for sowing now. Salads of all kinds may be sown as necessity requires, and a sowing of White Dutch or Early Six-weeks Turnip should be made for early supply. If the weather should be moist and warm very few plants run to seed.

Frames.—The wintery weather which has lately prevailed has rendered additional care necessary in the management of hotbeds by turning the linings and adding sufficient fresh stable manure for supplying the requisite heat. Regulate the growth of Cucumbers, and sow seeds of Melons for fruiting during the summer in the frames which the bedding plants now occupy. Sow seed of Vegetable Marrow and Tomatoes. Short-jointed Long White is the best Marrow for general purposes, and Hathaway's Excelsior the best Tomato. Ascertain at once if there is sufficient of small bedding plants struck for the summer; if not, there is even time yet to increase Alternantheras, Lobelias, Verbenas, Mesembryanthemums, and such-like plants that are required in large quantities. Place Geraniums, Calceolarias, and the more hardy bedding plants in cold frames or under extemporised protection preparatory to planting them out.

Conservatories should now be very gay with Rhododendrons, Azaleas, Deutzias, Richardias, Cinerarias, Spiræas, Roses, &c. All plants that have been forced should be returned to a warm house in order to make their new growths before being planted out into the reserve garden during the summer. Hyacinths and Tulips are now fast going out of bloom, and may be planted out in the open borders to ripen. Continue tying out Roses in pots in order to have even and well-balanced heads. Smoke these and herbaceous Calceolarias if aphids should appear, and prevent mildew on Roses by dusting the foliage with sulphur. Many young shoots of Roses out of doors have been killed by the severity of the weather. Clematis Jackmanii also has its young growths killed; this will probably break further back, and so will the Roses that have suffered. Those who did not prune close will do well now to cut back the shoots to dormant buds.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PERPETUAL or Spinach Beet is a useful substitute for Spinach. It may be sown now in rows 15 inches apart, and will give a supply of leaves all through the summer; but it is not in request when round Spinach is to be had, of which make sowings between the rows of Peas. Sow Salsafy, Scorzonera, and Chicory in rich light soil and open situations. In warm situations the sowing of Chicory should be deferred until early in May, as when sown early the plants are liable to run to seed. Similar remarks apply to Beet. Pine Apple, Short-top, and Nutting's Selected are fine in colour and flavour. Complete at once the planting of Potatoes. Cauliflower plants still in frames plant out; they will afford a succession to those previously planted, and if some are planted on a north border a succession of heads will be more likely to be secured.

HARDY FRUIT GARDEN.

Fig trees are not so much grown against walls as their delicious fruit merit, and in many places the trees make too long and gross growth to bear fruit satisfactorily. This frequently arises from too rich soil and a deficiency of calcareous matter. The former defect may be rectified by root-pruning, which no tree endures better than the Fig, and the other by an addition to the soil of chalk. Root-pruning, however, is only of temporary value in restricting the growth when the trees are planted in very rich soil. An amateur who grows Figs and Peaches in an adverse climate remarkably well adopts the following practice. The bottom of the border is concreted from the wall outwards to the extent of 4 feet, the border being 30 inches deep. At 8 feet from the wall a single brick wall is built without mortar, and this gives a somewhat confined space for the roots of a yard width and of the length of the wall; 6 inches of chalk or rubble is placed at the bottom for drainage, and the border is filled with turfy loam rather strong mixed with a fourth of chalk, the whole being made quite firm. The trees make short-jointed wood and commence bearing early. When the roots have passed the open brickwork into the rich soil of the border outside, which is indicated by the grosser growths, a trench is taken out outside the brickwork but close to it down to the concrete, every root being cut off. An excellent opportunity is then afforded of trenching the border, and the trees are fruitful and scarcely suffer from frost. This cutting-off the roots and trenching the border is done about every third year, and excellent vegetables are produced as well as good crops

of fruit. A good watering is given to the trees when the fruit fairly commences swelling, and is repeated as may be required during the summer. The present is a good time to plant Fig trees; if they are turned out of pots the roots should be disentangled and spread out. Brown Turkey and White Marseilles are good bearers, having large richly flavoured fruit. Brunswick is excellent, but requires space; Negro Largo is the best of recent introductions, a great bearer, and delicious.

FLOWER GARDEN.

Pretty flowers and fresh foliage are now bursting through their winter bonds. At no season of the year does the hardy perennial, bulb, and Alpine garden yield so much interest as at present. The planting of all hardy perennials may yet be done, choosing dull weather for the operation. Propagation by division may still be practised, watering, and if needed shading the plants until they are established. Any half-hardy herbaceous plants wintered under glass or otherwise protected should now be planted out. The hardy fernery has peculiar attractions during the early summer months; the young fronds of the Ferns vie with each other in their tints of green and in displaying their elegant forms. No garden of any pretensions is complete without Ferns and Alpine plants, which cannot be cultivated so as to look well except in a suitable position by themselves. The old fronds of Ferns should be cleared away if not already done, and a top-dressing of peat and loam or leaf soil should be applied to the roots. Some hardy ferneries lack plants with bold foliage. *Cytisium falcatum* and *Woodwardia radicans* are very striking, also *Onoclea sensibilis*, *Struthiopteris germanica*, &c. *Daphne Cneorum* should not be absent from rockwork, its fragrance is always appreciated. The margins of walks and open spots in shrubberies should be occupied with Violets, Primroses, Anemones, blue, white, and pink Harebells, Orchises, with bulbs of various kinds, particularly Narcissi; Forget-me-nots, and other plants delighting in shade. Push forward the planting of evergreen shrubs, so as to have it completed before much growth is made. The holes to receive the plants should be prepared before lifting, so that the shrubs are moved with as little exposure of their roots as possible to the drying influence of the atmosphere. Water copiously if the ball becomes dried or the soil employed in filling up be dry. Stake the shrubs securely, and place a mulch of half-decayed litter or partially decayed leaf soil over their roots to prevent evaporation.

FRUIT HOUSES.

Vines.—In the earliest house red spider (especially if hard forcing has been practised), may be expected. Upon its first appearance paint the return hot-water pipes with sulphur mixed with milk so as to form a thick paint. Give the border a thorough watering, mulching afterwards. This refers to the inside borders. The water should be applied early in the day, so that surplus moisture may pass off before closing time. Early Grapes do not always colour well, the defect arising often from hard forcing, and only avoidable by a constant supply of dry warm air and a moderately low night temperature. Where Grapes are fully ripe a reduction in temperature is advisable, yet a moderate moisture should be maintained for the benefit of the foliage: the moisture will not do the Grapes any harm provided the air is changed by free ventilation. In succession houses attend to stopping and tying of the shoots, and thinning the bunches and berries, for so long as surplus berries remain they are taking nutriment from the Vine which would otherwise be appropriated by the intended crop. Vines in late houses will now be making good progress. Close early in the afternoon with sun heat, with a view to the employment of as little fire heat as possible. See that the borders have plenty of water. If failure is to be avoided the supplies of water must not be scanty; indeed red spider and shanking are usually the results of drought at the roots of the Vines.

Planting Vines.—This is the very best time for planting young canes. The borders, we presume, have been made some time, if not they may yet be formed. We prefer the borders partly within and partly outside, planting the Vines inside the house where practicable. Except for very early forcing we are no advocates of confining the roots to inside borders. The border, whether inside or outside or both, should be concreted at the bottom, unless it has a substratum of gravel or other porous substance; rubble 1 foot thick should be placed on the concrete, and proper drains and outlets must be provided. Three feet depth of soil is ample. Turf 3 inches thick taken off loam light rather than heavy, broken-up tolerably small, and mixed with a tenth part of old mortar rubbish, a twentieth of half-inch bones, and an admixture of charcoal in the same proportion as the lime rubbish, form a suitable compost; but well-drained and fertile garden soil will grow serviceable Grapes. The Vines, it is presumed, were cut back in early winter and have been kept in a cool house, the eyes now having grown 2 or 3 inches long. Turn them out of the pots, remove every particle of soil, carefully preserving the fibres. Spread the roots out straight and flat, the soil of the border having been brought to the required height, covering the roots to a depth of 4 to 6 inches, working the soil well among them with the hand, and giving a good watering with water at 90°, mulching with a little short litter. If the canes have not been shortened do not shorten them now, but remove

the buds from the upper portion down to whence fresh growth is desired to issue, and shorten the canes at the winter pruning. Six feet width of border will be sufficient to commence with. Sprinkle the Vines and house twice a day, but avoid forcing. A steady temperature is necessary so as to afford time for the formation of new roots; afterwards, and when they have started freely, every encouragement to growth should be given. Vines planted last year will be breaking naturally, and should be assisted by gentle fire heat in cold weather. Disbud, leaving the best shoots about 18 inches apart on both sides of the canes. Crop very lightly, one or two bunches should be a maximum. Any extra Vines planted to fruit early and afterwards be cut out, may carry a bunch on each shoot.

Peaches and Nectarines.—The weather lately has been very unfavourable for the forcing of these fruits, indeed all early forcing, rendering great care necessary in the admission of air, as sudden changes of temperature are inimical to the health of the trees and steady progressive growth of the fruit. It is better to allow the temperature to rise a few degrees higher from sun heat than to admit a sweeping current of air to pass through the house; also be very sparing of fire heat at night, for a high temperature in cold dull weather, and especially at night, is very injurious. Keep the shoots well tied down as they advance, and aim at having them thin rather than crowded, as upon the exposure of the foliage to light and air depends the development of the buds for future bearing. Extensions should be trained-in their full length, and if any of the side shoots laid-in for future bearing exceed a foot in length pinch out their points at that, stopping any laterals at the first joint. We find the most critical stage in Peach forcing is just preparatory to stoning, when the fruit, if it receive a check or the wood is not thoroughly ripened, will be cast. More fruit is being cast in the stoning process this year than we have previously experienced; this is undoubtedly due to the sunless season of last year, for though artificial heat may bring to maturity a crop in a dull season it is but a poor substitute for natural heat and light. Disbudding and thinning must be proceeded with, but do it gradually. Moisture will be had sufficiently by damping twice a day in dull weather, or syringing if the days are bright; let this, however, be done early, so as to have the foliage dry before nightfall.

Cucumbers.—Let the plants be looked over twice a week for the removal of superfluous fruit, thinning the shoots, stopping, tying, &c. Of moisture there must be no deficiency either at the roots or in the atmosphere, but both must be regulated by external influences. Syringe freely in bright weather, and give liquid manure copiously to plants in full bearing. A slight shade may be necessary when the sun is bright and powerful, especially after a continuance of dull weather. If straight fruit be wanted employ glass tubes, which are more requisite under frame than house culture. In pits and frames more moisture will be required, and the foliage may be damped on fine afternoons at closing time through a fine-rosed watering pot. Attend to earthing as required, maintaining a good bottom heat by linings of hot sweetened dung, covering the glass with mats at night. Another frame or pit should be planted to produce fruit after the first frame plants are becoming exhausted. Sow seed for a third frame if one be wanted, also seed of the Stockwood Ridge Cucumber kinds and the short prickly variety for Gherkins.

Melons.—Supports will be required for the fruit. Half-inch boards of about 7 inches square, secured to the trellis with copper wire, are suitable. They should slightly slope to prevent water lodging upon them, and be so fixed as to relieve the plants of the weight of the fruit. To prevent red spider paint the return pipes with sulphur, maintaining a good atmospheric moisture by sprinkling the house and plants twice a day except those in flower, which should have a drier atmosphere. When the fruit is set attend to the applying of atmospheric moisture, and keep the roots well supplied with water. Make a practice of going over the plants frequently for stopping, thinning, and tying the shoots. Apply fresh soil to advancing crops, giving timely attention to the linings of frames and the covering of them at nights. To secure the most benefit from sun heat admit a little air at 75°, increase it at 85°, not letting the heat exceed 90°, closing at 85°, or when the heat afterwards will not increase beyond 90°, though 95° will not do harm if there be a good moisture within the house or frame.

PLANT HOUSES.

Stove.—To keep up a succession of Gardenias young plants should be grown in comparatively small pots (7 or 8-inch pots are quite large enough), so as to introduce a few plants at a time into brisk moist heat to cause the flower buds to expand, which they do more speedily when bottom heat is afforded. Young plants produce very much finer flowers than old plants, but they must be induced to make free growth and be kept free from scale and mealy bug. Young plants of *Eucharis amazonica* may, when the plants are rootbound, be shifted into larger pots. Established plants must be very liberally supplied with water and liquid manure. The stronger this plant grows the finer and more numerous are its flowers. *Clerodendron fragrans* is as rich in colour as it is grateful in perfume, and does not require so much

room as the larger-leaved *C. fallax* and *C. Kamperferi*. A little leaf, soil added to sandy loam, grows it well, affording a light position and slight shade only, with good moisture and warmth. Amaryllises or Hippeastrums making growth keep in a light position, so as to have the foliage stout, as upon that and keeping it clean the coming season's flowering depends. Liquid manure not too strong should be given to the plants occasionally.

Palms.—These stately plants are making vigorous growth; keep them well supplied with water. The pots should be placed upon a hard bottom, as when they have the chance the plants root very freely from the pots, and this very often causes the foliage to have a sickly hue when the plants are removed. Palms of small size are the most useful of all for decorative purposes, especially *Cocos Weddelliana*, *Thrinax argentea*, *T. elegans*, *Euterpe edulis*, *Kentia gracilis*, *Hyophras indica*, *Chamaedorea Brazei*, *Augusti*, *Demonorops fissus*, *Latania rubra*, *Geonoma gracilis*, *Areca Verschaffeltii*, and *Chamaedorea graminifolia*.

Hoya bella and *H. Paxtoni* are coming into flower; keep the plants in a rather dry atmosphere, their flowers being then more enduring. Gloxinias advancing for flowering should be kept near the glass, and if removed to an intermediate house the flowers will continue longer than when placed in a close warm stove.

If provision has not been made for a supply of plants for dinner table and small decorative foliage plants generally, no time should be lost in proceeding with their propagation. Some of the most useful are *Crotons* Wiesmanni, majesticus, spirale, angustifolius, pictus, and undulatus. Shoots of 8 to 10 inches long should be chosen, and struck in a close moist and warm house, and should afterwards be grown on briskly, when useful plants will be had in a short time. *Aralias* Veitchi, reticulata, elegantissima, and leptophylla, are valuable table plants, and should be grown the same as *Crotons*. *Dracenas* of the narrow-leaved section, such as *angusta*, *albicans*, *Guilfoylei*, and others of the *D. terminalis* type, should be propagated forthwith if plants are to be had for autumn and winter decoration. Their tops are best striking readily in brisk moist heat. In striking these and similar plants it is desirable that they be kept close and warm, so that the lower leaves may be preserved. *Pandanus Veitchi* and *P. utilis*, with the *Palms* above noticed, having persistent foliage, are also very valuable for table decoration.

Orchids.—*Angulos* and *Lycastes* should now be repotted, using equal parts of fibrous peat and sphagnum with some lumps of charcoal interspersed. Good drainage is needful, and free watering at the roots. *Dendrobiums* require more water, giving it, however, with care, some having delicate roots. Avoid overpotting. Strong growers do best in pots, such as *D. nobile*, *D. Farmeri*, and *D. densiflorum*; but *D. Wardianum*, *D. Devonianum*, *B. Cambridgeanum*, *D. Parishii*, &c., do best in baskets suspended from the roof. *Oeogyne cristata* syringe frequently when starting into growth, and when fresh roots are made water is required copiously. *Cattleyas* and *Laelias* in a growing state require to be kept moist, whilst those having the growth completed should be kept in the coolest part of the house and have less moisture. *Miltonias* to have plenty of water, also *Cypripediums*. If the last-named plants are neglected in this respect the foliage and flowers suffer. Syringe the plants early in the morning and again in the afternoon, shading so as to subdue the fierce rays of the sun; ventilation is required in bright weather from about 9 A.M. to 4 P.M. In syringing avoid damping the flowers, or they become spotted and unsightly. *Odontogloss* when the flowers open should be removed to a dry house or they will spot, but keep the plants moist at the roots.

TRADE CATALOGUE RECEIVED.

J. B. A. Delenil, au haut de la Rue Paradis, Marseilles.—*Catalogue of Novelties and General Decorative Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (F. Watson).—"Flower Gardening for the Many," published at this office, will suit you. It can be had by post for 4d. in postage stamps. (K. K.).—The best book for you is the "Cottage Gardeners' Dictionary." For the nursery department we do not know of any work, except it be Brown's "Forester," published by Messrs. Blackwood, that will give you the required information.

ADDRESSES (Belgian Here).—You must refer to Kelly's Directories and the lists of Fellows of the Royal Horticultural and Botanic Societies.

AURICULAS (A. Loner of Auriculas).—The varieties are as good as are usually obtained from a packet of seed, but none of them possess merit

according to the florist's standard. The best flower is the one having a deep yellow centre and shaded maroon petals. We are unable to distinguish it, as the numbers had slipped from several of the pips. Some of the flowers with pure white centres are also attractive for border decoration; those with washy undecided colours we estimate as worthless.

FELLOWSHIP OF ROYAL HORTICULTURAL SOCIETY (An Inquirer).—Write to the Secretary, Royal Horticultural Society, South Kensington, and state your wish.

EUCALYPTUS GLOBULUS—"E.P." wishes to be informed where he can obtain plants of this tree.

CALCEOLARIA CULTURE (A Beginner).—You will find full directions in our "Garden Manual," price 1s. 6d.

VALUING CROPS (W. G. A. Market Gardener).—If your landlords have agreed to take your crops at a valuation it will be right for the Strawberry plantations to be included in the valuation.

CLERODENDRON FALCATE.—It can be purchased from the chief London nurserymen.

GARDENIA BUDS DROPPING (S. S. L.).—With your explicit letter you have enclosed some fallen buds. Had you sent us a spray also from which the buds had fallen it would have aided us still more in determining the cause of the disappointment you are experiencing. We suspect that the original cause of the evil is immatured wood; secondary causes—first, temporary dryness at the roots at some time or other (it may have occurred two months back); and second, a rather too low temperature. Under these conditions fungigating, if at all strong, would be prejudicial. Raise the temperature 5°. Shade only during very bright sun, and then slightly. Top-dress your plant with soot, making the surface of the soil quite black, and water copiously with tepid water. Syringe the plant freely at least twice a day, and maintain a moist genial atmosphere. Provided the drainage is efficient and the roots active *Gardenias* can scarcely have too much water. Suitable temperatures are 65° at night, 70° by day with fine heat, 80° to 85° with sun, closing the house with much moisture at 85°.

ROYAL FERN (Sussex).—The finest specimens of the Royal Fern, *Osmunda regalis*, grow in places not shaded by trees in the New Forest. This Fern will, however, grow well in the shade, and you may plant in positions most convenient for your own purpose.

WOOD OF THE LIRIODENDRON TULIPIFERA (W. H.).—The wood of this tree is smooth and fine-grained, very easily wrought, and not liable to split. It is used for various kinds of carving and ornamental work, and for articles of household furniture. Michaux says that the joinery and inside work of the houses in the western States of America are most frequently of this material. It has also been used for canoes, hence the Swedes in North America call it the Canoe Tree. It is not serviceable when sawn into boards on account of its expanding and contracting more than most other wood under the influence of the weather.

SIZE OF ROSE BOX (Jas. Brown).—Your box for staging six Roses should be 1 foot 3 inches long, by 1 foot 6 inches wide, 5 inches high in front, and 7 inches behind. In exhibiting three blooms we should insert each one in a sheet-tube or bottle of water, grouping them in the form of a triangle, concealing the tubes in a mound of moss, among which the flowers should nestle. Do not crowd them, but let the foliage have ample space to display its full beauty. The width and height of small boxes require to be the same as for large boxes, in order to secure uniformity in the show.

MILDEW ON ROSES (Edward Wilson).—Dust the foliage with sulphur, which should be left on it for a few days, and then washed off by syringing with clean water. Apply the sulphur again with promptitude upon the recurrence of the slightest symptoms of mildew; further, pay strict attention to regularity in watering, using liquid manure once a week, and keep the house well ventilated.

PRUNING DRUTZIA GRACILIS (Ten-year Subscriber).—Cut down the old growth as directed, leaving any strong new growth which may have started from the base of the shoots before the pruning. The object of pruning is to induce the formation of stout young shoots springing from or near the crowns for the production of next season's blossom. Do not retain the old straggling branches unless you wish to produce large specimens, then thin out the old growth and shorten the remainder to a foot in length.

STRIKING CUTTINGS OF TUBEROUS-ROOTED BEGONIAS (An Old Subscriber).—Fill a third of the cutting pot with pieces of broken pots, over which place soil consisting of equal parts of leaf, soil and silver sand, with a layer of pure sand on the surface, made level and pressed gently down about an inch below the rim of the pot. In this insert stout cuttings 2 or 3 inches in length, made in the usual fashion by trimming off one or two of the lower leaves and cutting off the bottom close under a joint. Press the sand about the cuttings, water well, and place the pot in a brisk lively temperature of 70° or 80°. Shade from the sun, and in a few days the cuttings will emit roots, and should be sufficiently forward for potting in a fortnight. Such cuttings grow so readily and freely that we are somewhat at a loss to account for your failure. It might arise from the insertion of cuttings taken from plants growing in a high temperature in cold golden soil, by exposure to cold cutting air in transit to a hotbed, by placing them in too low a temperature, or by taking the cuttings from plants growing in a much lower temperature—say 15° or 20°—than that which we advise for the cuttings. The *Aphelandra* you refer to we think can be obtained from Messrs. Veitch & Sons, Chelsea, who can probably also supply seed.

FUCHSIA SERBATIFOLIA CULTURE (A Subscriber).—Now is the time to make cuttings of this and other winter-flowering *Fuchsias*. They emit roots freely in a brisk heat, are then potted in 4-inch pots and kept in heat till well established in the soil, when they are removed to an unheated pit or garden frame for the summer, and repotted twice or thrice into larger pots as they make progress; 7 or 8-inch pots are quite large enough for the last pottings. You will then have them crowded with roots, and by giving very little water throughout September—just enough to keep the foliage from suffering—you will have plenty of flower buds springing forth in October, and the plants will continue in bloom till after Christmas. Old plants are often cut in now and turned out of the pots into open well-drained sunny borders in June, left pretty much to themselves during summer taken up and repotted in October, and brought into bloom with or soon after the young plants. These hints will probably show you why you have failed with your plants.

WINTER-FLOWERING GREENHOUSE PLANTS (Idem).—Your greenhouse may be gay throughout winter with a collection of Zonal *Geraniums* raised from cuttings inserted now. You may also have Chinese Primroses and

'Cinerarias from seed sown at once, Mignonette sown in succession from May till the end of August, and for variety Epacris, such Cape Heaths as *hyemalis* and *gracilis*; Cytisuses, Coronilla glauca, Cyclamens, Perpetual Carnations, and Solanums capicastrum, Weatherill's hybrids, and Prince of Wales. Cyclamens and Solanums sow now, and by superior culture the plants will be ornamental next winter. The other plants are not expensive and can be had from any nurseryman. Continue the syringing of your Camellias till the growth and foliage are fully perfected. Pot your Eucharis immediately, encourage free strong growth, then keep somewhat dry to throw it into bloom, and by alternate feeding and resting you may obtain two or three crops of bloom throughout the year.

SOIL FOR MELONS AND CUCUMBERS IN BOXES (*Idem*).—Two parts turfy loam, one part well-decayed dung. Cucumbers and Melons may be grown in the same house, but the process is difficult and undesirable.

SOWING MELON SEED (*J. Owen*).—To ripen fruit in a frame during August sow the seed towards the end of April; but much depends on the variety grown, heat provided, and mode of culture. We cannot give the address of our correspondent.

RHUBARB FOR FORCING (*W. P.*).—For early forcing plant the old Early Scarlet and Mitchell's Early Albert. To prevent Peas mildewing in summer mulch over the roots and water copiously.

FRUIT, &c., GROWING IN WINTER (*H. S. F.*).—The work you quote from is unworthy of notice. The directions are delusive.

MUSHROOM CHARACTERISTICS (*A Young Gardener*).—It is the *Agaricus campestris*; there are some slight variations. The true Mushroom has flesh-coloured gills, which ultimately become brown.

GLAZING WITHOUT PUTTY (*B. S.*).—It is not a patented practice. Any one may adopt it.

QUERIES UNANSWERED (*An Old Subscriber*).—We are not aware of any.

NAMES OF PLANTS (*S. M. W.*).—Cotoneaster Simonsi. (*G. H. B.*).—*Schomburgkia crispata*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF A BUTTER-MAKING DAIRY.

(Continued.)

It is a point of some consequence how far the arable portion of the farm can be made to supplement the produce of the pasture and park land. Besides Italian rye grass to which we have referred, trifolium claims our notice for early produce; but even that is scarcely ever fit to cut so soon as rye, therefore the importance of rye must not be overlooked, seeing that a good crop can be obtained and used for cow-feeding. Where the land is clean rye will not only yield a crop of six or seven tons of green fodder, but it will improve the prospect of root-cultivation, because either mangold or swedes will take better after a rye crop is taken off than after an old fallow. Rye, too, does not affect the flavour of butter injuriously. Trifolium must, however, come next not only in feeding value but in weight of produce. It is, however, more valuable on account of its weight of produce than its feeding properties for dairy cows; still it is a good supplement to the pasture grass, which should always be fed close, and we consider that the mistake commonly made by dairy farmers is that of depending upon the growth on the pastures only. We consider also that it should be made a leading point in feeding the cows in the summer and autumn months to have prepared a good succession of green fodder crops, so that at no time should they be dependant upon the pastures entirely. To make the succession complete we should be prepared with—first, Italian rye grass, then rye, next trifolium, then vetches and oats mixed, also vetches and tall rape mixed. The last-named is especially advantageous; in fact tall rape, or coleseed as it is called in the north, may be sown by itself and cut-up for feeding either by itself or in conjunction with grasses the produce of the arable land, except broad clover, which we reject as it often proves injurious, causing the cattle to be "hoven," or "blown." The time of year will then have arrived after using the above-named food when the pasture will be bare or stale. We must not, however, pass to the consideration of the question of root-feeding without an observation relating to the use of cake in addition to the grass and green fodder during summer, for we can confidently assert that it will pay to give cake, say 8 or 4 lbs. per day to each cow, either linseed cake, rape cake, or decorticated cotton cake. The green rape cake sold for feeding purposes is the best of all, because the analysis shows that the oil of rape is the counterpart of the oil found in butter. Cotton cake is the next best; and linseed cake is, perhaps, the worst adapted for the dairy cow,

because the oil from it is different from that of the other cakes, being of a more drying nature. An experienced friend of ours, however, tells us that he has succeeded well with palm-nut cake in a butter dairy.

Before leaving the question of pasture feeding we would remark that one of the advantages of supplementary food is, that the cattle can be made to feed the pastures down bare and keep them bare during the whole summer, particularly when a fresh change of ground can be found for the cows. This close feeding and not allowing the grass to run-up to seed heads is of great importance in order to prevent the baneful effect of "ergot" (figs. 46 and 47), in moist seasons of a low temperature like last summer,

Fig. 46.—Ergot on Timothy Grass (*Phleum pratense*).

Fig. 47.—Ergot on Barley Grass (*Hordeum murinum*).

which is neither more nor less than diseased seeds caused by an attack of fungus, which when eaten by the cows is liable to produce abortion, and in a most insidious way affects large numbers of animals, oftentimes without the cause being discovered. Abortion thus produced in one cow is, if not discovered in good time (and which we believe is seldom the case), will spread through a herd and cause heavy losses. There is a peculiar sympathetic effect amongst the cows in cases of abortion which renders it necessary on the first discovery of the symptoms to remove the affected animal entirely out of the way of the rest of the herd. The abortion in cows is in fact so serious, and its causes so little understood by cattlemen or even by farmers themselves, that we shall take this occasion to enlarge upon the

subject. The best way to avoid loss by "ergot" is to feed the grass so closely that no stalks can run-up to seed, and if they do in parts, to pass the scythe over the pastures and cut close all the bunches which are running to seed, also to keep all the hedges and fences close trimmed, for it is notorious that the coarse grasses growing in ditches and borders produce "ergot" in some seasons. It has sometimes been thought that the gross grass produced by the application of nitrate of soda and other artificial manures produces abortion simply because such gross grass has a purging effect on the cows; but we maintain that neither theoretically nor practically is it fair to blame the manures used, whether artificial or dung and compost. There may be, and often is, internal irritation produced by eating gross grass in the spring without any counteracting food such as bean or barley meal, but it would not necessarily produce abortion. Let us therefore look to accidental causes, such as injury received by breaking-out over fences and ditches, in going through gateways, or from blows one to another, and then one case of abortion is often the means of contributing to a serious spread in the herd by the sympathy before alluded to. It must be borne in mind that the first symptoms of abortion are much sooner detected by the animals of the herd than by those in charge of them, and the odour arising from the cow affected through sympathy extends its influence to numbers of animals before detection by the owner.

In passing to the subject of root-feeding we do not advise the use of turnips or swedes, as they always have a more or less injurious effect upon the flavour of the butter before Christmas. Later in the season after the Swedish turnips have been heaped and little yellow buds have grown on the stems, and when the stems have been cut off, we have known them used without affecting the butter. Still we prefer carrots, parsnips, mangold, or cabbages, and in feeding with either of these roots only moderate quantities should be given daily, cake or meal being given in connection with the roots after being passed through Gardener's cutter, and the cake reduced to meal. It will then attach readily to the moist fresh roots and be eaten together, and a most beneficial result will be produced and nothing wasted. The roots will not then disagree with the animals, each food correcting the other, and as it enters the stomach together the utmost benefit will be derived. We reckon that from 50 to 60 lbs. of roots and from 8 to 4 lbs. of cake per day sufficient for a cow, according to size of the animal and other circumstances, such as the proportion of hay or straw given in addition. We prefer straw to hay, because hay may contain "ergot" and cause abortion, but thrashed straw never. When the cows are receiving rich food as above stated hay is too fulsome and often clogs the stomach, causing the cows to refuse their food for many hours in succession; but clean fresh straw never has this effect. It has the advantage of filling the stomach and assisting rumination, and has nutrition as well, as shown by analysis by Dr. Voelcker. We do not give the analysis here, as that will appear probably in an article at a future time, the subject to be on "The Use and Abuse of Straw."

The management of the cows both in winter and summer requires a notice from us. In the winter months if the weather is mild and open they may run out into pastures only for a little fresh air and exercise; but this is not necessary unless there is a little grass to be picked up. The housing at night usually begins not later than the 1st of October, even in our most salubrious climates, such as the south-western and south-eastern counties; and the period of allowing the cows to lie out at night commences about the middle of May. In case there may be a good bite of grass the cows will even then do better to be housed at night and receive supplementary food as above stated, for we often have sharp white frosts at night in the early part of the month of May. Cows should never enter the pastures until there is a fair crop of grass, otherwise they often stand about leaving their droppings where it does no good, and this must be wrong when we consider that high feeding ought to assist in making the pastures more productive.

WORK ON THE HOME FARM.

The horses will still be employed in harrowing, rolling, drilling, &c., of the land for Lent corn, and the sooner it is finished now the better, for it is seldom a good malting sample of barley is produced sown after the middle of the month of April. Oats also give the heaviest sample and the best yield when sown before this period. The seeds of clover and grass we prefer to sow at the same time or immediately after the Lent corn is sown, and it is important that the seeds should not be too deeply buried; we therefore recommend that they should be sown after the ring roller, and only chain-harrowed afterwards. The next work will be preparing the land for mangold, and in case no autumn tillage was done the work must now proceed with all the dispatch possible, for we believe that, generally speaking, mangold is sown too late. The middle of April is not too early for sowing this crop. Some farmers, however, are afraid of the night frosts killing the young plants, but in our experience we have never known it done, nor do we believe that the idea should prevent early seeding, which is so desirable in order that the crop of bulbs should be ripe and fit to

store away early in the autumn. Large crops of mangold are often seriously injured at the time of taking up by the night frosts, which usually occur at the end of the month of October.

The present is a good time for sowing lucerne, whether we sow it in Lent corn or wheat land or on a fallow. We much prefer the former, for when seeded in corn, especially in the wheat, is nearly sure to take. Our plan is to sow 20 lbs. per acre of lucerne seed mixed with 4 lbs. per acre of yellow suckling, harrowed-in, then left rolled; in this way we have seen the crop very even and the produce abundant. The first year the suckling, too, fills up the space between the lucerne plants and keeps down the growth of grass and weeds, which are very often found injuring the lucerne whilst the plants are young. When lucerne is sown on a fallow it is usually drilled with the same quantity of seed without suckling or anything else in admixture. It is usual to drill the seed at about 14 inches between the drills, and as soon as the rows of plants can be seen the ground should be flat-hoed to destroy weeds; and, again, it will require hoeing before any crop can be cut towards the autumn. The crop will be best cut whether there is little or much produce, as this will clear away those weeds which may have survived the second hoeing. In drilling upon a fallow, however, the plants are liable to be attacked by enemies, such as wireworm and the little white slug, which do not injure them when sown in the corn; and therefore when we consider the expenses of hoeing, which in wet seasons cannot be done at all, we can only recommend the seeding in corn. With respect to the value of the crop there is no doubt that upon sandy land, sandy loam, or clay loam this plant will produce an abundance of green fodder, and more than any other plant. It is specially adapted for small farms with orchards. When cultivated under the trees or partially so the turf is broken up and dug-in, and the land seeded to lucerne and hoed every year. This partial tillage will wonderfully assist the growth of fruit trees, which in many cases with turf under become stunted and moss-grown. This cultivation, together with pruning, will soon produce favourable results.

The time has now arrived when top-dressings upon corn and grass lands may be applied with the best advantage. The dressings now most in use are 1½ cwt. of nitrate of soda with 3 cwt. of superphosphate, or 2 or 3 cwt. of Peruvian guano per acre. When either of these dressings are applied to pasture land 2 cwt. of salt may be sown with the nitrate of soda, and a small quantity of damp ashes mixed with the guano to prevent its flying before the wind, which often prevents a regular application. If we look to the analysis of these two dressings it will be found that they are very similar in their composition as regards nitrogen and the phosphates, and either dressing will have a stimulating effect upon the grass; the nitrate, however, acting quickest unless rain succeeds immediately after the application of guano. When we have a luxuriant crop of grass produced by these and such-like manures it will require the utmost care when the cattle, especially milking cows, are first turned into it, for in early spring after being fed on roots, cakes, hay, &c., the cows may suffer in various ways unless they have only a moderate quantity, or are grazed only for an hour or two at first. They may suffer from purging; this, however, cannot be considered a serious matter as affecting the animals. There is, however, often found upon highly manured grass after a night's frost or two a minute fungus produced on the leaves, commonly called "red rust." What effect this may have upon animals eating it we are not prepared to say, nor could we say that the prejudice existing against nitrate used on pastures has any justification, particularly, as is asserted, in producing abortion. In the absence of analysis of grasses manured with nitrate and other artificial manures, such as guano, we are not prepared to admit, nor do we believe that either scientifically or practically that injury to cattle can be inflicted unless by the injudicious use of the grass.

The planting of cabbages raised last autumn should now be going on. The sorts for succession as cattle food are first the Oxheart, the Champion, and last the Drumhead Savoy. If the land has been prepared in the autumn the dung may be laid out, and in the act of ploughing the dung may be raked into every third or fourth furrow, and then plant the cabbages on the furrow immediately over the dung. We prefer planting with the spade, as plants with any length of stem can be set without difficulty.

SYMPHYTUM ASPERRIMUM (PRICKLY COMFREY).

ONE of your correspondents asks for the experience of those who have tried it. It having been strongly recommended for cattle-feeding and as a plant which will stand drought, I sent out one thousand roots about three years since to the Rajawelle estates in Ceylon, where it was planted out and grew very fairly in moist weather, but the last accounts are that "it is suffering much from want of rain," none having fallen for six weeks. After being cut back once or twice it stools out and gives a good supply of herbage, but the cattle do not relish it. I also about the same time planted out a dozen roots in my garden, and, as in Ceylon, after being once cut it stools very fairly, but my cows

reject it. My horses did not refuse it, but then they had very little green meat given to them. The roughness of the leaves seems to be disliked by the cattle. Whether pigs will eat it I cannot say. My soil here is rather light, and I used no manure in planting it.—W. D. P.

POULTRY KEEPING IN TOWNS.

As a very large number of persons in the suburbs of London and other large towns keep poultry in confined situations they little know the great annoyance the birds are to many neighbours, who would think kindly of them if poultry owners would endeavour to prevent this. In many instances elderly people and invalids are deprived of much necessary rest by the incessant crowing of the cooks, Cochins and Bantams in particular, at early dawn. During the dark months of winter the crowing is seldom heard. I recommend all keepers of poultry to adopt the plan of every evening, when their fowls are gone to roost, of shutting them up in darkness till the morning. The fowl house might easily be so contrived as to keep them in total darkness by a slide to let down and pull up till the time the owners or servants are about. I think this would be very effectual and attended with little trouble or inconvenience. During the winter months this precaution would not be needed.—Q.

PIGEONS FOR THE TABLE.

It has often struck us as a pity that these delicious birds, so readily reared in large quantities, are not more easily and cheaply bought in England; even where they are to be had in the markets they are tough and dry, and utterly unlike those which we kill from our own Pigeon houses, or which are to be procured in Continental markets. Good henwives and poultrymen improve the flesh of their Turkeys, or Ducks, or fowls by special feeding; but it never occurs to them to feed their Pigeons with the same object. A Pigeon, too, is generally considered a Pigeon, and no attention paid to the particular breed.

The medium-sized Runts we have always found excellent on the table. Everyone who has tasted the delicious Pigeons of Italy will remember their flavour, and they are for the most part Runts; not the unwieldy monsters seen at our shows, and which are most careless mothers, but a bird about half their size in weight. We once found in an old poultry book a recipe for fattening young Pigeons on maize soaked in milk. The direction was that at three weeks old the young birds should be taken from the parents, and fed several times daily on as much of this food as they can eat. We observed not long ago a similar system pursued by a poulterer in Genoa. In a quiet out-of-the-way court or market he had a vast number of birds—Turkeys, Guinea Fowls, Ducks, Fowls, and Pigeons. These all lived in baskets in the open air till required for use, a plan which could hardly be carried out in this climate, though we believe they were taken into sheds at night. He showed us his various ways of feeding, but that which interested us most was the rapidity with which he fed his numerous Pigeons. He seized each bird with the left hand, and with the right thrust a funnel into its throat, into the mouth of the funnel he threw a handful of millet, and with a dash of water from a bottle sent the whole of it down the bird's throat; in this manner we should think he fed at least five birds a minute.

If pursued on a large scale some such plan might be a profitable one, for far more birds could annually be reared from one pair if taken from them at three weeks old than if left in the Pigeon house, where many get maltreated by other Pigeons, others starved by their parents too eager for fresh progeny, while others disturb their parents and cause their eggs to be spoilt.—C.

RABBIT CROSSES.

DID we believe in the Darwinian theory in its entirety we could easily explain the existence of so many breeds. If the human tribe was originally of the Pongo type, then we can easily understand that at one time all the varieties were identical, and that development has made the different varieties. Such a theory is the most simple one that can be adduced, and is the only way to account for the number of breeds in addition. The original type may have been large or small, or of the average, and the difference in size of the varieties may be very marked in consequence of the different classes of treatment, both in food and exercise, to which the various sections may at different times have been subject. Thus the warm climate of Spain, with the good diet of fruits and vegetables, may easily account for the improvements in the Lop variety, the ears being so much affected by the temperature. The long wool of the Angora Rabbit may have been caused by similar treatment to that which caused the Angora goat and sheep to be coated so beautifully. The strong sturdy limbs of the Chinese or Himalayan Rabbit may be attributed to the climate and the broad expanse of uncultivated, but notoriously rich, land through which they may have roamed. The Patagonian and the Belgian Hare both hail from central Europe, where a milder climate than ours

reigns. This no doubt has influenced their size, added to the care that has been bestowed on the question of Rabbit breeding and feeding by the inhabitants. Still it is strange that the little Dutch claims as its place of extraction a country but a few miles further north, and yet is so small. The only explanation is that the Dutch at home is not necessarily the same as the Dutch here, and that much of the diminutive is the work of a fickle fancy rather than an exact form of the breed.

In speaking of monstrosities we shall deal with foreign varieties that have been crossed, and more particularly with crosses that are decidedly heterodox. Pursuing our line of thought it is easy to imagine how that one breed having been formed another could easily follow, and that by crossing considerable variety might be made. Probably at one time there were but very few varieties, but that by crossing the number increased. Most of us can remember the formation of two new breeds, and all of us one. The latter is the Silver Cream, and the second one the Siberian. Both these formations were very simple, and no doubt many of the others came about in a similar way.

The Siberian is the result of a cross between an Angora and a Himalayan. The direct produce of a cross between these two is by no means perfect. The offspring in that case takes more after the father than the mother. If an Angora doe is placed with a Himalayan buck the young will have fairly dark points, but the wool most indifferent and not more than half its proper length. The feet are very likely to be very streaky, but the other points will be very dark but not quite so black as the father's. The frame will be weaker than that of the Himalayan, but much stronger than that taking of the Angora. Reverse, and pair an Angora buck with a doe of the Himalayan variety. The young will have fairly long hair or wool, but the points will be very light; the feet often are very grey in this case. Of course, development and careful crossing have improved the breed. The Silver Cream was at first a cross between two varieties, it is not very easy to say which, but it is now quite a distinct breed. A few crosses may be interesting to notice.

If a Dutch is crossed with a Himalayan the result will be by no means satisfactory. The dark points of the Himalayan are generally apparent in all the young ones, whatever the colour may be, the effect being strange. A Dutch with an Angora produces a litter almost solely composed of badly woolled and badly coloured Angoras. The wool is about two-thirds the right length, but more like the father than the mother. A Dutch and Silver-Grey cross is very weak, the beauty of both being quite lost, and most of the young ones being apparently only common Dutch Rabbits, and often of the poorest colours and marking. If the Dutch is fawn it is possible that a Silver Cream may be found in the litter, but no great reliance can be placed on it. A Silver-Grey, Belgian Hare, or Patagonian crossed with an Angora produce more or less badly-marked short-woolled Angora, the wool being longer if the buck be Angora than if a doe of that breed be selected for the cross. Cross any one of these three with the Himalayan, and both breeds will be deteriorated. The young will be grey and short hairs, the points being probably darker, something like the Himalayan. If Creams and Silver-Greys are crossed a very mealy shade of silvering is produced. Lops, of course, cannot be advantageously crossed with anything, because a cross must tend to shorten the ear. A Silver-Grey crossed with either of the very large breeds makes a healthy stock, valuable for feeding and killing. Belgian Hares and Patagonians may be crossed to obtain a capital mongrel, very large and heavy, and very easy to be fattened. It is the best for food that can be imagined. Polish crossed with Himalayans causes the points of the latter to be much weaker, and detracts from the health and strength. If either of the component breeds of the Siberian—that is, an Angora or Himalayan—be paired with one of the breed the result will be that the offspring take very much after the imported pure-bred.—GERRA.

VARIETIES.

FROM an excellent paper on "Farm Work in Harvest," read at the Central Farm Club by Mr. Rose of Melton Magna, Norfolk, we cite the following, which is worthy of attention at the time when land is being prepared for root crops:—By growing a larger breadth of land with mangolds we might in some measure facilitate harvest work, for by growing more of this valuable root the farmer must of necessity be in a forward place with his cultivation, besides gaining an advantage in being compelled to hoe them early in consequence of their early sowing. We also get more time between the hay and corn harvest for carting and spreading manure for wheat and for trimming fences before harvest commences. In speaking of early-sown roots as being important for us to grow so as to have all possible work completed before harvest I would not wish to omit making mention of kohlrabi, a most valuable root for feeding purposes, which should be sown early, and succeeds well on good land. There are even now some persons who cannot believe it is right to grow more than a third of the root land with mangolds; yet many of the best farmers in Norfolk are to a great extent discarding the growth of white

turnips either for early or late use, and it is an undisputed fact that mangolds are far more nutritious and better in every respect for either purpose than white turnips are.

— COPE's *Tobacco Plant* estimates that the tobacco annually consumed in the world amounts to about two thousand millions of pounds; and that if the leaves were made into a roll 2 inches in diameter we should have a "tobacco serpent" which, following the direction of the equator, would wind around the earth thirty times.

— THE extent of apiculture in America is so considerable that the product of wax in the United States is stated to be 20,000,000 lbs. annually, and increasing—worth in money at least six million dollars. Of this about 700,000 dollars worth are exported, and about 1,200,000 dollars' worth of honey also goes abroad. The total product of honey and wax is worth at present in the United States nearly five million dollars—upwards of £1,400,000.

— PIGS consume material that would otherwise be wasted, while they probably convert certain kinds of food into meat as economically as any other animals. They are capable of remunerative returns when properly managed. Aside from the necessities of home consumption, it must be remembered that low prices always induce increased consumption both at home and abroad. In 1876, says the *American Cultivator*, the United States sent abroad \$9,664,456 dollars' worth of bacon and hams, 5,744,022 of pork, 22,429,485 of lard; while in 1877 the exports had increased to 49,512,412 dollars' worth of bacon and hams, 6,296,414 of pork, and 26,562,665 of lard, or a total during the two years in English currency of £81,085,824.

— A GREAT proportion of the potatoes required for home consumption is drawn from the Continent, and Malta has recently helped to swell the supply. For the last few years the island has been steadily increasing its production, and the potatoes grown there are remarkable for their soundness—so much so that there is literally no waste whatever. Quite lately the steamer *Peshawar* brought over from the Mediterranean Arsenal 200 tons, which found a ready sale at about 9s. per cwt.—a most moderate price considering the excellent quality of the produce. As throwing some light on Continental sources of potato supply we annex a list of the imports into London during one week:—106,704 bags from Hamburg; 11,497, Antwerp; 13,522, Stettin; 8,202, Bremen; 2,074, Ghent; 771 sacks, 64 tons, Dunkirk; 771 sacks, Rouen; 892, Harlingen; 200 sacks, 150 bags, Boulogne; and 241 packages, Malta.

— THOSE are fortunate who have a good stock of mangold for the ewes and lambs. It is now that the value of this root is best seen; a moderate allowance, either cut up or thrown about on grass or seeds, is of great use in making milk. Decorticated cotton cake, palm-nut meal, and Indian corn are all low in price, and a small outlay in such materials will prove a good investment, not only for the ewes and lambs, but for young horned stock. It is a great thing to have the animals fresh for grass; no time is wasted in making-up lee-way; indeed, the great secret of successful rearing is to have the animals always progressing, and never stationary or going back; regular feeding is the secret.—(*The Field*.)

— FRANCE now counts twenty "agronomical" stations, where farmers can have soils, manures, plants, &c., analysed for a very small fee. There are plots of ground attached to these "field laboratories," where purely scientific agricultural problems are solved by direct experiment. The farm schools are institutions apart, and are more and more assuming the valuable rôle of representing the most approved practices specially adapted to the husbandry of their region. There is a total of 147 of those stations in Europe.

— THE experience of many thriving farmers, says an American writer, proves that better animals are obtained by breeding them on the farm than by purchasing them. More care is bestowed in selecting the likely offsprings of tried animals; they will go on fattening more rapidly and uniformly than strangers picked up here and there, for it takes some time before these get acquainted and become content enough to lay on flesh kindly in their new home: and, moreover, the tendency of prices for young stock is upwards, and the probability is very strong that ere long it will not pay farmers to go into the market for young animals. In any case it is, as a rule, more profitable to breed the stock one handles than to purchase it.

— THE supplies of potatoes at the Borough and Spitalfields Markets are limited, and the trade continues steady. Kent regents, 200s. to 240s.; Essex regents, 180s. to 190s.; ditto rocks, 100s. to 140s.; flukes, 200s. to 240s.; Victorias, 190s. to 220s. per ton.

THE HUSBANDRY OF BEES.

THOUGH I know some have written well and truly, and others more plentifully upon this theme, yet somewhat have I learned by experience (being a bee-master myself), which hitherto I cannot find recorded.

BEE HOUSES.—The first provision requisite for keeping bees is a house. Decay, rain, and weather destroy the hives and covers, and cold most of all is hurtful for the bees. Therefore you must have a house made along a sound and dry wall in your garden or in your orchard, for bees love flowers and wood. The form is a frame standing on posts with one floor (if you would have it held more hives two floors), boarded, laid on bearers, and back posts covered over with boards flatwise. Let the floors be without holes or cliffs; though your hives stand within a hand-breadth the one of another, yet will the bees know their home. In this frame may your bees stand dry and warm, especially if you make doors, like doors of windows, to shroud them in winter. Such protection I find that it strengthens my bees much, and my hives last six times longer than when exposed.

HIVES.—Mr. Markham commends hives of wood, I discommend them not; but straw hives are in use with us, and I think they combine handiness, closeness, warmness, and dryness. Bees love no external daubing or such-like. Sometimes occasion shall be offered to lift and turn hives, as shall appear hereafter. One light entire hive of straw in that case is better than one that is daubed, weighty, and cumbersome. I wish every hive for a keeping swarm to hold three pecks at least by measure, for too little hives procure bees in casting-time either to lie-out and lose time, or else they cast before they are ripe and strong, and so make weak swarms and untimely; whereas if they have room sufficient they ripen timely, and casting seasonably are strong and fit for labour at once. Neither should the hive be too great, for then the bees loiter and waste meat and time.

HIVING OF BEES.—Your bees delight in wood for feeding, especially for casting, therefore want not an orchard. A May swarm is worth a mare's foal; if they want wood they are in danger of flying away. Any time before midsummer is good for casting and timely; before July is not evil. I much like Mr. Markham's opinion for having a swarm in combs of a dead or forsaken hive, so they be fresh and cleanly. To think that a swarm of your own or others will of itself come into any such hive is a mere conceit. *Experto crede Roberts.* His smearing with honey is to no purpose, for the other bees will eat it up. If your swarm knit in the top of a tree, as they will if the wind beat them not to fall down, let the stool or ladder prescribed in the orchard do you service.

SPELKS.—The less the spelks are, the less is the waste of your honey, and the more easily will they draw when you take your bees. Four spelks athwart and one top spelk are sufficient. The bees will fasten their combs to the hive. A little honey is good, but if you want, fennel will serve to rub your hive withal. The hive being dressed and ready spelkt, rubbed, and the hole made for their passage (I use no hole in the hive, but a piece of wood holed to save the hive and keep out mice), shake in all the bees you can, the remainder will follow. Many use smoke, nettles, &c., which I utterly dislike, for bees love not to be molested. Ringing in the time of casting is a mere fancy; violent handling of them is simply evil, because bees of all other creatures love cleanliness and peace. Therefore handle them leisurely and quietly, and their keeper whom they know may do with them what he will without hurt. Being hived at night, bring them to their seat. Set your hives all of one year together.

SIGNS OF BREEDING IF THEY BE STRONG.—1, They will avoid dead young bees and drones. 2, They will sweat in the morning till it run from them, always when they be strong.

SIGNS OF CASTING.—1, They will fly drones by reason of heat. 2, The young swarms will once or twice in some fair seasons come forth mustering, as though they would cast, to prove themselves, and go in again. 3, The night before they cast, if you lay your ear to the hive's mouth, you shall hear two or three, but especially one above the rest, cry "Up, up, up," or "Tout, tout, tout," like a trumpet sounding the alarm to the battle.

Much decanting there is of and about the master bee and their degrees, order, and government; but the truth in this point is rather imagined than demonstrated. There are some conjectures of it—viz., we see in the combs divers greater houses than the rest, and we commonly hear the night before they cast, sometimes one bee, sometimes two or more bees, give a loud and several sound from the rest, and sometimes bees of greater bodies than the common sort. But what of all this? I lean not on conjectures, but love to set down what I know to be true, and leave these things to them that love to divine.

Keep none weak, for it is hazard oftentimes with loss. Feeding will not keep them, for being weak they cannot come down to meat. If they come down they die, because weak bees cannot endure cold. If none of these, yet will the other bees, being strong, smell the honey, and come and spoil and kill them. Some help is in casting time to put two weak swarms together, or, as Mr. Markham well saith, "Let them not cast late by raising them with wood or stone," but with imps, say I. An imp is three or four wreaths wrought as the hive, the same compass to raise the hive withal; but by experience in trial I have found a better way by clustering for late or weak swarms, hitherto not found out of any that I know. That is this: After casting time if I have any stocks proud and hindered from timely casting with former winter's

poverty, or evil weather in casting time, with two handles and crooks fitted for the purpose I turn up that stock so pestered with bees and set it on the crown, upon which so turned with the mouth upward I place another empty hive well dressed and spelt, into which without any labour the swarm that would not depart and cast will presently ascend, because the old bees have this quality (as all other breeding creatures have) to expel the young when they have brought them up. There will the swarm build as kindly as if they had of themselves been cast; but be sure you lay betwixt the hives some straight and cleanly sticks, or rather a board with holes, to keep them asunder, otherwise they will join their works together so fast that they cannot be parted. If you so keep them asunder at Michaeltide, if you like the weight of your swarm (for the goodness of swarms is tried by the weight) so caught, you may set it by for a stock to keep. Take heed in any case the combs be not broken, for then the other bees will smell the honey and spoil them. This have I tried to be very profitable for the saving of bees.—A KILKENNY BEE-KEEPER.

[This is extracted from "Way to Get Wealth," an old book published in 1638.—EDS.]

(To be continued.)

NATURAL DEATH OF BEES.

WHAT tidings of the loss of hives come to us from many apiarians! "I have lost all my hives." "Nine or ten of my twelve stocks are dead." "I have only one hive living out of four." "Have you any to sell? all the bees here have died out." "Every one of my bees is dead, and all have gone, leaving plenty of honey in the hives." A letter from a gentleman in Sheffield this morning says, "Last year was a very bad one for bees here, but by attention to mine (a swarm) I have succeeded very well, whilst my neighbours have lost nearly all their hives."

Some months ago I predicted that the loss of hives this spring time would be great, but I little thought that the fatality would be so great and general as it has been. No winter during the last eighteen years has witnessed the extinction of so many communities of bees. The cold of the winter of 1860 was signally disastrous to bee life in the north of England; but I fancy that more hives in proportion to the number kept have been lost during the last few months than were lost by the frost of 1860.

Neither frost, nor moisture, nor foul brood, nor dysentery, nor pestilence of any kind, nor hunger has been the cause of the loss of so many hives this spring or season. The bees have died a natural death, or in other words, of old age. The misfortune has been that the weather has been so unfavourable that they could not breed young bees to take their places before they fell dead on the boards by reason of age. Owing to last year being unfavourable for honey-gathering bees ceased breeding a month or two before the usual time of doing so; and as the spring months of this year have been cold and discouraging the bees of many hives never commenced breeding at all, and have died off naturally; the allotted span of their lives being but nine months, and many die before they reach that age.

Where bees have been artificially treated and well nursed things are not so bad, for in unfavourable seasons kindly treatment is a prime factor in the apiary. In time everybody finds that those who feed wisely and well are the most successful bee-keepers. In early spring when weather is cold there is a margin of risk in feeding which causes the bees to fly about and commence breeding, but in such springs as the present one there is a greater margin of risk in not feeding.

These occurrences are mentioned now with the hope that young apiarians will not be too much discouraged and cast down by their misfortunes, and that they will not trace their losses to their own mistakes or ignorance, for most of the bee-keepers in these northern parts have suffered loss from the ungenial weather of this spring. Two years ago we had a spring something like the present one, only not quite so bad and destructive, and the hives were in better condition and outlived the cold weather. Many of the hives then were greatly weakened by loss of bees before brood was hatched, but afterwards the weather became favourable, and we had a year of honey and success in 1876.

Some fifty years ago a bee-keeper in my native village bought twenty hives for £20. Eighteen of the twenty died during the winter following, and from the two that survived he had £20 worth of honey. We sincerely hope that the bee-keepers in the south of England have not sustained losses to the extent of those in the north, for if they have been equally unfortunate bees will be scarce in this country for two years. Many hives now living are so weakened by loss of bees that the season will be nearly over before they will be ready to swarm. Yesterday (April 11th) I saw my bees seeking for water, and to-day they have been busy carrying some from milkpans placed before their hives. Though I have not seen them seeking water this season before yesterday, they may have been doing so. Water is necessary in hives for breeding purposes. As soon as they begin to multiply and hatch brood they will make rapid progress. I shall be pleased if some of your readers will kindly inform us through the Journal how

the bees in their neighbourhoods have stood the stress and strain of the last few months.—A. PETTIGREW.

OUR LETTER BOX.

HENS' FEATHERS COMING OFF (*Amateur K.*).—The hens are moulting. They do so annually at this season.

LARGE EGG (*S. J. A.*).—Four ounces and three-quarters is a very large size, and very unusual.

FOOD FOR TUMBLERS, &c. (*A Beginner*).—You do not exactly state whether yours are Flying Tumblers or what are termed the Short-faced, but we apprehend the latter, as you mention Kites and Mottles being among them. Old tares are without doubt best for Short-faced Tumblers, and we would advise giving them to them without any other food. Maize, unless it be a very small sort, is too large. As to peas they seem to be the natural food for Pigeons, and which they prefer to anything else, but are only suited for the commoner kinds or more naturally bred birds. If your Tumblers are flying birds we should not give them such expensive food as tares; maize and peas are quite good enough. If you have the high-class birds only give tares with wheat in moulting time to keep them in flesh. If you can get very small old beans they are excellent, but usually are too large for the throats of the birds. From a Kite cock and Red Agate hen the progeny will most likely be one of each colour.

HIMALAYAN RABBIT (*Rubry*).—There is a full description and an engraving of this Rabbit in our manual entitled "The Rabbit Book."

REMARKS.

10th.—Bright morning; fair and dull, little sunshine between 1.30 and 2.30 P.M.; rain at 5.15 P.M., and during the evening.
11th.—Very heavy rain all night, and continued till 1.30 P.M.; fine afternoon; 12th.—Fine warm sunny day; bright moonlight night. [starlight night.
13th.—Misty morning, fine after 9 A.M.; cloudy in afternoon, rain from 4 P.M. to 5.30; dull evening.
14th.—Fair rather overcast day; sunshine between 2 and 3 P.M.; cloudy night.
15th.—Dull close morning; sunny and bright in afternoon; fine moonlight night. Lunar halo 8.30 P.M. to midnight. [ing about an hour.
16th.—Wet morning; fair after 11.30 A.M.; thick mist and drizzle at 3.30, last. The week is remarkable for containing one of the heaviest falls of rain, which have occurred in the metropolis. Slight rain began in the evening of Wednesday, and between midnight and noon on Thursday the remarkably large fall of 2.80 inches occurred, producing serious floods in many places.—G. J. SYMONS.

COVENT GARDEN MARKET.—APRIL 17.

WE are now better supplied with new Grapes than we have ever been in previous years, the majority arriving from the Channel Islands in good condition and forward in point of quality, the value of home-grown fruit being materially affected thereby. Strawberries are reaching us in better supply, and for a few days will find an inferior market. French early vegetables have now commenced, and consist of Asparagus, Beans, Turnips, Carrots, Artichokes, and salading. Trade quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 68.7°; and its night temperature 37.3°.

BRITISH FERNS AND HARDY FERNERIES.

IT is now fifteen years since I first became acquainted with and commenced admiring British Ferns. I was then in the employment of a lady who, for the deep love she bestowed on these highly interesting plants, took numerous excursions from home to gather the real wild varieties in their own natural habitats. These she conveyed to her rockery, where she planted them almost entirely with her own hands and gave them her personal attention. The collection she thus formed was an excellent one, and the plants could not be surpassed for luxuriance. This lady also contributed under the signature of "FILIÆ-FEMINA" to the pages of the *Journal of Horticulture* during the autumn of 1864 some valuable notes on hardy Ferns, and described most fully how she collected and cultivated them. I cannot pretend to describe so minutely as did this accomplished pteridologist the beauties of each variety of Fern, but I may mention several Ferns that from experience I can recommend to those of your readers who may wish to possess a small rockery and a collection of these charming plants.

The present month is about the most favourable season of the whole year for planting outdoor ferneries. Many Ferns are now just commencing their new growths, but are not sufficiently far advanced to allow of the spring frost injuring the young fronds. When early growth is made and late frost occurs it interferes with the after progress of the plants, otherwise they will grow away as soon as planted and become firmly established before the hot weather of summer has fairly set in.

The best site for a fernery is undoubtedly where the plants will enjoy the advantage of being protected from brilliant sunshine and rough winds. In almost any out-of-the-way corner an enjoyable little rockery may be made, but under the drip of trees is perhaps the worst possible place that can be selected for planting a collection. In a position where they have shade during the day and yet where they can enjoy a little of the morning and evening sun they thrive admirably. It is also a great advantage to have at the fernery, or near it, a supply of water, for during the summer season the plants must be watered copiously overhead, and if the water can be laid on so as to trickle down the rockwork it is always grateful to the Ferns, and cooling and refreshing on a summer's evening when everywhere else is hot and parched.

The manner of constructing the fernery must be determined by the space at disposal and the material that can be procured with the least amount of trouble and expense. Rough blocks of stone, bricks which have run together in burning at the kiln and known as "burrs," or clinkers saved from the stove fires, and ordinary bricks put together in irregular masses with cement, will all answer the purpose. The rockery should be made in the most natural manner possible, and plenty of space should be left for holding sufficient soil to afford nourishment to the plants in dry seasons; this is very important. Equal parts of turfy loam

and leaf soil with a fair quantity of silver sand will be found suitable to the majority of the hardy Ferns; they will, however, succeed fairly well in ordinary light garden soil. In planting them care should be taken to arrange the evergreen and deciduous varieties, so that in winter when the deciduous kinds have lost their fronds the evergreen Ferns will impart a cheerful appearance to the rockery.

The evergreen varieties are represented, amongst others, by *Scolopendrium vulgare*, *Blechnum Spicant*, some of the *Lastreas* and *Aspleniums* and their numerous garden varieties. The somewhat common Hart's-tongue (*Scolopendrium vulgare*) is a grand Fern, and will grow in almost any soil or situation. It is sometimes found growing out of the crevices of high walls, but oftener in moist and shady positions, in which situations its distinct glossy green fronds render it very attractive, while in more exposed situations it loses its deep green hue. Many of its varieties, of which there is a very large number, are remarkably fine, especially *S. v. crispum*, *S. v. cristatum*, *S. v. marginatum*, and *S. v. ramosum*. Others are very curious in form, while some few are proliferous. I well remember finding a simple crested form growing very plentifully in Devonshire, and once while on a visit to the Undercliffe, Isle of Wight, I saw the largest specimens growing in greater quantities than I have ever seen before or since. When the *Scolopendrium* is planted in the rockery it requires a deep soil to grow it to perfection, which probably accounts for the luxuriant specimens seen in the Isle of Wight.

Blechnum Spicant is a very common Fern, and is found in great abundance in Devonshire; nevertheless it is very distinct, and when planted in a shady nook it has a very pleasing and attractive appearance. Its fertile fronds growing erect and situated in the centre of the tufts of barren fronds which grow generally horizontally, and its thoroughly evergreen nature, commend it to the most limited of collections.

Ceterach officinarum is a dwarf evergreen distinct-looking Fern, and is found growing on old walls, bridges, &c., but will not bear removing well.

The *Polystichums* or Shield Ferns are remarkable for their bold and handsome growth, and can be highly recommended, especially *P. angulare*, *P. a. proliferum*, *P. a. p. Footii*, *P. a. p. Woolstoni*, *P. a. biserratum*, *P. a. cristatum*, *P. a. grandidens*, *P. a. oxyphyllum*, and *P. a. plumosum*. The proliferous varieties produce bulbils very freely on the fronds, which if taken off ultimately become plants.

Lastrea Filix-mas is a very bold-growing Fern, and is invaluable for forming a background for the choicer kinds, while several of the garden varieties of this well-known Fern are most elegant in growth and deserving the most prominent positions in the fernery, most of them being both curious and constant in their variations. The most valuable are *Lastrea Filix-mas Barnesi*, *L. F.-m. crispa*, *L. F.-m. cristata* and *L. cristata aspera*. *Lastreas æmula*, or the Hay-scented Fern, *L. Oreopteris*, *L. dilatata*, and *L. Thelypteris* are also very distinct and good; the latter variety is generally found growing in moist swampy places, and requires treating accordingly: plenty of moisture at the

root and plenty of room to spread are its chief requirements; it is then very attractive.

Some of the Aspleniums are very small-growing Ferns and remarkably curious, especially *Asplenium septentrionale*, *A. germanicum*, and a much more common variety, *A. Ruta-muraria*. These do not usually succeed well under outdoor cultivation, although I once grew a plant of *A. septentrionale* in a pot for some years. *A. fontanum* also makes a very fine pot plant, and may be plunged in its pot during the summer months in the rockery. It is not at all suited to the requirements of the outdoor rockery. *A. marinum* is remarkably beautiful; its deep green fronds are exceedingly pretty, but it also is too tender for the outdoor fernery excepting in the south and south-western counties. I have seen it growing out in a rockery at Teignmouth, Devon, and doing well. It requires a moist atmosphere. *A. Adiantum-nigrum* and *A. Trichomanes* are very pretty, and can be grown successfully in almost all parts of the country; the hedgebanks of the lanes of Devonshire abound with these two species, and so luxuriant are they there as to almost grow out of their natural size and character, especially *A. Adiantum-nigrum*. *A. viride* is a companion to *A. Trichomanes*, but is not so common, being found only in the north of England. Its mid-stem is white, while that of *A. Trichomanes* is black. *A. lanceolatum* is attractive, and will grow well in the south of England. I once found a very large mass of this Fern growing on some rocks on the banks of the Plym not far from the embankment of the railway which passes along that valley. When that railway was formed many tons of solid rock were blasted and carted away for making the embankments, until in many places there were over 80 feet of hard bare rock left. Seventeen years afterwards I was surprised to see luxuriant Ferns, Gorse, and even young forest trees growing in the fissures of those rocks; the collecting decayed vegetation with the humidity of the climate afforded the requisite nourishment.

All the Lady Ferns (*Athyrium Filix-foemina*) are so beautiful and distinct in character that they should be planted rather extensively. They are quite hardy, and during the summer months their young, graceful, and delicate-looking fronds are highly attractive. Some extremely fine specimens of the Lady Fern growing quite naturally and unprotected, and measuring over 4 feet in diameter, I once met with in a wood in the neighbourhood of Poynton, Cheshire, between Hazelgrove and Disley. Numerous varieties are now in cultivation, and they possess such varied points of beauty that they are not surpassed by any of our exotic species. Of these varieties the following can be recommended:—*A. F.-f. coronatum*, *A. F.-f. corymbiferum*, *A. F.-f. crispum*, *A. F.-f. Fieldiae*, *A. F.-f. Friselliae*, *A. F.-f. lacinatum*, *A. F.-f. multifidum nanum*, *A. F.-f. plumosum*, *A. F.-f. Vernoniae*, and *A. F.-f. Victoriae*. This last is the finest of all the crested forms of *Athyrium*.

Osmunda regalis and *O. r. cristata* are true bog Ferns. The last is a very pretty crested form of *O. regalis*. Planted by the side of water or plentifully supplied with moisture they grow most rapidly and are very handsome.

Nearly all the Polypodiums must be included in the selection, especially *Polypodium vulgare* and its varieties *cambricum*, *omnilacerum*, *pulcherrimum*, and *semilacerum*, which are all beautiful. They grow freely if planted shallow in good soil and have plenty of drainage. The Beech Fern, *P. Phegopteris*, and the Oak Fern, *P. Dryopteris*, are deciduous, but their delicate fronds of the softest green are most lovely during the summer months. They should be planted in peat and leaf soil in a shady nook and in a position so that they may not be smothered by the more robust growers. The dwarf-growing and somewhat curious Moonwort, *Botrychium Lunaria*, and Adder's-tongue, *Ophioglossum vulgatum*, are worth a place in the fernery, but are difficult to establish, especially the first-named. An uniform state of moisture and a sharp look-out for slugs (which are very fond of them) is the best advice I can offer. The Adder's-tongue is of very free growth and plentiful in some localities in the meadows. On the banks of the Medlock, near Manchester, I have seen the fields literally covered with it. The pretty little Mountain Parsley Fern is admired by the most fastidious, and succeeds very well out of doors if planted in a shady nook of the rockery.

To possess a complete collection of all the British species and their varieties would involve the expenditure of a large amount of money, but those named will be found sufficient for most beginners, and can be purchased for a moderate sum, many of our nurserymen supplying them from £5 to £7 10s. per hundred, according to variety. I avail myself of this

opportunity of warning purchasers from buying from those hawkers who ply with a basket at their back, for oftentimes what they offer for sale are the proceeds of someone's rockery. I had over thirty rare varieties stolen in this manner during the past winter.

Those who desire to grow Ferns and yet cannot avail themselves of a small rockery, may cultivate the smaller-growing varieties under a bellglass or in Wardian cases in rooms, or on window-sills, for the cultivation of hardy Ferns is, as a rule, very simple and easy. A liberal supply of water both overhead and at the roots during their growing season, a slight protection from late spring frosts, and a sharp look-out for snails, slugs, and woodlice, are the greatest essentials to success.

It will be seen that I have not mentioned the utilising of roots in the formation of ferneries. I am no advocate for them from the fact of their speedy decay, but at Belvidere House, Wimbledon, Mr. Lyne, the excellent gardener there, in making a large rockery intermixed roots with the burrs. Roots in most cases resting on a basement are in a great measure preserved from decay. This rockery is very well arranged, and forms an agreeable feature in a secluded part of the garden.—J. W. MOORMAN.

ROSES INJURED BY SPRING FROSTS.

"DON'T shout before you are out of the wood." Such, I doubt not, will be the truism which will occur to many of your readers as they glanced at my article on the late winter, or at least the kinder-disposed and more gentle critics may murmur this: but I can well imagine the sterner and severer subscribers, such as those who dwell in the midlands and are blessed with the grand Rose soil of those fertile lands, uttering quite different language. "Has this 'WYLD SAVAGE' lost his head altogether now? Is he no longer merely wyld but a raving lunatic? If not what does he mean by writing of the winter being over and the mildest season he has known, when as we read his effusion we have but to look out of the window and see snow 2 or 3 inches deep?" I can but bend my head to the storm, and answer that I have laid myself open to all kinds of unfavourable remarks; but I would ask those who may condemn me, Who would have thought that at the very end of March and the first week of April we should have had such weather? A writer in one of the daily papers commenced a leading article on the 1st of March "We may consider the winter over now;" and I did not write till weeks after this, but my letter being deferred for a week caused the sad (to me) result of my speaking of a mild and genial time for Roses at a time that winter raged with all its fury.

I have, alas! a very different tale to tell now. My Roses have suffered fearfully, and I am confident that if I had pruned so hard as I have been accustomed of late to do I should have lost my whole collection. As it is I have to mourn the decease of many of my best Teas, and the rest are sadly mauled. The late weather has deferred the blooming season for at least a fortnight, and I shall be surprised if the day fixed for the National Rose Show is not much too early for the generality of Rose-growers.

The question next arises, What to do now with the damaged Roses—how to repair the ravages which Jack Frost has made among our cherished pets? I am inclined to advise (and as I write I tremble at the thought of the responsibility I incur) your subscribers to re prune their Roses, to cut away all damaged wood even at the cost of delaying the blooming for a week or so. It is evident that unsound wood only damages the trees. The sap cannot flow freely through wood that is killed on one side, nor can good blooms be expected from trees that have shrunken limbs and diseased blood flowing in their veins. True indeed in this case is the old adage, "Spare the rod (i.e., the knife) and spoil the child," though in its primary sense most of the present generation think it a mistake.

All who had mulched their Roses in March will, I think, have found out the great value of their care and labour, for wherever the Roses have been mulched they will be found to have suffered much less from the frost. I have been much struck at the difference between those few that I have been able to mulch and the mass of unmulched trees. The only hope we have now is, that as we have had such weather in April we may be spared the usual rigours of an English May. If we have but a genial May we shall have a glorious Rose season, but if in addition to the damage caused by the late frosts and snow we have the usual bitter nights in May I do not know what will become of us.

The schedules of the National Rose Show are now issued, and wonderfully liberal they are. I think that they reflect the greatest credit, not only upon the Society in general, but on the members of the Executive Committee in particular.

There is only one remark I should like to make, and that is to ask why the Committee has made the hard and, as I think, unfair rule, "No exhibitor's tickets will be issued." This means, I suppose, that we shall have to pay admission money for our assistants and ourselves if we leave the building.

Last year at St. James's Hall no passes were given to our gardeners, and I do not think such a proceeding either liberal or just; but now it seems no tickets at all are to be issued, and so I suppose even subscribers will have to pay at the doors if they leave the Palace.—WYLD SAVAGE.

VEGETABLE CULTURE.

CHAP. XV.—BEET.

THE original form of Beetroot, which is very inferior to the varieties now cultivated in our gardens, is a native of the south of Europe. Beetroot is a very excellent vegetable when boiled or baked and eaten with cold meat; it is also an important ingredient of salads. As yet it can hardly be called a cottager's vegetable, because few of them grow it, but in all gardens of any pretensions Beetroot is one of the leading root crops, and no doubt its cultivation will increase amongst amateurs and cottagers when they find out its true worth.

Like all deep-rooting crops Beet requires deep soil to grow it properly. In a shallow soil the roots are very liable to fork into a number of small finger-like roots, but in a deep, free, open soil they push down one straight root from 18 inches to 2 feet in length. Soil which grows Carrots and Parsnips well always produces fine Beet; but Beet is much easier cultivated than Carrots, and it will often thrive and come to perfection in soil and gardens where Carrots fail. We generally grow our Beetroot and Parsnips side by side on the same piece of ground. During the winter or early spring the ground is trenched 2 feet deep, and at the same time only a little thoroughly decayed manure is mixed with the soil. Where the ground was heavily manured for the previous crop it is better not to add any more dung for the Beetroot, because this has always a tendency to cause the roots to fork. Previous to sowing the seed the surface of the ground should be broken with the fork, and turned over two or three times when it is dry. The only thing to avoid in sowing the seed is not to sow it too early. When this is done most of the crop is generally lost in autumn through the plants running to seed. During the last week in April is a good time to sow the seed for the main crop. A little seed may be sown a fortnight earlier than this when a few early roots are wanted, and a few rows might be sown later than the time named. An exposed part of the kitchen garden answers better for Beet than a shaded place. The seed should always be sown in drills 15 to 18 inches apart, and about 1½ inch deep. The seed is much larger than that of many other vegetables, and it need not be sown all along the rows, as two or three seeds dropped together 10 or 12 inches apart are sufficient to produce a crop. In covering up the seed the soil should be pressed very firmly with the rake. The seed is not long in germinating, and as soon as the young plants are distinctly seen the hoe must be run amongst them. I have recommended this practice so often now that it will be seen that hoeing is a system here, and it is a very excellent one. When the young plants are 2 inches high the plants in each tuft should be reduced to two. Hoe after this again, and when the plants are 4 inches high the permanent crop should be left singly. Hoe again after doing this, and continue to do so at intervals of a fortnight until the leaves have quite met in the rows, and after this the crop will mature without further attention.

Beetroot will not stand in the open ground throughout the winter and retain its qualities, therefore the roots have to be taken up and stored. The best time to take them up is about the end of October or early in November. The roots require to be very carefully dug out of the ground, because when they are the least broken the juice flows out and they are spoiled. For this reason in taking off the leaves they must never be cut close to the crown, but 3 inches from it. The roots should only be taken up when the soil is dry, and no attempt should be made to clean the soil off them as they are lifted, but after they have been spread-out in an open shed for a few days to become partially dry the roughest of the soil may be rubbed off with the hands, and the roots stored in layers amongst

dry sand in a cool shed or cellar. Here they must be turned occasionally and the decaying roots be picked out.

At this period of the year many of the crowns begin to sprout. These growths must be rubbed off when the roots are turned, and now they should not be laid in such large heaps as they were at first, as close packing encourages them both to grow and decay.

Dell's Crimson and Pine Apple Beet are our two favourite sorts, as they are both handsome and not too large in form, and are excellent in flavour and colour. Seakale Beet is cultivated like the other sorts, but the ribs of the leaves and not the roots of this variety are eaten. When cooked like Seakale few would know the difference between the two vegetables. Two dozen plants will supply many dishes, and all who care for Seakale in winter and spring should grow this Beet.—A KITCHEN GARDENER.

THE POLYANTHUS.

ONE of the most interesting features at the Newcastle-upon-Tyne Spring Flower Show was the collections of Polyanthus. Some of the plants, and especially those that stood highest on the prize list, were exceedingly well grown, and it was a great treat to see some of the old sorts that were grown nearly half a century ago. George IV. (Buck), for instance, what a splendid flower it is when well grown in the northern air! None of the recently raised varieties are anything nearly so good. The finest variety, Pearson's Alexander, was not exhibited, but it is in the hands of some of the growers, and no doubt it will be seen soon and take its place at the head of the lists as it did fifty years ago, followed by George IV. I know it would be interesting to the growers of the present day to know the names of Polyanthus cultivated when our fathers were young men, and as I have recently heard of many of these varieties being still grown I will give the names of all the best sorts in the hope that some correspondents of the Journal will state what sorts they still have under culture. They stand very nearly as under in the order of their merit:—Alexander (Pearson), George IV. (Buck), Prince Regent (Cox), Princess Royal (Collier), King (Nicholson), Invincible (Crownshaw), Jolly Dragoon (Eckersley), Bang Europe (Nicholson), Lord Crewe (Clegg), Prince of Orange (Cartwright), Lord Nelson (Park), Formosa (Burnard), Tantarara, Countess, Lord John Russell, Commander-in-Chief, Mary Ann, Beauty of Over, and Othello. There are some good varieties of more recent date, some of which are rather scarce and others are common. President, Exile, and Cheshire Favourite are plentiful, and such sorts as Sanderson's William IV., Rev. F. D. Horner, and Lancer are to be obtained.

The culture of the Polyanthus is very simple. The plants are much hardier than the Auricula, and do not require any protection from glass except when they are in flower to protect the bloom, and during severe weather in winter from cold rains, snow, and severe frost. I have grown the plants in pots all through the season; but I am not sure that is the best way to obtain the greatest results. I find if they are kept in pots and treated the same as the Auriculas the leaves are repeatedly attacked by green fly and red spider, and the pests have to be destroyed by dipping the whole plant in a solution of Gishurst compound or soft soap dissolved in boiling rain water, and adding to it a little tobacco liquor. Either of these mixtures will be death to the insect pests. Care must be taken not to make it too strong. If there is any thought of danger the best plan is to dip a plant that is of no value in the mixture and wait the result for a few hours, and if it is not injured the mixture may be at once used.

The best plan is to devote a frame in a cool place entirely to Polyanthus, and the plants should be watered overhead every day in hot weather. A good plan is to plant out of doors during the summer months. I have seen the plants do remarkably well planted out in deep rich clayey loam behind a north wall, and all the attention they require is a good soaking of water once a week in dry hot weather. Under such circumstances they are seldom attacked either with green fly or red spider. If they are planted out the plants must be lifted and potted about the end of August or early in September, so that they may be well established before winter. I pot them in rich clayey loam, and add to it about a fourth part of decayed manure and a little leaf soil. The plants are potted firmly, and they are placed in a shady place until fresh roots are formed. If the leaves are perfectly clean in the autumn the plants will start strongly in the spring. I do not allow any

water on the leaves after they start into growth at that season, but admit plenty of air at all times.

Ordinary border varieties make a very fine display if planted out in rich soil, and the best way to raise a stock is to sow seeds of a good strain in May or June; sow out of doors in fine soil, and when the plants are large enough prick them out about 3 inches apart, and when the leaves have nearly covered the ground they must be again transplanted into their blooming quarters; if in beds, 9 inches apart, where they will form a perfect carpet of bloom in the spring of the following year.—J. DOUGLAS.

FRUIT TREE PRUNING.

FOR the nonce I am constrained to assume the post of signal-man, and to hoist the signal for "caution" lest the communications which have lately been published on this subject should induce any unsuccessful fruit-growers to rush from one extreme to another, and in future to do too little as they have hitherto done too much with their pruning knives. There can be no question that pruning has been sadly overdone, that the supply of fruit has not been in proportion to the labour and care bestowed upon the trees, and above all that the expectations formed of the results attendant upon a rigid system of pruning and pinching by line and rule were opposed to the dictates of reason and common sense.

Why do we prune a fruit tree? To regulate its forces so as to secure an equal distribution of vigour in every part of it, to admit light and air freely among all the branches, to induce an abundant lateral growth upon every branch, and to promote the formation of fruit buds at an early period of its existence. We also seek to confine the growth within certain limits so as to adapt the tree to a confined space, where it may be sheltered in spring from the baneful effects of cold cutting winds so often fatal to the blossom, and in autumn from those gales which so frequently beat off the fruit. Lastly, we prune a fruit tree in order that every part of it above ground may be turned to account for the production of fruit. When therefore such a tree has attained its full development it should consist of a main stem, from which spring branches at regular intervals, each branch having a lateral growth of "spurs" upon every part from its junction with the stem upwards to the top.

For the benefit of the uninitiated it may be explained that a "spur" consists of a lateral or side shoot shortened to three or four buds, the shoots from which buds being in turn nipped off when they have grown a few inches in length, and it is the repetition of this nipping process that has much to do with early formation of fruit buds. Now, it is upon the spurs that the fruit comes, and the quantity of fruit in a favourable season will be pretty much in proportion to the length of the branches, the size and vigour of which must of course affect the size and in some degree the quality of the fruit. Such being the case, how can we reasonably expect much or fine fruit off a weakly tree or one stunted to the absurd degree so often practised? I am quite within bounds in stating that I have frequently seen trees upon which pinching and pruning has been carried to such an extreme that each of them, stem and branch, were very little larger than one of the bottom branches of a respectable "pyramid." So eager had the owners been to obtain fruit that not an inch of growth had been suffered to grow beyond the line-and-rule limits. With such toys no practical fruit-grower would care to have anything to do, for they illustrate an extremely bad practice just as forcibly as do those others from which the annual crop of flower stakes is taken in winter.

But there is a medium to which attention may now be usefully called, for at no period of the year than the present can so correct an estimate be formed of the value of any process of culture. The swelling buds afford clear indication of the effects of our treatment up to the present time; and although it is usual to point to a fine crop of fruit as the best indication of success, it may fairly be claimed that if now the branches of a large vigorous tree are thickly set with blossom buds, the formation of which has been brought about by a special process, that process is a good one which cannot be condemned because an ungenial spring proves fatal to the blossom.

Seven years ago I planted an extensive collection of fruit trees, all of which have been subsequently pinched and pruned in moderation, the condition and progress of each tree being the sole guide and rule in its treatment. The trees were planted well, have grown well, and have borne some fruit, some of them yielding a good deal of excellent fruit in the

third year after planting. In 1875 and the following year most of the trees formed enough blossom buds to give promise of really plentiful crops, but two springs of extreme cold led to almost total failure, very little of the blossom being saved. This year blossom buds are more plentiful than ever, and I hope we may at length be rewarded with an abundant crop of fruit. However this may prove, there stand the trees so full of promise that one feels tempted to enlarge upon the whole of them. To do so would require a series of communications such as I have no time for yet, and it will suffice if my remarks now are confined to the Apples. Most of these are pyramids of an average height of 9 feet, and with a diameter at the bottom also of 9 feet; some are much higher, and some a little smaller. They are planted in pairs for the most part, and some few of the most reliable by dozens. Of the sorts having the blossom buds crowded I may take Old Nonpareil, Manks Codlin, Hawthornden, Fearn's Pippin, New Hawthornden, Nelson Codlin, King of Pippins, Pomme d'Api, Cellini, Duchess of Oldenburgh, Ashmead's Kernel, Barcelona Pearmain, Lord Suffield, Cox's Orange Pippin, Sturmer Pippin, Margil, Wormsley Pippin, Golden Russet, Golden Reinette, Scarlet Nonpareil, Adams' Nonpareil, Ross Nonpareil, Ribston Pippin, Pomona, Boston Russet, and Hubbard's Pearmain. Of others having an abundant crop of bloom buds there are Kedleston Pippin, Small's Admirable, Kerry Pippin, Mère de Ménage, Dumelow's Seedling, Warner's King, Northern Greening, Golden Noble, Bedfordshire Foundling, Tower of Glamia, Hanwell Souring, Rymer, Yorkshire Greening, Court of Wick, Gooseberry, Cobham Apple (this is a regular giant 14 or 15 feet high, yet with plenty of blossom), Lord Burghley, Emperor Alexander, Reinette du Canada, Golden Pippin, Pearson's Plate, Reinette Van Mons, Melon Apple, Cockle Pippin, and Cornish Gillyflower.

I might extend this list still further, but enough variety is given to show that most sorts of Apples by a careful system of pruning and pinching may be rendered perfectly fruitful, and at the same time be brought to such a size as to afford bushels rather than dozens of fruit. There are certainly exceptions. For example, Brabant Bellefleur has very few flowers, Bess Pool though somewhat shy has more, so has Northern Spy; but I may inform "A COUNTRY PARSON" that it is notorious that this variety does not yield full crops of fruit until the trees are upwards of a dozen years old. I may advert to some little trees of Cox's Orange Pippin planted two or three years ago, and now about 5 feet high, with four or five dozen blossom buds on each, and there are some Ribston Pippins equally precocious.—EDWARD LUCKHURST.

AURICULAS AT SLOUGH AND LOXFORD.

ON the day of publication of this issue of the Journal the great gathering together of Auricula growers will be assembled at the Crystal Palace. The plants, or many of them, alluded to in these notes will also be arranged in the central transept of the great building, and before the day closes will have won high honours—at least, if it is not so the quality of other exhibits will be of unexampled superiority.

It is evident by the condition of the Slough and Loxford collections that the Auricula when it is handled by master cultivators is a southern as well as a northern flower. It is, in fact, a flower for all latitudes of Great Britain, and when well tended it will yield greater beauty in less space than perhaps any other flower in cultivation. The two master cultivators in the south of England are undoubtedly Mr. Charles Turner at Slough and Mr. Whitbourn's successful gardener James Douglas at Loxford Hall. At the Palace thousands will be admiring the flowers of those cultivators while thousands more are reading these lines. Such shows as that alluded to are almost indescribably beautiful, but an inspection of the flowers at home enables hints being gathered which cannot be picked up at a public exhibition. It is certain that many, probably many hundreds of visitors, on inspecting the great Auricula Show will ask the twin question, How and where are such beautiful flowers grown? A visit to the homes of their growers affords the best answer to such reasonable and natural inquiries. I will first glance at the collection at

SLOUGH.

This is known as the head-quarters of the finest trade collection of Auriculas in the world, and never have the plants been seen in better condition than during the present flowering season. Mr. Turner's catalogue list of varieties is an extensive one, but it by no means represents all the sorts that are grown in his nursery. So great is the demand for

Auriculas now that as far as possible only those are "listed" of which a reasonable number of plants are provided, and even then the stock of some of the choice, rare, and popular varieties is, to employ a nursery phrase, speedily "run off its legs." On this account Mr. Turner must always meet the more celebrated private growers at a disadvantage in the exhibition hall; for while they can keep and grow to vigorous plants such fine sorts as George Lightbody, Col. Taylor, Admiral Wisbey, Taylor's Glory, and others of that calibre, such celebrities cannot be retained at Slough until they reach their best exhibition form. Still many fine examples of choice Auriculas are represented there, and some which are notable for their free growth and great decorative excellence are in grand condition.

On page 304 Mr. Harrison Weir gave advice that is no doubt theoretically sound. "Have the best varieties," says Mr. Weir, "at starting—those that want most care, and they are sure to be well looked after," such as George Lightbody, a variety which your correspondent justly treasures both on account of its intrinsic value and the source from whence he obtained it. "Happy is he," concludes the great artist, "who grows Auriculas well," to which may be added, Happy is he who can obtain the best at starting.

The two Auriculas at Slough that, perhaps, more than any other varieties strike the genial visitor are two of "Turner's own"—Col. Champneys and Charles J. Perry. Neither of these varieties may be quite up to the orthodox standard of the Auricula connoisseurs, but there is nevertheless no disputing their beauty. The grand character of the grey-edged flower with its smooth pip and violet ground colour, the stately growth of the plant, and its powdered serrated foliage, render it extremely attractive, while the noble truss and the remarkable richness of the self constitute it one of the most imposing, not only of the class to which it belongs, but of all flowers expanding in April. These two Auriculas should be obtained "at starting," because they are certain to give a fine return for any cultural care bestowed on them, and if a little mistake should occur, as mistakes will occur with beginners, the innate vigour of such free growers as these will preserve them from the fate which not occasionally befalls other sorts of more perfect qualities, yet of more delicate mould. But the cultivation of such Auriculas as the pair named should not be limited to "fanciers." The flowers possess a decorative value which should not be overlooked. Where dwarf-growing and beautiful flowers are coveted in the spring as front row greenhouse decorative plants "Champneys and Perry" should be grown by the dozen, for no plants of the same stature can surpass them, and few can equal them in richness of effect. A few others, especially in the self and Alpine classes, are also, perhaps, nearly equally valuable for the same general purposes of floral embellishment.

Many varieties of greater value, judging them from the florist's standard, were admirably represented in the Royal Nursery this spring. Amongst white edges, which are not by any means over-plentiful, a new variety, Omega (Turner), is a flower of great promise, possessing as it does size, form, purity, and richness. In the same section Arabella (Headly) commands attention, as also does Highland Queen, a queenly flower, somewhat resembling yet distinct from and superior to Bright Venus. Heap's Smiling Beauty and Hepworth's True Briton are standard flowers in this section and likely to remain so. Cunningham's John Waterston is a flower of rare beauty, but is a silvery grey rather than a white as seen at Slough. Amongst the green edges Gertrude Knight (Turner), Atlas (Lightbody), Admiral Wisbey (Headly), Smith's John Bright, a fine solid green; Traill's Rev. George Jeans, Oliver's Lovely Ann, Hudson's Apollo, Gain's Lady Richardson, Lord Nelson, and Kaye's Splendour are represented by flowers of rare excellence. Amongst grey-edged varieties Headly's George Lightbody, a small plant at Slough, is certainly one of the finest of Auriculas. Only a little dexterous manipulation is requisite to transform it into a fine green-edged flower, but it is really a grey; and the same may perhaps be said of Alma. Some true florists, however, do not commend such artistic touches, while others of equally high standing adopt them. It appears to be a question of taste. A few other grey edges exceptionally fine at Slough are Alderman Charles Brown (Headly), excellent; Fletcher's Ne Plus Ultra, Lightbody's Richard Headly, and the same raiser's Robert Traill. It is in this section that the sturdy Col. Champneys comes and another striking flower of the same type—Royton's Royal Sovereign, also the grey or green Chapman's Sophia and Campbell's Confidence.

The selfs are represented by many beautiful varieties. The most striking of them all by its rich colour and noble truss is Charles J. Perry above noticed. Although it may possess a slightly faulty tube the flower has grand compensating advantages, and cannot willingly be dispensed with wherever Auriculas are grown. A flower of great merit is Campbell's Pizarro, but plants of this coveted variety cannot be retained at Slough until they reach their full splendour. Martin's Eclipse is bold and striking but the petals are somewhat rough, and the same remark applies to Sims' Vulcan, especially when it is judged in comparison with Turner's Clipper, an undoubtedly fine variety. Smith's Formosa is in excellent condition; it is a distinct and lovely self. Meteor Flag (Lightbody) is very fine and attractive, but is now passing its best condition. Spalding's Metropolitan is in admirable condition; in colour it is midway between C. J. Perry and Formosa, and is one of the most attractive in the section. Of the same type is Gibson's Mrs. Marsden, a grand flower. Mrs. Sturrock (Martin) is vigorous and extremely fine, and very rich and good is Headly's Petronella. A new large seedling self resembling Clipper is also highly promising. The varieties named are only a few of the more striking in this imposing section.

The Alpines yet remain to be noticed. Of these bold and brilliant flowers Mr. Turner is the greatest patron, as he has proved the most prolific raiser, of new and fine varieties. Both shaded and unshaded flowers are admirably represented, and both types are eminently worthy of cultivation both as florists' flowers and general decorative plants. One of the most commanding in this class is Mr. Turner's new variety Mrs. Llewellyn. The truss is remarkable for its size and contour; the centre is pale yellow, and the petals are maroon slightly shaded with violet. It is one of the finest in the collection. Queen Victoria of the same strain is also a splendid flower. Unique is stately in growth and is a shaded plum and violet flower of great merit. Napoleon III., rich yellow centre and maroon petals, is smooth and very fine, but not shaded. Dolly Varden, a shaded maroon and crimson flower, commands notice, as also does Topaz, which is very large and very rich; and Mrs. Thomson, the fine dark maroon flower that was certificated last year; it has a fine centre and is smooth and rich. Slough Rival, a very lively and cheerful flower, is highly worthy of culture. Nonpareil is a superior violet-shaded flower, and must not be overlooked; it is in the way of Elcho but surpasses it. Sensation is rich, smooth, large, and very good. King of the Belgians is one of the richest of Alpines; the flower is of excellent shape, with petals of great substance; colour glossy crimson. Mrs. Dodwell, Philip Frost, Spangle, Sydney, John Leech, and many others are all in excellent condition. These free-growing and striking Alpines are, as Mr. Weir says, good "for starting," and their satisfactory cultivation will lead their owner on to the possession of more delicate floral gems.

It now only remains to be said that these Auriculas, which have been cultivated so well and have been timed so skilfully to be at their best for the 25th inst., have been grown exclusively in frames. They were wintered in a pit and were subsequently removed to cold frames having various aspects suitable for advancing or retarding their flowers. When expanded many are placed under handlights in a shaded place, the pots standing on moist ashes—in fact, all the plants are placed on ashes and not on dry boards. In the north a heated house is probably an advantage for the cultivation of these flowers, and a suitable structure always enables the flowers being displayed to advantage, yet the condition of the collection at Slough affords evidence that a costly glass structure is not indispensable, but that a humble frame, good soil, and attentive cultural care are the only absolute essentials for growing Auriculas well and making their owners happy.

LOXFORD.

The grower of splendid plants, the winner of many prizes, the raiser of some new varieties of sterling merit, Mr. Douglas, has won a foremost place amongst contemporary cultivators of the Auricula. Mr. Whitbourn's is quite the most extensive and choice private collection in the south of England; and the owner of it, by the encouragement he gives to the cultivation of this and other florists' flowers, has done and is doing much to extend and improve their more general culture. This substantial patronage cannot but be highly appreciated by all who are interested in the resuscitation of flowers that have been too long neglected.

As at Slough, so in this well-known Essex garden, no elabo-

rate provision has been made for Auricula growing. The plants are grown in plain garden frames and an equally plain unheated pit. A light span-roofed greenhouse is occasionally utilised by affording accommodation to some of the plants when the flowers are expanding—accommodation, however, which, this year at any rate, has proved of questionable value, for the freshest flowers are in the frames. Allusion has been made to the decorative value of Auriculas. At Loxford their usefulness in this respect is very striking. In the span-roofed greenhouse there was early in this week a group of splendidly grown Auriculas, and in the same structure were equally well grown hard and softwooded greenhouse plants also in flower. In the same garden a small house, filled with cool Orchids in remarkably good health and flowering profusely, was also singularly attractive; but no flowers, judging them by their varied chaste and rich colours, their bold forms and clearly defined lines of beauty, produced such an imposing effect as the Auriculas. This is not the estimation of a specialist—a “one-idea’d” writer, but of one who looks at flowers as flowers, and who, when they are well cultivated, admires them all without prejudice to any.

The Auriculas bear away the palm at Loxford, and yet they have passed the zenith of their beauty—they are (and how disappointing the fact must be to their cultivator) fading on the eve of the great Show. That Mr. Douglas's name will be in the prize list at the Palace is certain; he will stage and stage well there, but not in such “form” as he could have done a week or ten days ago. Some of his best flowers are quite over, others have lost the bright gloss of pristine freshness, but will “just do” for staging; yet others, again, are worthy of Loxford and the Crystal Palace. Let us glance at a few of them. The term, however, is a misnomer as applied to that beautiful Auricula Taylor's Glory, for while the plants were grand a fortnight ago not a flower is now to be seen. The plants are literally “on the shelf” ripening seed which will yield flowers, let us hope, worthy of the parentage. The plants are very luxuriant, and the faded trusses and stout flower stalks tell how fine they have been.

Some others still beautiful are the following:—Kaye's Alexander Meiklejohn, very large, stout, smooth, and richly coloured—certainly one of the finest of the grey edges. Rev. F. D. Horner is another fine and very promising flower; it is almost certain to remain high on the list. Headly's George Lightbody is a very prince in its class, and is remarkably stout and fine. Hepworth's True Briton is admirably represented, as also is Cunningham's Mrs. Campbell, which is singularly pure and chaste. Beeston's Apollo and Hudson's Apollo are both extremely fine, and must be ranked amongst the very best in the green-edged section. Lancashire's Lancashire Hero is one of the finest in the collection, the flowers being large and altogether good. Although classed as a grey it can be made green by those who know how to do it; it is, however, more attractive as it is, the beautiful silvery wire rendering it very artistic. Heap's Smiling Beauty, one of the best of the whites, is in superb condition. The flower is very similar to True Briton, but the foliage in one variety is mealy, the other green. Cunningham's St. Augusta is a large and conspicuous flower, very attractive to the ordinary visitor, but will scarcely charm the educated eye of a real florist. Chapman's Maria is a fine and striking flower, distinct by the rich violet in the petals. Syke's Complete is a dainty gem pure and good, and the same remark applies to Summerscales' Catharina, a flower, however, perhaps more prized in the north than the south. Lady Sale is another good white in excellent condition. In fine contrast is Conqueror of Europe, the flowers being of extraordinary size, but fading. Campbell's Admiral Napier is a green edge of great excellence and admirably grown, and Cunningham's John Waterston deserves honourable mention for its triple possession—form, colour, and purity. Headly's Alderman Wisbey is a superior green flower, and another of Headly's Aldermen, Charles Brown, is of equal merit as a grey; this is, indeed, one of the finest in its class. Lady Sophia Dumaresque is a fair fresh flower, and Smith's Ann Smith is one of the purest in its class. Oliver's Lovely Ann and Gain's Lady Richardson are two fine varieties of darker hue (greens), and McDonald's Miss Arkley is noticeable not only by its attractive white-edged flower, but also by its beautiful mealy foliage. Others to be noticed are the best of all the green edges, Col. Taylor, a bright grass green of rare quality, and a seedling, the result of a cross between Robert Traill and George Lightbody. It is a beautiful silvery grey edge with a remarkably good and pure paste, but appears to be deficient in body

colour. It is a very distinct flower, and clearly reflects the characters of both parents, but whether it will prove worthy of them time and fanciers alone can tell. A parting word must be had on Col. Champneys. The plants and trusses have been grand, and some are good now. At the Palace this striking Auricula is sure to find many admirers.

A few selfs must be briefly referred to. Charles J. Perry is in splendid condition, and not less handsome is Campbell's Marquis of Lorne, a rich crimson flower, one of the best of its colour. Ellen Lancaster, Lord Clyde, and Mrs. Smith are fine varieties well grown; Vulcan is very good, Master Hole better, and Campbell's Pizarro perhaps the best of all; but a good word, a very good one, must be bestowed on Formosa, Topsy, Eliza, Meteor Flag, and Metropolitan, for all are excellent varieties excellently cultivated. Not much space is left for Alpines, not so much as they deserve, for the display of them is a fine one. The trio of seedlings raised at Loxford and certificated last year (Sylvia, Florence, and Prince) are noble flowers. Miss Reid, Beatrice, and Bronze Queen are also highly attractive. One more Alpine must be noticed before summarising—namely, Mr. Barlow's new variety Annie. This is a flower of much promise; it is very distinct, the ground colour being maroon purple shaded with very pale purple. It is of excellent form, and will take a good position in its class.

Now comes the summary of the best varieties at Loxford, or at least sorts that those commencing the cultivation of Auriculas can scarcely err in obtaining. Only half a dozen are selected in each section, and they are placed as well as possible in the order of merit.

Green-edged.—Col. Taylor, Page's Champion, Traill's Anna, Beeston's Apollo, Hudson's Apollo, and Admiral Napier.

Grey-edged.—George Lightbody, Alexander Meiklejohn, Alderman Charles E. Brown, Chapman's Maria, Robert Traill, and Col. Champneys.

White-edged.—Smiling Beauty, Taylor's Glory, Ann Smith, True Briton, John Waterston, and Ne Plus Ultra.

Selfs.—Pizarro, Charles J. Perry, Duke of Argyle, Topsy, Ellen Lancaster, and Formosa.

Alpines.—Diadem, Bronze Queen, Queen Victoria, Beatrice, Florence, and John Leech.

Small pots, thorough drainage, early potting, rich turfy loam, cold frames, and pure water (no liquid manure), are Mr. Douglas's landmarks of culture. Means more simple can scarcely be conceived, and results more satisfactory can hardly be desired.—J. W.

ROYAL BOTANIC SOCIETY.

APRIL 24TH.

As a minor Exhibition this was one of the best that we have seen arranged in the corridor and conservatory at this period of the year. The classes were well filled, and the nurserymen's groups—stove and greenhouse plants from Messrs. Rolleston and Cutbush, Roses from Messrs. Veitch, G. Paul & Son, and W. Paul and Son; choice ornamental plants from Mr. Williams; Azaleas from Mr. Turner, and Orchids from F. Philbrick, Esq., Q.C. (Mr. Heims, gardener)—were excellent. These collections, for which extra prizes were awarded, constituted the most important feature of the Exhibition, and were greatly admired by the visitors.

For twelve stove and greenhouse plants in flower in 12-inch pots Mr. Wheeler, gardener to Sir F. H. Goldsmid, Bart., Regent's Park, was awarded the first prize for very fair examples of *Imanophyllum miniatum*, *Azaleas Criterion* and *Iveryana*, *Ericas Victoria* and *Coccinea minor*, *Lycaste Skinneri*, *Odontoglossums Andersonianum* and *luteo-purpureum*, *Cypripediums villosum* and *caudatum roseum*, *Franciscea eximea*, and *Eriostemon densiflorum*. Mr. W. Roberts, gardener to W. J. Terry, Esq., Peterborough House, Fulham, was a very good second, having amongst others very well-bloomed plants of *Cattleya Skinneri*, *Odontoglossum Pescatorei*, and *Dendrobium chrysotoxum*. An extra prize was awarded to Mr. Joseph Bristowe, gardener to G. Campbell, Esq., Wood Fell, South Dulwich, for three large greenhouse plants and exceedingly well flowered. In the class for six Cape Heaths Mr. Wheeler was the only exhibitor, and was awarded the first prize.

In the nurserymen's class for nine Roses in pots Messrs. Paul and Son, Cheshunt, were the only exhibitors, and were worthily awarded the first prize for grand examples of *Souvenir d'Elise*, *Camille Bernardin*, *Cheshunt Hybrid*, *Perfection de Montplaisir*, *Marquise de Castellane*, *Dupuy Jamain*, *Madame Lacharme*, *La France*, and *Victor Verdier*, the plants carrying on an average fifty blooms each, and were excellent both in quality of flower and foliage. In the amateurs' class for six plants Mr. James, gar-

dener to W. F. Watson, Esq., Isleworth, was placed first with fair examples of Edward Morren, Elie Morel, La France, John Hopper, Souvenir d'un Ami, and Marquise de Castellane; and Mr. Bristowe third for some ugly standards. For six new Roses sent out in 1876 and 1877 Messrs. Paul & Son, Cheshunt, were the only exhibitors and received the first prize with Monsieur G. Tournier, Madame de Montchaveau, Duke of Connaught, Emily Laxton, Madame Baronne de Medin—all Hybrid Perpetuals, and Comtesse Riza du Parc, a rosy salmon-tinted Tea Rose.

A few of the more notable Roses exhibited were Duchesse de Vallombrosa, Souvenir d'un Ami, Mdle. Marie Finger, Madame Willermoz, La France, and Cheshunt Hybrid from Messrs. G. Paul & Son, and principally grown in 10-inch pots, a size very suitable for spring-exhibiting purposes; and in Messrs. W. Paul and Son's extensive collection Marie Van Houtte, Jean Goujon, Souvenir de la Malmaison, Magna Charta, Capitaine Christy, Fisher Holmes, and Duke of Edinburgh were the most noteworthy. In the collection of Messrs. Veitch & Sons Madame Willermoz and Madame de St. Joseph were very conspicuous. This firm also exhibited over forty exceedingly well-bloomed Clematises, Rhododendrons, Ghent Azaleas, three baskets of Gentiana acaulis, interspersed with *Acer polymorphum palmatifidum*, the whole forming a very effective group.

Azaleas were exhibited by Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham; Mr. James and Mr. Bristowe, who all staged very good collections, and the prizes were awarded in the order named. Mr. Turner, Slough, was the only exhibitor of Azaleas in the class for nurserymen, and was deservedly awarded the first prize. Cinerarias came from Mr. James, who was a good first with nine well-flowered examples; and Mr. J. Levesley, who was placed second with smaller plants. Mr. Ratty had the third prize. Mr. Knowles, gardener to H. Little, Esq., was the only exhibitor of Amaryllises, and received the first prize with Princess Dagmar, Olga, International, Rupert, Fairstar, and Mdle. Titiens. For nine Pelargoniums (open) Mr. James was the only exhibitor, and staged an exceedingly neat collection, principally fancies, for which a first prize was worthily awarded. The best collection of bulbous plants came from Mr. Roberts, who was awarded the first prize; and the awards for collections of Alpine plants went to Messrs. Roberts and Wheeler in the order named. Mr. Turner won the first prize in the class for twelve Auriculas, and Mr. Roberts was first in the class for six plants.

Mr. Walker, nurseryman, Thame, Oxon, sent three boxes of cut blooms of Roses, one box containing extraordinarily fine examples of Maréchal Niel, also a box of cut blooms of Geraniums and Anemones, for which an extra prize was awarded. Extra prizes were also awarded to Mr. Hooper, Vine Nursery, Bath, for a collection of Pansies; to Mr. Wheeler for a collection of plants; to Mr. Levesley, Isleworth, for Cinerarias; and to Mr. Ratty for a specimen Azalea.

Botanical certificates of merit were awarded to Messrs. Veitch and Son for *Adiantum Lawsonianum*, with finely and triangularly cut pinnae; for *Hæmanthus Kalbreyeri*, a very curious plant with scarlet flowers, the stamens and pistil of the same colour are even more conspicuous than the petals themselves; for *Dioscorea retusa*, a pretty trailing plant with Ivy-like leaves and drooping catkins; for *Rhipidoptera peltata gracillima*, a much finer cut variety than *R. peltata*, and for *Lastrea aristata variegata*; to Mr. B. S. Williams for *Dracæna Bausei*, Mrs. Bause, and Renardæ, also for *Ixora hybrida*, *Wallichia zebrina*, and *Glomeria jasminiflora*; to Messrs. Rollison & Sons for *Grevillea filicifolia*; to Mr. Turner, Slough, for Azalea M. Lefebvre; to Messrs. Paul & Son, Cheshunt, for H.P. Rose Mrs. Laxton; to W. Paul & Son for Rose Boieldieu; to Mr. Hooper for Pansy Frederick Perkins; and to Mr. G. Smith, Edmonton, for Gold-laced Polyanthus Admiral Hornby.

The weather during the earlier part of the day was especially unfavourable for visitors, and rain, more or less, continued until late in the afternoon, when a favourable change occurred, and a considerable company assembled to enjoy the Exhibition.

ANNUALS.

ANNUALS are everybody's flowers, but everybody who sows them does not grow them. Too often with the sowing of the seed the work of the cultivator ends, or nearly so; the plants are left unthinned to grow, or rather to kill themselves. They are worthy of a better fate, for annuals have a beauty of their own if it is permitted to be seen to its best advantage. The airy lightness of growth of many of these summer flowers constitutes one of their chief charms. When grown and grouped thinly their attractions are not only considerably enhanced, but are continued over a period thrice as long as when crowded so that neither light nor air can reach the interior of the plants. There is little more reason in sowing beds of annuals and permitting the plants to grow unthinned than in sowing beds of Lettuces and allowing the crop to grow in the same irrational manner. Types of two familiar annuals are represented in the

accompanying engraving (fig. 48). When thus seen in all their gracefulness none can dispute the beauty of these deservedly popular flowers, *Rhodanthes* and *Nemophilas*.

Rhodanthes are among the most admired of Everlastings. When well grown in pots they produce a charming display during the spring and early summer months. In the great exhibition of annuals arranged last year in the Royal Botanic Society's Gardens at Regent's Park by Messrs. James Carter and Co. none produced a more pleasing effect than the *Rhodanthes*, and thousands of pots of them are admirably grown for Covent Garden Market and for the adornment of metropolitan homes. All the varieties of these Everlastings are worthy of culture, and perhaps none more so than the old *R. Manglesii*; but the one figured, *R. maculata grandiflora*, is larger; and *R. Prince Bismarck*, which was prominent in the exhibition referred to, is richer; *R. atrosanguinea* is also, as its name implies, a very high-coloured variety, and for contrast we have the pure white variety *R. Manglesii alba*. The plants are usually grown and flowered in 5-inch pots. The seed is sown thinly in a compost of turfy loam and peat, and the plants are grown near the glass in light cool frames. The plants are thinned out to not less than an inch apart, and are treated much the same as *Mignonette*. There is only one important point that must be attended to in the culture of *Rhodanthes* in pots, and that is they must be watered with great care. Unlike the majority of plants they do not flourish well if the foliage is sprinkled, and it is generally better not to water the seed pots with a rosed watering pot, but the water should be applied carefully to the surface of the soil and underneath the foliage. By this simple precaution healthy foliage may be produced, which contributes so much to the attractiveness of the plants. If the plants are freely and frequently watered overhead much of the foliage decays, and the plants as a consequence are deficient in vigour, and their beauty is not only impaired but is much more transient than it would be if the plants were more healthily grown. Although the seed is sown in a compost of turfy loam and peat the lower half of the pots is filled with richer soil, of which decayed manure forms a considerable part—nearly or quite half, and the plants by rooting freely in this become luxuriant, producing good foliage and large and brightly coloured flowers. Not only are *Rhodanthes* in pots valuable for conservatory embellishment, but the flowers are particularly suitable for bouquets and vase decoration. The present is a good time for sowing the seed for a summer display; for producing plants for flowering in early spring the seeds must be sown in the autumn.

Nemophilas like *Rhodanthes* are both popular and pleasing. Amongst trailing annuals few are more extensively grown than these. Their colours are very varied, ranging from pure white through the different shades of lilacs to bright corulean blue, and even in the variety represented, *N. discoidalis*, almost to a glossy velvety black; but the most popular of all is the old and beautiful *N. insignis*. A dry and shallow soil this favourite annual cannot endure. It requires deep rich soil, and then if the plants are well thinned out so that each can produce side branches freely, and if the summer should prove a dripping one, the plants will continue growing and flowering quite through the season. In the ducal garden at Drumlannrig we have seen masses of corulean loveliness produced by this simple flower such as no other low-growing plant could produce. The seed cannot be sown too early; indeed in dry districts the best displays are produced by seed sown in the autumn.

At the present period for sowing seed of hardy annuals the merits of one of the loveliest of them all may be referred to—namely, *Ionopsisidium acaule*. The firm above referred to grew last year many thousand pots of this dwarf chaste annual, and the marginal lines of it were much admired both at the exhibitions at South Kensington and at Regent's Park. The seed was sown in April, and the plants were subsequently pricked-off into 4 and 5-inch pots, and produced floral cushions only a few inches in height and densely covered with small pale pink flowers. Rich soil and copious supplies of water are the essentials for growing this small yet charming annual successfully.

Another annual of low cushion-like growth, which is quite imposing when grown in masses, is *Saponaria calabrica*. Beds of this annual, covered with thousands of rich pink cruciferous flowers, are surpassed by few other flower beds during the summer and autumn months. This is emphatically a bedding annual, and as such it is worthy of being grown wherever a dwarf dense mass of pink is coveted. The seed should be

sown now where the plants are intended to flower, or the plants may be raised in a reserve bed and be transplanted in showery weather.

It may be reasonable to direct attention to a few other annuals adapted for bedding purposes—*i.e.*, those which not only produce bright masses of flowers, but which continue in beauty for a great length of time. The best pink bedding annual has been mentioned; the best for matching it as a scarlet is *Tropæolum King of Tom Thumbs*. This when procured true and grown well equals in effect scarlet *Geraniums*. The seed may be sown now where the plants are to remain, or, if

more convenient, they may be raised in the reserve garden and subsequently transplanted. A great advantage in connection with this bright annual is that slugs seldom or never eat the young plants. Another slug-resisting annual, and valuable as a bedding plant, is the dwarf *Convolvulus*; the best variety for a bed is *C. minor* var. *tricolor*. The flowers are rather small but extremely rich, and if the plants are grown rather thinly in rich soil they continue flowering for three or four months. Than a bed of this variety of *Convolvulus* few are more beautiful during the summer and autumn months; the flowers also keep well when cut and arranged in vases, and

Fig. 48.—RHODANTHE MACULATA AND NEMOPHILA DISCOIDALIS.

on this account are worthy of being grown in all gardens. For producing a yellow bed of a lasting quality *Tagetes signata pumila* is perhaps the best annual, but *Sanvitalia procumbens* is also free, bright, and continuous. The seed of these plants should either be sown in pots or in very rich light soil in a sheltered position in the garden, the plants being subsequently transplanted in their blooming quarters. The most lasting of white-flowered annuals of dwarf close habit is the white variety of *Saponaria calabrica*. Every year there are owners of gardens and lovers of flowers who desire to have distinct masses of colour in their beds, but who are unable to produce them by the orthodox bedding plants, hence a few annuals are named as substitutes, and which are certain to

give satisfaction if they are properly cultivated. By sowing seed of the annuals named it is quite easy to have beds of white, pink, purple, scarlet, and yellow. More than that cannot be produced by bedding plants that are increased by cuttings and raised under glass. A rich crimson bed may be had by sowing seed of *Linum grandiflorum rubrum*, but its beauty will not be lasting unless the seed pods are removed as the flowers fade. Another annual producing a glowing effect either in pots or beds is *Godetia Lady Albemarle*. When obtained true this is a very brilliant annual, but it is somewhat sportive, and should be grown rather closely until the flowers appear, when the inferior varieties can be weeded out.

Many more annuals are eminently worthy of culture, the

few named being selected on account of their special usefulness for particular purposes of decoration in the garden or greenhouse. Let them be grown thinly in rich soil; indeed, give them a chance to develop their characters and unfold their beauty, and they will not disappoint.

FLOWER SHOW AT EDINBURGH.

As was stated last week the Royal Caledonian Horticultural Society's Exhibition that was held at Edinburgh on the 10th inst. was both extensive and successful. Not a little of that success was due to the manner in which the collections of plants were arranged and the ample means that were afforded the visitors for inspecting them conveniently and advantageously. Frequently flower shows are either too crowded or too formal to be fully enjoyed—a result often unavoidable on account of the limited extent of the building in which the

exhibition is held. At Edinburgh the Flower Show Committee had an edifice at their command of unusual magnitude, and it is only justice to add that the taste of the managers of the Show was equal to the space at their disposal. They had ample scope and excellent material: hence the Exhibition was so eminently enjoyable. That the display was an imposing one is evident from a photograph which has been forwarded to us, and which we have had engraved. The Waverley Market is 336 feet long and, including the side galleries, 150 feet wide; the galleries, however, were not occupied, but the area of the building presented a remarkably attractive appearance. Much taste, says the authority from which we quoted last week, was displayed by the Committee and the active convener, Mr. David Mitchell, in the arrangement of the exhibits in the hall, and the general idea of an immense tropical garden was happily realised. The scene from the galleries was exceedingly fine—the gorgeous masses of blossom being relieved by the

Fig. 49.—FLOWER SHOW IN THE WAVERLEY MARKET, EDINBURGH.

cool greenery of the foliaged plants. Visitors, when tired of inspecting the many-hued floral gems set on the admirably arranged tables, found a new pleasure in promenading down the long avenues of waving Palms and feathery Tree Ferns, or, from the miniature Pine grove at the west end of the market, admiring the beautiful vista and the ever-moving groups. Round the colonnade in the centre of the hall were a series of broad tables, which were furnished by the prominent nurserymen and florists of the city. North and south of this were long lines of Palms, Tree Ferns, and Cycads, contributed by Professor Balfour, Regius Keeper of the Botanic Gardens, and Mr. James Cowan, Rosshall, near Glasgow. The latter collection was awarded the silver cup presented by Mr. David Mitchell, landscape gardener and estate agent, Comely Bank. North and south of the avenues were a series of tables, 40 feet long by 6 broad, on which were arranged with good effect the plants forwarded for competition, and on the south side was another row of tables containing flowering shrubs, the broad space between being broken up by a line of large Hollies and other hardy evergreens. The whole garden was enclosed, so to speak, with lines of splendid fruit trees—with the exception of the semicircular bay at the west end, which was occupied by the collections of Coniferae from the nurseries of the Lawson Seed Company and Messrs. Thomas Methven & Sons. In the former collection, which was awarded a special prize, there

were no fewer than 160 species and varieties of the Pine, and arboriculturists, who spent the greater part of the forenoon in studying the trees, confessed that they had never seen a more interesting group. Pendant from the cross beams overhead were large baskets containing trailing plants. When lighted up in the evening the hall presented a scene of oriental magnificence and rich harmonious colouring. It is gratifying to observe that the municipal authorities of the city gave their influential aid and co-operation in rendering the event so successful, and we should be glad if such an alliance of the horticulture of the district with the official central head of the town could be effected throughout Her Majesty's dominions. Town and country would alike be benefited thereby, and an art which contributes so much to the welfare and industry of the nation would be promoted. We congratulate our northern friends on the happy result of their labours, and we trust that we may have to speak approvingly of still greater gatherings of the same nature.

RASPBERRY AND AURICULA CULTURE.

MORE than fifty years ago my father formed a plantation of Raspberries, and ever since they were established they have borne large crops of very fine fruit, larger and finer than one ever sees in the London market. Many of the stools—perhaps

all—have been renewed, but the soil has never been changed. In my father's time the ground was never dug, but received an annual dressing of cow dung and coal ashes. The situation is cold and damp, the soil being strong loam.

My father was a successful *Auricula* grower. The plants were wintered in a cold pit, air being given at all times, except during severe frost. The glass was never covered even in the severest weather. When the first flowers commenced expanding in spring all the plants were removed to a little wooden structure open to the north-east; the roof projected about 18 inches over the front to throw off wet. In this cool position they remained in bloom a long time. My father was the raiser of that sweet little gem, *Miss Arkley*.—*CAMPDEN HILL*.

DIGGING AND MANURING.

MR. WILLIAM TAYLOR is evidently one of those gardeners who thinks for himself and has the courage of acting on his convictions, and also, which is of greater general benefit, of publishing them, even if they interfere somewhat with established notions. I have often thought that too much importance is attached to autumn manuring and winter digging. For years I have adopted the practice referred to, but generally as a matter of expediency. It was felt necessary to have as much ground as possible dug in late autumn and early winter, in order to facilitate work in the spring, which often presses so powerfully at that time. I have for a long time regarded that as the most important object of winter digging—the improvement of the land being considered as secondary.

Useful practical hints on land management may often be derived from intelligent kitchen-garden labourers. It was from an observant worker—a real “son of toil,” and successful in his calling, that I first received lessons on digging and manuring. The hints imparted to me were of precisely the same nature as those conveyed by Mr. Taylor on page 275. Both in dealing with heavy and light land I was taught that the practice of winter exposure was greatly overestimated. In the case of very strong land it was pointed out that two months of exposure of the soil during the hot sun and drying winds of summer was more effectual in promoting pulverisation than four months of exposure to the frosts and rains of winter. In proof of that the practice of the farmers in the neighbourhood was adduced, who could not reduce the soil to a cultivable state without “summer fallowing.” I have since found the principle to be sound when it has been applied to heavy ground in garden practice.

In the case of light soil the objection of my humble yet essentially practical tutor to manuring and digging in late autumn or early winter was based on the principle that the “nature” of the land was “washed out” by the winter rains. This idea may perhaps provoke a smile from semi-scientific, or rather pseudo-scientific, cultivators, but nevertheless there is much truth in it. At any rate my friend—for friend he was, and a near one too—had the courage of his convictions, and not once during a period of fifty years was his large garden of nearly an acre manured and dug in the autumn. So convinced was he that the practice of winter digging and manuring was not profitable in the moderately light soil of his garden, that I have many times heard him assert that if anyone would do the work for nothing in the autumn he would not have it done. Certain it is, it never was dug and manured until the spring, and equally certain is it that the soil increased rather than decreased in fertility after half a century of cropping.

The above represents the teaching imparted by an old tutor to a youthful pupil. Eventually the youth became a man, or rather arrived at that period of life when he had a strong opinion that he had attained to manhood. That particular feeling generally occurs shortly before a youth is out of his teens. I had then been gathering knowledge in fashionable gardens in distant counties, and had received new ideas from fashionable gardeners. I had also fortified myself with book knowledge, and had begun to talk rather freely of oxygen, nitrogen, &c., also on the absorbent nature of soils—indeed at that period I had a self-consciousness of knowing much about science and chemistry; but now, after many years of practice and of reading I confess to knowing very little indeed about those matters, but I know that the practice of spring digging and manuring light soils is right.

My first lesson was learned in this wise. I returned home full of science and self-conceit, and denounced the veteran's practice as wrong. Like a sensible man he did not attempt to argue the point with me, but (it was in the autumn) forthwith

placed several barrowfuls of manure in the middle of the garden. This he requested me to spread and dig-in. I dug it in deeply and formed the surface of the ground into ridges, and thus it was left through the winter. Towards the end of April or first week in May the garden was manured, dug, and planted as usual with Potatoes, the winter-dug portion having the ridges levelled-down and planted at the same time, but without any additional manure. I expected a great triumph, but instead sustained a crushing defeat. The autumn-dug square was visible throughout the growing season by the paler hue of the Potato haulm, and in the autumn was notorious for small Potatoes. That was a practical lesson that I have never forgotten. The difference so plainly shown by the two systems of management was not to be explained away, and I was driven to accept the fact that a portion at least of the virtues of manure can be washed into the subsoil and drains by long exposure of manured soil to the rains of winter.

Someone (Mr. Abbey, I think) has recommended the digging of ground in autumn without manure, and adding the enriching materials in spring, to be forked into the ground when dry at the time of cropping. I believe that in the case of many soils and crops, perhaps most, to be excellent practice and more economical—hence profitable, than applying the manure in the autumn.

Another matter worthy of attention that Mr. Taylor has mooted is having regard to the temperature of the soil at the time of digging. It is pretty generally admitted that it is bad practice to dig the ground during snow or in frosty weather, and very little of such work is done by those who read as well as work; but advantage is not taken to such a great extent as it might be of burying sun heat, and so warming the soil in the early days of summer. I have found the advantage of lightly turning over flower beds as often as the surface of the soil has become warmed by the sun by having thus raised the temperature of the soil very considerably before the time of planting the beds with tender plants. During sunny days in May it is not unusual to find the surface of the soil heated to 85° at mid-day, while on the following morning it is crisp with frost. Surely it is more advisable to turn the surface over and bury the heat than to permit 50° a day to escape by radiation. In securing early crops and in promoting the speedy establishment of tender plants the practice of digging in spring, when the surface of the ground is dry and many degrees warmer than the soil beneath, is a matter of considerable importance, as I think those will find out who practise it, say, in the case of a few beds intended to be planted with choice and tender flowers.—A NORTHERN GARDENER.

BOUVARDIA CULTURE.

THE few remarks on the culture of *Bouvardias* by “A SOUTHERN GROWER” at page 277 I think very good in some points, but I cannot agree entirely with the practice there detailed. In the first place I never increase my stock by cuttings from the young shoots, but by root cuttings in the following way.

When the plants have ceased flowering I cut them back close, gradually dry them off, and place them under the stage in a greenhouse or any other warm place where they can be kept free from drip. Then about the end of March I take a plant of each sort or more according to the quantity of stock I wish to raise, and wash all the soil away from the roots. I then select roots of about the size round of a hair pin or a shade less, and cut these up into pieces about $\frac{1}{4}$ -inch lengths, and place them rather thickly in a shallow box or pan filled with sand and covered very lightly. These pots are watered so as to wet the whole of the sand, and are then placed in a bottom heat of 75°. the atmosphere of the house being as near 60° as possible. No bellglass or shading is required, and not much water until the shoots begin to push up through the sand, and then they must be kept in a moist state. The young plants are potted off when they are 2 inches high or even a little less, as if they remain in the sand too long after they have made roots it will lessen the vitality of the plants considerably.

This mode of propagating the *Bouvardia* is far superior to that commonly adopted by taking off the young shoots, and the advantage is greater in all points. You can increase your stock more rapidly and produce finer plants, in fact there is as much difference in the growth as there is between a seedling *Geranium* and one struck from a cutting. When I have taken off all the roots I require from the old plants I pot them in as

small pots as possible, using rich soil, and plunge them in brisk heat, and they soon break strongly; but of course those that have been robbed of some of their roots will not be quite so good as the others, but I wash the soil away from the roots whether I want any root cuttings or not.

The plan described by "A SOUTHERN GROWER" of planting the *Bouvardias* out in a frame is very good, but I prefer planting them out in the open ground, that is if a sheltered and warm situation can be obtained. I plant them out 1 foot apart each way, and keep them well hoed and pinched back until the end of August, and then take them up carefully and plant them out on a bench in the greenhouse in about 1 foot of soil. By this method twice the number of flowers are produced, as the roots can be kept at a more even temperature. I think with your correspondent that from 60° to 65° at night a very good temperature, as the flowers do not come so fine nor last so long after being cut if they have been grown in more heat.

As regards the different sorts I have not much choice, as I think them all very good; but I give preference to *B. Vreelandii* as being the most free bloomer of the white sorts.—W. B.

HOUSE SEWAGE.

I HAVE from 1864 adopted the following inexpensive plan of draining and utilising house sewage by sub-irrigation. Drainage from the house is conducted by 6-inch brown stone-ware pipes in connection with the cesspool in the garden at the bottom of a steep incline. The cesspool is about 10 feet deep and 5 or 6 feet in diameter. Overflow pipes are laid about 18 inches from the top of the cesspool or at the level of the sewage, and from them adjoining are laid common drain pipes with bends or elbows to turn the corners at the end of each row of these pipes, which are laid in lines about 6 feet apart. These pipes are not cemented together, but simply laid end to end, so that the sewage as it passes through may be allowed to flow out of each pipe into the surrounding soil. They are laid at the depth of about 16 inches under the surface, so that the spade in digging does not disturb them. They have generally worked free about twelve months before they required to be taken up and cleansed from deposit, chiefly of earth washed into them by the rain through the joints. There is seldom any need of taking up more than two in every eight pipes, and a cane or length of iron hooping and flushing will cleanse the others without disturbing them. The rainfall on the roof of my house, of considerable dimensions, is conducted by pipes into the rain-water tanks, and the overflow of the tanks flushes the sewage drains from the house into the sewage tanks. The whole of the sewage is thus diluted with the rainfall from the surface of the roof, and there is great benefit to the vegetation without any nuisance; the soil when dug up is free from any sewage smell. This plan I prefer to the dry earth system, especially if carried out on the desiccation plan, or the expense of the A B C disinfecting materials. The sewage from the lodge and stables on a dead level is conducted from the sewage tank in a similar way into my garden round the borders about 18 to 20 inches beneath the ground, beds and grass plat, and in the drought of summer the grass shows greener where the pipes conduct it, and is burnt up at other places too distant from the sewage pipes. Thus the valuable portion of sewage, such as ammonia and its constituents in combination with phosphates and urates, esteemed for their stimulating properties in the growth of plants, is retained and used at less cost than the purchase of guano. The sewage tanks have not required to be emptied, and I expect never will, or for a long time, as all but sand will there be rendered soluble in time and pass into the ground; earth is a well-known deodoriser of sewage. In this system the sewage is distributed over a filter bed of 30 to 50 feet depth of earth before it can touch the springs in this district. A cottage having 20 square feet of garden ground of good light soil may thus utilise the sewage with much benefit to the ground, and no nuisance or fear of infectious fevers.—TWELVE YEARS' EXPERIENCE.

ANTS AND APHIDES.

THOUGH rather late in the field I would fain add to the notes already contributed by several correspondents a few sentences which may help towards a better understanding of the relation in which the above insects stand to each other, though there is and will be some obscurity remaining until

we have more entomological observers amongst our gardeners. Leaving for the moment the question as to whether ants, considered apart from their aphid-pursuing tendencies, are to be deemed hostile insects to horticultural pursuits, I will grant that there is no doubt that ants do carry to their nests and try to nurture there small colonies of aphides; but in so doing it is not probable that they much assist to increase in number these familiar pests. On the other hand, it has been proved that in some instances the ants have starved their prisoners, perhaps by accident, while ants of several species have been seen in the act of devouring juvenile aphides at large, hence we may presume they do so in their nests. Why should they not? They, like ourselves, need feel no scruples about milking their cows and also occasionally killing and eating their calves. Mr. Iggulden has pointed out a circumstance often overlooked, that ants pay visits to parties of cocci as well as to aphides, and of course it is from the like interested motives. If, indeed, it could be proved, as has been suggested by some theorists, that the honeydew or aphid secretion has a pernicious effect upon the leaves or stems of plants, then we ought to be grateful to ants, for they clear off a good deal of this substance. It is likely that the larger species of ants are the most inclined to play the carnivorous part, though the little ants so common in gardens and houses may be seen trailing along many insects living or dead.

Certainly the gardener is justified in adopting means to prevent the ants from multiplying largely, by effecting the occasional destruction of their nests, or by immolating them through sugary traps. They will haunt flowers at times in an unpleasant way, though even these they do not visit for the honey solely, but to seize upon minute insects. As a rule ants do not gnaw the petals, nor attack leaf or flower buds, and it is very supposable they may help to convey pollen from plant to plant.—J. R. S. C.

HOT WATER FOR PLANTS.

M. WILLERMOZ, in the French "Journal of the Society of Practical Horticulture," relates that plants in pots may be treated with hot water when out of health, the usual remedy for which has been repotting. He says when ill health ensues from acid substances contained or generated in the soil, and this is absorbed by the roots, it acts as a poison. The small roots are withered and cease their action, consequently the upper and younger shoots of the plant turn yellow, and the spots with which the leaves are covered indicate their morbid state. In such cases the usual remedy is to transplant into fresh soil, clean the pots carefully, secure good drainage, and often with the best results. But the experience of several years has proved with him the unfailing efficacy of the simpler treatment, which consists of watering abundantly with hot water at a temperature of about 145° Fahrenheit, having previously stirred the soil of the pots so far as might be done without injury to the roots. Water is then given until it runs freely from the pots. In his experiments the water first came out clear, afterwards it was sensibly tinged with brown, and gave an appreciable acid reaction. After this thorough washing the pots were kept warm. Next day the leaves of two *Ficus elastica* so treated ceased to droop, the spread of black spots on the leaves was arrested, and three days afterwards instead of dying the plants had recovered their normal look of health. Very soon they made new roots, immediately followed by vigorous growth.

NOTES AND GLEANINGS.

IN accordance with the newly issued regulations authorising the OPENING OF KEW GARDENS at ten o'clock in the morning on bank holidays, a considerable number of visitors availed themselves of the privilege during the forenoon of Easter Monday. A far greater number, however, entered the gardens during the afternoon when the weather was finer than in the morning. On days other than those named the gates will be opened to the public at the usual hour of one o'clock, gardeners and students in quest of information having access previously to that hour on application at the lodge near the chief entrance.

THE COOL ORCHID HOUSE at Loxford is now extremely attractive, principally with *Odontoglossums* and *Masdevallias*. Amongst the several varieties of *O. Alexandræ* we notice one of especial merit, the flowers being large and well formed and suffused with lilac. *O. cirrheum* is flowering with great

freedom, one variety now expanding being exceedingly fine; it promises to equal the richly and clearly spotted variety recently exhibited at South Kensington by Mr. Ollerhead. *O. Andersonianum* has a spike showing twenty-six flowers. The plants are in excellent health, and are mentioned because no fire heat is employed, nor was it employed in the winter unless the temperature fell below 45°. Since these beautiful flowers can be grown so well and so cheaply their cultivation ought to extend to many gardens which are destitute of them at the present time.

— THE NUMBER OF VISITORS who paid 2d. each for admission to the gardens of the Royal Horticultural Society at South Kensington on Easter Monday, were 6792, equal to £56 12s.

— THE approach to Mr. TURNER'S NURSERIES at Slough is now made extremely bright and cheerful by spring flowers. Wallflowers are in full beauty, as also are red and white Daisies, which have been planted by thousands. Early yellow *Violas* also contribute much to the floral display and contrast admirably with the purple *Aubrietia*, which is so valuable for early spring decoration. Many beds are planted with later-flowering *Pansies*, which will link the earliest flowers of spring with the summer bedding plants, and thus the display which commenced in March will be sustained throughout the season.

— DURING the festival of Easter many of the LONDON CHURCHES were extensively and tastefully decorated with flowers. Such flowers as *Rhododendrons*, *Roses*, *Camellias*, *Azaleas*, *Callas*, &c., when associated with wreaths of evergreens and formed into artistic devices, have an extremely pretty effect. The decorations at Easter if less extensive are more attractive than those at Christmas, and they are at the least equally appropriate. The custom referred to is gradually spreading in country districts, and in a few years will probably become general throughout the kingdom.

— OUR Poet Laureate, making an appeal to spring, writes thus in "In Memoriam":—

"Bring Orchis, bring the Foxglove's spire,
The little Speedwell's darling blue,
Deep Tulips dashed with fury dew,
Laburnums dropping wells of fire."

There are several species of *Orchis* that flower early; and the *Speedwell* intended is without doubt the *Germander Speedwell* (*Veronica Chamædrys*), which is a true spring flower. The *Tulip* and *Laburnum* are also appropriate to the season, but the *Foxglove* seems to come in out of place, for it is not in these southern districts to be detected in bloom much before July; and on the presumption that the poet was thinking of his Lincolnshire home-surroundings it might be thought the plant would be even later.—J. R. S. C.

— THE TULIPS at Messrs. Carter & Co.'s Forest Hill Nursery are now blooming. There are about fifty thousand bulbs of the finest varieties in the beds.

— IT is a long time since we witnessed such a profuse display of BLOSSOM IN THE CHERRY ORCHARDS of Kent and Buckinghamshire, and in other districts the trees are probably similarly beautiful. In the distance the orchards are masses of purity resembling mountains of snow, and, weather permitting, extraordinary crops of fruit must follow. The common lands also where Gorse prevails are brilliant with myriads of golden flowers, and the general aspect of the country smiles with beauty. This is emphatically the Eastertide of Nature—the great annual resurrection of flowers.

— AN American contemporary states that in consequence of the recent outbreak of *PHYLLXERA VASTATRIX* in Victoria, the Government of South Australia have decided to strictly prohibit the importation of Vines, Vine cuttings, Vine leaves, and Grapes. Arrangements have also been made for seizing fruit that may come to Adelaide packed in Vine leaves.

— STARCH IN PLANTS.—Botanists have hitherto held that all the starch in the chlorophyll cells of the leaves of plants is a product of the direct assimilation of carbon dioxide and water, basing this belief on the fact that the starch in these cells disappears when the plants are deprived of the power of assimilating carbon dioxide, but re-appears on their exposure to light in an atmosphere containing that substance. Professor Bohn of Vienna, in a recent number of the "Deut. chem. Ber.," throws some doubt on this conclusion by experiments he has made on the leaves of the Scarlet Runner. His results show that if the primordial leaves of this plant are shaded from light the starch at first entirely disappears; after

a few weeks, however, the chlorophyll cells of these shaded leaves show almost as high a per-centage of starch as the parts of the plant which have been exposed to light. These observations demonstrate therefore that starch can be formed in the leaves from matter which has already been assimilated and has entered into the leaf after its removal from the sunlight.—(Nature.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

STRICT attention is necessary to prevent injury to seed crops just appearing above ground. Slugs make sad havoc very often with Lettuces and other vegetables; there is no better remedy than to dust the plants late in the evening or early in the morning with quicklime. To check the ravages of birds dry soot or wood ashes dusted over the plants will usually be effectual. They should be dusted until they have made the second leaves, when birds rarely trouble them, but with Peas where sparrows abound the dusting with dry soot early in the morning whilst the haulms are damp will be necessary for some time. In some places the seeds of Turnips, Cauliflowers, and others of the Brassica tribe are taken when the crop is just appearing above ground, and unless they are protected by nets or dusted with quicklime or soot frequently are very much thinned if not destroyed. We have a complete army of birds, especially chaffinches, which are voracious seed-eaters, yet we do not suffer from their attacks, as we damp seeds with a few exceptions with water and coat them thoroughly with red lead before sowing. It gives a little extra trouble at sowing time, saving, however, much after trouble. Clear off spent crops of Broccoli, Kales, &c., and let the ground be well manured and dug or trenched preparatory to sowing with late Peas, of which a crop corresponding to the requirements of the family should be sown every ten days or fortnight up to the early part of June. We depend principally upon Dr. Maclean, Veitch's Perfection, Omega, Culverwell's Prolific, and Ne Plus Ultra for the summer and autumn supply of Peas. Sowing in trenches prepared for Celery, with the difference that though a trench is made it is filled up again to the level, is a good practice in shallow poor soils, but with those duly trenched and liberally manured is altogether unnecessary. Celery trenches for the early crops may be prepared. We take out the trench 18 inches wide and 10 to 12 inches deep, placing the soil in the space between two trenches—viz., 8 feet, and crop the ridges with a row of Lettuce upon each, sown at fortnightly intervals. The trenches have 6 inches of rich manure placed in them and well mixed with the soil. Earth-up and stake Peas as they require it. Make a sowing of Broad Beans, Radishes, Lettuces, Turnips, Spinach, &c., as required to meet the demand, keeping the hoe freely in use amongst growing crops whenever the weather is favourable. Proceed with the planting of herbs, which bring to a close as soon as possible. Sow at once a good breadth of Parsley for the principal supply in late summer, autumn, and winter. The scarcity of Parsley in winter is often due to the scant means taken to secure it. Sow Cauliflower for late summer use.

Forcing Department.—In bright weather the lights are better drawn off Carrots, Potatoes, &c., and constantly off Lettuces, Radishes, &c., in mild weather, having them in readiness, however, in case of frost. Celery intended for planting out early in next month should be well hardened, but gradually, as "bolting" is certain to result from a sudden check. Plants from seed sown early in March should be kept near the glass in a cool house or frame, so that they may grow up hardy and be in good order for pricking out next month in rich soil in the open ground. Cauliflower plants raised in cold frames from seed sown in February or early March prick out in warm situations in the open ground, also Brussels Sprouts from sowings made under glass. French Beans may yet be sown in frames or pits. The plants in bearing should be well supplied with water and liquid manure. Pot off Tomatoes; strong forward plants well hardened off are essential for outdoor fruiting. Shift Capsicums into larger pots. We fruit ours three in an 8-inch pot.

FLOWER GARDEN.

The means at the disposal of most gardeners are very inadequate to the growth and proper turn-out of the immense quantities of bedding plants requisite to make a successful display. A few beds well done are very much better than an immense breadth imperfectly filled until late in the season. Many makeshift appliances are called in requisition, and some of them of a very questionable character—sheltered places very often overhung by trees. The plants are brought from the glare of sunlight into shade, and are taken from darkness to light again; the foliage becomes brown and the plants stunted after planting out, taking a long time to recover. Still, until better accommodation is provided—glass houses, pits, or frames—temporary means of protecting the plants from spring frosts must be had resort to, such as turf pits and lattice frameworks covered with canvas or frigi domo. A lean-to house of this nature can be readily improvised where there is a wall, or a span-roofed structure may be speedily erected, the canvas lights being moveable so that the plants can have full

exposure whenever the weather is mild; but the sides should be closed, as drying winds are very prejudicial to the health of the plants. Whatever the means employed for hardening off the plants, ample protecting material should be at hand, so that they may be quickly covered in case of frost. *Verbenas*, *Lobelias*, *Petunias*, *Ageratums*, *Geraniums*, and plants of a similar character should be the first moved—strong plants large enough for planting out, which will afford an opportunity of forwarding other plants in a backward state in the structures from which they have been withdrawn. There is yet ample time to propagate cuttings of *Coleuses*, *Iresines*, *Petunias*, *Verbenas*, &c., and have good plants by bedding-out time. Seedling plants of *Lobelias*, *Petunias*, *Ageratums*, *Tagetes*, *Violas*, &c., are much better pricked out in cold frames in about 6 inches thickness of light loam and one-third leaf soil with a sixth of sand, at a distance of 2 to 3 inches apart, than coddled in heat. The lights should be kept rather close and shade be afforded until the plants are established, and by closing early in the afternoon and sprinkling overhead they will grow strongly and in due time may be lifted with capital balls. The different kinds of half-hardy annuals may be treated in the same manner, also *Pyrethrum Golden Feather*. Some, however, prefer to transfer the seedlings of this plant direct from the seed pans to its permanent quarters. For panel work in carpet bedding that plan is suitable, but for the edging of flower beds we find pricking-out advisable. *Alternantheras* may be struck very successfully in beds, the cuttings being inserted rather closely; if kept close and moist they soon root. They are the better, however, of a slight bottom heat. Cuttings of *Centaurea candidissima* strike freely in gentle heat, care being taken not to keep them too moist. *Mesembryanthemum cordifolium* variegatum may have the same treatment as *Alternantheras*.

Roses as yet unpruned should be no longer neglected. In exposed situations in the north it is not safe to prune until the latter part of April. The bloom is a little later, but safety for the young growths from spring frosts is thereby ensured. Complete the clipping of Box edgings, Ivy clipping, and the pruning of evergreen shrubs. This is a capital time for cutting hard in overgrown hedges of Yew, Holly, Privet, Box, Laurel, and Arbor Vitæ; also complete the planting of choice evergreen shrubs, though they may be shifted for some time yet, particularly Hollies. This is also the best time for transplanting Pampas Grass, it being desirable to move it with a ball, and in planting employ some rich vegetable compost. Water liberally in dry weather.

Aquatic Plants.—These are but little grown in gardens, but are coming to the fore, some of them being sweet and lovely, notably *Aponogeton distachyon*, which is so choice that no garden or greenhouse should be without it. Its flowers are white and deliciously fragrant. We have basins about 15 inches in diameter and about 12 inches deep, with 4 inches of rather strong loam at the bottom, in which the plants are planted, and by keeping them in the greenhouse from October to May, then placing them outdoors, we have flowers of this desirable aquatic all the year round, the basins only requiring to be kept full of rain water. In basins and tanks outdoors it is hardy in 12 to 15 inches depth of water. This is a good time to plant aquatic plants. *Nymphæas* take first rank, *N. candidissima* being very white in colour but not so strong-growing as *N. alba*. *N. odorata*, of which there is a smaller form—viz., minor, suitable for shallow basins, doing well in 15 to 18 inches depth of water. *Nuphar advena* and *N. lutea* have "cups of bright gold;" the plants like a muddy bottom with 2 to 3 feet depth of water. The *Iris pseud-acorus* is an useful aquatic, but requires to be kept within bounds. *Villarsia nymphaeoides*, *Typha angustifolia*, *Richardia æthiopica* (hardy in 18 inches depth of water) are desirable, as also are *Stratiotes aloides*, *Orontium aquaticum*, *Pontederia cordata*, *Hottonia palustris*, *Butomus umbellatus*, *Ranunculus aquatilis*, *Polygonum amphibium*, *Jussiea grandiflora*, *Alisma Plantago*, *Epilobium hirsutum*, *Lobelia Dortmanni*, *Sagittaria latifolia flore-pleno*, *S. sagittifolia flore-pleno*, *Myriophyllum spicatum*, and *Caltha palustris*, the variety *monstrosa* being truly gorgeous. Damp ground will accommodate the lovely *Menyanthes trifoliata* and *Lythrum roseum superbum*; and with percolating or running shallow water, *Sundew* (*Drosera rotundifolia*), on an island of peat all but submerged, covered with live sphagnum, in which the plants must be fixed. Foliage plants in aquatics are *Carex pendula*, *C. acuta*, *C. paniculata*, *Equisetum fluviatile*, *E. hyemale*, *Juncus conglomeratus* and var. *variegata*, *Thalia dealbata*, *Acorus calamus* and *A. graminea variegata*, *Caladium virginicum* and *Cyperus vegetus*.

FRUIT HOUSES.

Figs.—To have well-ripened fruit it is necessary to ventilate very freely whenever the weather is favourable, admitting some air constantly day and night, and lessening the supply of water when the fruit is fully ripening, and the atmospheric moisture, upon which and ventilation depend the colour and quality of the fruit. When the fruit is swelling the trees can hardly have too much water, especially those in pots, keeping also the atmosphere moist by sprinkling the house and syringing the trees twice a day. Liquid manure should be given to trees carrying a heavy crop of fruit. Attend frequently to the tying-in, thinning, stopping

the shoots at the fourth or fifth leaf of such as are required to form spurs, pinching the laterals succeeding at the first or second leaf, avoiding overcrowding of the shoots, which is fatal to good crops and fine fruit.

Pines.—Closing houses entirely in which young plants are in course of preparation for fruiting at a high temperature is conducive of soft, drawn, weakly growth, which should be carefully avoided by the employment of as little fire heat as practicable, husbanding the sun heat, and maintaining a moderate moisture in the house, by which means robust growth combined with sturdy habit is secured, the plants being in a position to obtain plenty of light and air. Sprinkling will be necessary occasionally, especially at closing time, but do not close entirely at a high temperature or a vapour bath will be produced, and syringe overhead about twice a week. No more artificial heat should be employed than to maintain the temperature at 65° or 60° by night, 70° to 75° by day. Commence ventilating at 75°, gradually increasing with the temperature to 85°, keeping it by day from sun heat at 85°, 90°, or 95°, but with abundance of air, reducing at 80°, closing for the day at that temperature. The bottom heat keep steady at 85°, or between 80° and 90°. Weak liquid manure may be applied with advantage to plants swelling but not ripening their fruit. Examine the plants regularly, and when water is required apply it liberally. If the plunging material settles down from the pots apply fresh to the surface to keep the pots from being acted on by the atmosphere prejudicially. In the case of large panes of glass and the sun very powerful a slight shade for an hour or two at midday will be of service, but with small squares of glass is not needful. As the fruit ripens both plant and fruit may be removed to a cooler house, which will enable its being kept sound for a lengthened period—longer at this time of year than any other. When the suckers of fruiting plants become large enough to handle screw out the hearts of those not required for stock; one, or at most two suckers, should only be retained to a plant.

Cherry House.—When the stoning is complete the fruit will commence colouring. The temperature should not exceed 65° by artificial means, and 60° to 55° by night, with a little ventilation, increasing it at 70°, and not allowing the heat to rise above 75° without full ventilation, closing at 70°, subject to the leaving of a little air on constantly at the top of the house. From commencing to colour until the trees are cleared of the fruit syringing must cease or the fruit will crack; but a good moisture should be maintained in the house by keeping the surface of the border moist, or if the trees are in pots damping the floors, &c., two or three times a day, avoiding, however, a stagnated atmosphere. Aphides must be kept under by fumigation; their presence for any length of time disfigures the fruit. See that the borders do not want for water, and liquid manure should be liberally applied to trees in pots.

PLANT HOUSES.

Greenhouse.—*Deutzia gracilis* though not a greenhouse plant is one of the finest for decorative purposes in spring, and is readily propagated by cuttings of the young wood taken off with a heel, inserting them in sandy loam around the sides of a 5 or 6-inch pot which will hold from nine to a dozen. Plunge the pots in gentle bottom heat and the cuttings will soon root, and should then be potted off singly in small pots and returned to the frame, shifting into larger pots as they fill the smaller ones with roots. Four or five-inch pots for the most vigorous plants will be sufficiently large the first year. The plants should be placed outdoors in July. Plants of this size are very useful for decorative purposes. It is desirable to keep plants that have been forced under glass until the growth is made, potting being done immediately after flowering, the plants doing well in turfy loam with a fourth of well-decayed manure or leaf soil. Outdoors the plants should have a sunny situation and be kept well supplied with water. *Spiræa japonica* when out of bloom must be hardened off, and when danger from frost is past the plants should be divided into two or more pieces and be planted out in rich moist soil, allowing a foot distance from plant to plant every way. *Lily of the Valley* if planted out in clumps of about twelve to twenty crowns after being hardened-off after forcing will be available for forcing again after a year's growth outdoors. *Rhododendrons*, hardy *Azaleas*, and other shrubs employed for forcing should after flowering be kept in a cool house for a time before placing them outdoors, and though they may form flower buds they are not nearly so good for forcing as fresh plants. *Schizostylis coccinea* kept in pots should now be parted. We divide plants in 9-inch pots into half a dozen pieces, and plant them out in rich light soil in an open yet sheltered situation, 18 inches apart every way, keeping them well supplied with water, lifting in autumn and potting. In a cool house they flower all the winter. Cuttings of *Eupatorium gracile*, *odoratum*, and *riparium* inserted now strike freely in gentle heat, and if potted and grown-on liberally make useful plants for winter flowering. The *Otaheite Orange* is very useful for winter flowering; the plants after flowering should be pushed in gentle heat and be well supplied with water. They should be syringed overhead, and are the better of slight shade. Any plants in a bad state at the roots, which will readily be apparent by the stunted and

unhealthy condition of the heads, turn out of the pots, reduce the balls, place in smaller pots, plunging in bottom heat if at command not exceeding 75°, and maintaining a warm moist atmosphere. Similar remarks apply to Oranges of all sorts. Double Primulas as they go out of bloom should be parted into as many divisions as the plants have crowns, securing to each division if possible a portion of stem, paring the end transversely with a sharp knife, and inserting singly in small pots in sandy loam with a little peat, surrounding the base of the cuttings with silver sand, keeping in gentle warmth and rather close until rooted. The old Double White should be grown in quantity, it being very useful. When rooted grow the plants on in cold frames through the summer. *Fuchsia serratifolia* vars. are valuable winter-flowering plants. Cuttings strike freely in a slight hotbed. Pot-off into 8-inch pots when rooted, return to the hotbed until established, then remove to a cold frame, shifting into larger pots as required. Old plants cut-in may be planted in the open ground in July, and be taken up and potted in October or before frost, placing them in a cold pit for a week or two, keeping them shaded if bright weather prevail, then remove them to the greenhouse, affording a light airy situation. Cut back *Acacias* and other New Holland plants as they go out of bloom, doing it moderately, as they do not break freely from the old wood. *Epacris* cut-in close, also *Cytisus* and similar free-breaking plants, encouraging growth by sprinkling overhead and keeping rather close. Ventilate Heaths very freely, and remove the seed pods from *Azaleas* as the bloom is cast.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (D. W. B.).—The "Horticultural Directory" can be had from our office, and free by post if 2s. 4d. are prepaid accompanying your full address.

MILDEW ON ROSES (John Walton).—If you dust thickly the leaves of your Roses with soot in the morning when the dew is on them, and allow it to remain for a couple of days, then washing it off by the aid of a syringe, you will find them much benefited.

MARÉCHAL NIEL ROSE (W. R. C. C.).—The probability is that your light sandy soil is also a poor one, and that the tree has not a very vigorous root-action. The best thing you can do is to remove the soil about the plant and replace it with a rich compost. There is evidently not sufficient vigour in the plant to enable it to develop its blooms.

PRESERVING ROSE PETALS (J.R.).—They only require to be dried by exposure to dry air, and then kept in a closely covered jar.

VARIEGATED LAUREL LEAVES (Idem).—They are not uncommon, and those you enclose are very irregular.

PERENNIAL FLOWERS FROM SEED (Inquisitive).—Sweet William, Pentstemon, Viola, Pansy, and *Ploceæ* seed should be sown immediately in rich light soil on a warm sheltered border; the Peony, Tritoma, and *Potentilla* seed to be sown in pots, which plunge in a gentle bottom heat and cover with a handglass or plant-protector.

PLANTING A SMALL CIRCULAR FLOWER BED (C. J. B.).—Consult your own taste. If you like *Geraniums* plant it with a mixture of choice kinds, so as to secure as much variety as possible. Here are a few inexpensive and good:—Master Christine, pink; Purty, white; Mrs. Musters, deep pink; Truth, salmon; Charley Casbon, scarlet; Mrs. R. Hole, magenta; Wellington, dark crimson; Theocritus, orange-scarlet; Edward Sutton, crimson; Triomphe de Stella, bright scarlet; Black Douglas, bronze foliage; Maréchal MacMahon, bronze foliage; William Sandy, golden tricolor; Lass o' Gowrie, silver tricolor. You may also have a ring of blue Lobelia or the yellow Golden Pyrethrum inside your edging of *Sempervivum*, and fill the centre with a *Geranium* or *Verbena* of your favourite colour. *Heliotrope* also makes a good bed, and has the additional merit of a rich perfume.

AUCUBA POLLEN (S. B.).—Almost any nurseryman could supply you with *Aucuba* pollen.

WHITE GRAINS ON GRAPE VINE (S. M.).—The small, white, egg-like substance which you have in such numbers on your Vines is a certain indication of high health. They will disappear as the growth becomes fully developed. You may fumigate with tobacco paper when the fruit is set. A severe frost will destroy the blossom of Filberts and Hazel Nuts.

VINE LEAVES (W. Lovel).—The Vine leaves are perfectly healthy. The small "crystal drops" are exudations of cellular tissue induced by the vigorous health of the Vine, and need cause you no alarm. The white on the upper surface has nothing to do with the Vine, and looks as if it was paint washed from the woodwork of the house and dropped on the leaves.

NURSERY GARDEN TENANT (Mary Hales).—The lease must be arranged between the tenant and landlord. There are no settled rules, and you had better consult an attorney to determine what is equitable.

MAKING HOTBEDS (F. Y.).—You may make hotbeds at any time of the year whenever you require the use of one. There is no particular season when they ought to be made in the same way as there is for the sowing of seeds.

HOT-WATER HEATING APPARATUS (D. H. W.).—To carry the flow and return pipes of a Pine pit through another house would of course affect the temperature of that house. You may avoid this by placing the pipes in a

tunnel beneath the floor, which, moreover, would facilitate any necessary subsequent inspection or search for leakage. If the pipes at the end of the Pine pit farthest from the boiler are 6 inches above it the circulation will be tolerably brisk; but we should prefer a rise of 2 feet if it can be managed, so as to ensure that prompt full circulation which is so important in Pine culture.

TO KILL SLUGS (Alpha).—The two best remedies for getting rid of slugs that we know of are unslaked lime in powder, and salt. The former you can use at any time by dusting it over your crops early in the morning when the slugs are about, and by repeating the operation whenever the previous application has lost its effect. Salt can only be used when the ground is bare, otherwise you are apt to injure the growing crop. Every time you ridge up or dig the ground give it a heavy dressing of salt, and this will not only kill the slugs with which it comes in contact, but will act as a manure as well.

GILDING IRONWORK (Subscriber).—We do not know that there is a gold paint used as a substitute for gold leaf for gilding ironwork. There is a bronze that is often used for that purpose, and which any painter can supply.

NAMES OF PLANTS (A. Boyle).—*Corydalis solida*. (W. P.).—*Arabis lucida variegata*. (J. S.).—Yes. It is the Fern you suppose. (Constant Reader).—*Ascia buxifolia*. (Subscriber).—1, *Polygala oppositifolia*; 2, *Thyracanthus rutilans* or *T. Schomburgkianus*; 4, *Justicia Eustachiana*. (Subscriber, Bagshot).—We cannot undertake to name plants that are not in flower.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF A BUTTER-MAKING DAIRY.

(Continued.)

NOTWITHSTANDING we have recommended earth floors in cow houses, some circumstances may arise which may make it injudicious to enforce them; we therefore think that the next best plan is to make floors of asphalt or concrete, with proper fall and gutter for drainage to tanks for the reception of the urine. With regard to finding accommodation for the dairy cows on the home farm, it often happens that there is an old barn which when not used for its original purpose may be easily fitted up as cowstalls and any thatched building of this kind answers well because it is warm in winter and cool in summer. If, however, a new erection is required we recommend brick walls with pantile roof, and if not laid in mortar the ventilation will then be good. The internal fittings should be with double or single ranges, according to the width of the building. If with a double range there should be a feeding path between. It is worth consideration whether the cows should stand in pairs with a stall division between each pair 7 feet in width, or whether they should be tethered singly in rows, the latter plan being less expensive in the cost of fittings. The former, however, is much better for the animals, because they feed separately without interfering with each other, nor can they turn round and drop their dung upon the part assigned for their bed. When stalls are constructed in this way cocoa-nut matting is sometimes used for a bed. There should be a pathway for feeding at the head and also behind the stalls for the removal of dung.

In again referring to earth floors, the advantage of them is direct as well as indirect, taking first the value of the manure obtained, which varies from 1s. 6d. to 2s. per cow per week whilst in the house, the quantity of excrement both liquid and solid being about 80 lbs. per day, and which certainly cannot be saved in so valuable and useful a form in any other way. There is also a saving in straw for litter to be considered. Then again, indirectly, the advantage of the animals living in a perfectly pure atmosphere is of the highest importance, not only as regards their health, but because we know that in foul air the germs of putrescence are formed, which attack both the food of the animals and also the milk whilst being taken from the cow. In fact, there is no substance or liquid to which the germs of putrescence so readily and surely attach as milk. These germs multiply in an almost incredible manner. They produce and reproduce upon the principle of the parasites, only much more rapidly. The milk then becomes impure; but this is often not discernible if used directly as milk, but when used for making butter it is often the cause of a bad article, which sometimes is quite unsaleable.

In referring to the duties of herdsmen or dairymen, attempts have been made to introduce a milking machine to supersede the

usual method of extracting the milk from the udder by hand, but without success in our experience. In milking great cleanliness should be observed, and it should be done quickly, always remembering that the last portion of the milk—the strippings—is the richest in cream. When this is not effectually drawn away it is often the cause of irritating accumulations in the udder, thereby shortening the milking period, and is often the primary cause of the loss of one or more quarters of the udder. It is likewise the cause sometimes of puerperal or milk fever at the time of calving. Cows, and especially young ones, should be treated kindly, because when they are irritated they will not give down their milk freely. Ill-tempered animals which often kick down a bucket of milk should not be conquered by fighting, but subdued by gentleness. In fact, if this system is adopted with heifers there will be no refractory cows. Cows when coming to the stalls to be milked should each have their regular place, and they will know it as well as the milkman. Wherever there is a sufficiency of pasture the cows should never be allowed to feed on the same ground two days in succession, but a change, although it may be only daily, is advisable; nor on any account should idle horses or colts be allowed in pastures to feed with the cows, although they may with advantage be allowed to feed in the dairy pastures in the absence of the cows, because they will often eat portions and bunches of grass refused by the cows. One of the great points in dairy management is to make sure of a herdsman who not only understands his work but takes delight in it, being fond of the cattle under his charge. He does his work with pride and pleasure, and with a man of this stamp it is quite amusing to notice how fond the cattle are of him; whereas, if unfortunately a herdsman only goes about his daily work with the view of earning so much money it may be taken for certain that he will himself require more looking after by his employer.

In our previous remarks referring to the cow houses we omitted to notice the necessity of providing calving boxes for the cows and accommodation for the bull. For the former it is essential that a box for a cow on the verge of calving should be roomy and not less than 12 feet by 12, the divisions to be not less than 5 feet high and close-boarded. The box to which we have previously alluded may well be provided for all the cows in the herd. It is only a question of expense, in which case no special provision of an apartment for cows at calving time will be required. An apartment for the bull, however, requires particular care not only in its placing but construction also, especially for animals of the Channel Island breed and their crosses; they often prove very refractory and sometimes vicious at an early age, and much more so than any other breed of cattle used for dairy purposes. It is first of all essential that the bull house should be placed in the most quiet part of the farm premises, where he will not be disturbed by the passing to and fro of the dairy cows. We in our own practice do not like tethering the animals, for when the cows visit them they are obliged to be let loose and tethered again; and in the case of some animals it is very dangerous for the herdsman to untie and tie them up again, many very serious injuries having sometimes been inflicted upon the man in charge. Our own plan is therefore to provide a double pen 13 feet by 13, and 7 feet high, with extra slabs up 4 feet high, under cover, and the same space outside, divided by a drawing door which can be moved backward or forward with a bar of iron by the man outside without entering the pens. In case of the visit of a cow, she enters the outside apartment and the door is withdrawn, just in the same way as when the pens are littered or cleaned out the inside or outside can be attended to without the presence of the bull. The arrangement for feeding is by a shutter to open outside immediately above the feeding manger; in this way the man in attendance need not ever be in the actual presence of the bull. Under this mode of management we have known pure pedigree stock of great value available for breeding purposes for years after they were entirely unapproachable by man, and obliged to be shot at last by the butcher. The mode of feeding a bull is important, as it should never be allowed a large quantity of roots or green fodder the same as allowed to cows, but a very moderate quantity, with a fair portion, say 3 or 4 lbs., of bean or barley meal daily, and water always accessible.

Let us now refer to the treatment of the cow before and after calving. We have always found in case a cow is allowed to go dry a long time before calving that they are apt to get into too high condition, in which case from fatty deposits internally milk fever often occurs at calving time. We never in our own practice could understand the necessity of letting cows go dry long before the calf was due, and have often milked the cows to within a few days of calving with the best results both to cow and calf. It often happens that the cow shows a very extended and inflamed udder some days before calving, in which case we have never hesitated to take a little milk once a day, and thus give the relief requisite. Again, to have healthy gestation, the cow always ought to have a moderate amount of exercise, which they get in summer, but in winter and house-feeding they get little or none, except in box-feeding, when they can move about freely and lie down with comfort, so essential to healthy pregnancy. In summer time when the flies tease the cows it is not our opinion that trees

in the pasture for shade are the best protection for them, for although we have splendid trees in our pastures we always preferred during the heat of the day to take the animals to the house, and being well ventilated in the roof we shut the doors and windows to exclude the sunshine and the flies also, for they always annoy most in the sunlight. The cows will then be comfortable if they get some green fodder and water, which is a great contrast to the disquietude they feel under the shade of trees, to say nothing of their manure being totally lost. We have on one property erected a shed in the pasture of an ornamental appearance, which is circular and divided into three compartments, to which the animals can resort for shelter or shade according to the time of year. The floor of the building is laid with dry earth or ashes to secure the manure, and renewed when required; and where the pastures are a considerable distance from the homestead the circular shed answers well without being an unsightly object if properly planned. Cows after calving will require particular attention for a few days, but more especially heifers with their first calf. We have always found it advisable before the calf can take all the milk to continue to take away a large portion of the milk, and leave the calf to clear out the udder entirely, which it can do with so much more effect than the milkman.

We cannot conclude our subject without some reference to the casualties to which dairy cows are liable. We have previously referred to the disease called "hoven," and which the veterinary profession know as tympanitis, or distension of the rumen or large stomach with gas. It is a disease which requires very prompt treatment, or suffocation may ensue from pressure of the distended stomach on the lungs, and often before medical aid can be called in. One remedy, and which should be resorted to when professional aid cannot be obtained in time, is to puncture the distended stomach with an instrument called the "trochar" or "stiletto," which is a sharply pointed and sheathed instrument, in the use of which the "stiletto" is withdrawn and the sheath allowed to remain for a short time, in order that the gas may escape. Those engaged in the management of dairy cows should make themselves acquainted with this instrument, and be able to use it in case of need. After the use of the "trochar," which any person after direction from a veterinary may use with impunity, medical aids may still be required, and some compounds of ammonia are the best adapted for use as a drench; but in the absence of this a full dose of gin is an excellent remedy. We defer any remarks relating to the rearing of calves, hoping at a future time to take up that subject specially.

WORK ON THE HOME FARM.

Horse Labour is now continued upon the land, and the season having been generally favourable but little time has been lost by wet days, the work of the farm is therefore generally in a forward state. Where the barley sowing is not yet finished the sooner it is completed the better, for it is sometimes delayed by the sheep not having finished feeding off the roots until a late period, the roots being required for sheep. This, however, is a matter for serious consideration on the home farm, seeing that we have now a succession of crops so perfect. The provision for sheep ought to be so arranged as not to delay the barley sowing beyond the middle of April. If the calculation is made of the loss consequent upon delay in the seed time for barley by holding over a root crop to a late period, it will be found to be a considerable deduction on the profits of sheep. This cannot be said to be successful management unless mangold is held on to be consumed together with early grasses, and supplemented by artificial food to counteract the effect of laxative vegetable food, such as barley or bean meal, mixed with the cut mangold. This counteraction is extremely desirable now more than at any other time of the year, for when ewes and lambs first enter upon grass feeding they often suffer from purging, the lambs in particular being often attacked with the "white scour," which is certainly the most fatal malady we have ever encountered. As it generally attacks them when they first go into the water meadows or early field grasses the shepherds should be prepared for it. This complaint often arises from a flush of milk, the ewes having more than the young lambs can take, hence an accumulation in the udder; the milk then becomes unhealthy and produces the white scour, therefore the ewes should be constantly noticed, and if their udders are distended they should be relieved. It always has been our constant practice whilst the lambs are young to daily examine the ewes, because a preventive is better than cure; in fact, white scour is rarely if ever cured unless it is observed at the outbreak.

The sowing of clover and grass seeds, either in the Lent corn or wheat, must not longer be delayed, and if circumstances have prevented the seeding when the corn was put in the clovers will come very well by sowing now. The ring roller is best to prepare for the clover seed, otherwise if the land be at all rough it is unkind for such small seeds, and they often get buried too deep. If the corn has vegetated and shows above ground, the ring roller followed by the chain harrow will do it no injury, and will sometimes be beneficial, especially if wireworms and other insect enemies are found attacking the corn.

The horse labour on the land now preparing for mangold should be continuous in fine weather, and we do not approve of much ploughing, we rather prefer the scarifier, and at this time of year one-horse labour with proper implements on anything but the heaviest land will be found quite sufficient. One-horse ploughs are now common, or the double-furrow plough with two horses attached. In both these cases in summer tillage much horse labour is saved without injury to the animals if they are of the right size and power, and well fed. It has long been our opinion that small undersized horses on the home farm are out of place, as you require more of them; there are more to feed, more lives at stake, more to shoe and harness, and we therefore advise that farm horses should not be less than 16½ or 17 hands high, with substance and power in proportion. Every horse can then take its part of the work on the farm in one-horse labour; in fact, this one-horse work on the home farm where only a few are kept is the only economical substitute for steam culture, and is the only way by which horse power can be reasonably compared with the advantages of steam power, so much in use upon the larger farms.

Hand Labour.—The women now must be employed on various work on the home farm, as there is much work which it will not pay for employing men to carry out. On various farms we constantly employ women, such as weeding, couching, &c. In some districts, however, women labour is not available, as they won't work in the fields. Now this when it occurs is often the farmer's own fault, because generally women can be found for farm work if they are constantly employed winter and summer, wet and dry weather, and unless they are found constant work and become accustomed to outdoor occupation they cannot bear the change continually from indoor occupation to outdoor work in the fields. It is not reasonable to expect women to be always ready for work in the fields when it suits the farmer to only occasionally employ them; on the other hand, we contend it will answer the farmer's purpose to employ some women constantly. There is various work continually requiring attention on the home farm, in the fields in dry weather, and also at the homestead in showery weather, and it only requires judicious and thoughtful arrangement to successfully employ women on the farm. Weeding is now the most urgent work for them, which just at this time is very important; and although men are often employed in this work they seldom do more than women can. For much of the work connected with sheep and cattle feeding we constantly employ women, such as preparing mangolds or swedes for the cutter and other light work.

ARTIFICIAL INCUBATION.

(Continued from page 253.)

MANY as were the furnaces in France which might in M. Reaumur's opinion be turned to account for incubation—those of bakers, confectioners, glass and iron workers—still he recognised the fact that in many parts of the country no such appliances existed, and if artificial incubation was to become a branch of national industry it must be more generally practised. He thereupon set to work to make experiments in hatching in hotbeds. So unwearied was his diligence in this work, and so instructive were his failures and successes alike, that at the risk of being wearisome we shall attempt to give a summary of some very long and rather tedious chapters in which he relates his experiments and their results.

The idea was first suggested to him by accounts of old writers, though all of them seemed ignorant of their subject. Aristotle and Democritus, Gesner and Aldrovandus alike, evidently related that of which they had no personal experience. Had any of the many writers who have mentioned the practice, he says, "experimented thereon he would not have failed to assure us of the fact, and would not have forgotten to relate the difficulties which he had to overcome. Apparently he must have encountered at least a part of those, which in spite of experiments made with incessant care, and which have almost exhausted my patience, have prevented my reaching the point of hatching a single chicken after the expiration of almost a year." There are certain facts about the nature of dung beds, he says, to be remarked on before trying them. One is that their heat increases for several days after it has been made up, so that at certain times the hand cannot be held in one: indeed his first batch of eggs, though placed in a vase, were all cooked. Another is that the heat varies much at different depths. After it has come to its highest point it decreases in the same ratio that it has increased. The temperature for incubation is one of the intermediate degrees of heat in both the increase and decrease: could, then, this intermediate temperature, which would naturally last barely a day, by any means be protracted for three weeks? M. Reaumur believed it an absolute impossibility; but it occurred to him as feasible to heat a kind of oven by means of a hotbed—i.e., to surround a large hollow space with it in such a way as to heat the internal air to a regulated temperature.

His first trial was thus conducted: He made up two small hotbeds with a narrow interval between them, the ends of which he thickly filled up so as to leave a cavity of about 3½ feet long;

over this was put a cover of two boards, which could be either close or separated for the regulation of the temperature. Rough as was the apparatus it had all the points essential to success. It was placed under a shed to protect it from rain. For some days the temperature continued too high, though the boards were kept open. When it descended to the desired point he put in two hundred eggs; some of them were placed on shelves, some in baskets. Every day one was broken, and it was evident that the germ was duly developing. A second hotbed was now set up for fear the heat of the first might fail; but subsequent experience showed this to have been quite unnecessary, and that it is quite possible to keep up the temperature of the same bed for several periods of incubation up to six months. In this first batch and in many that followed all went well up to the eighth or tenth day, but then came a change. An odour soon announced that some were spoilt, their shells cracked: they were discovered and removed. More followed in the same way, and at last all were found to be bad and their contents to have turned to a black or green fluid. This was the end of one experiment. M. Reaumur was not daunted by the failure, but considered much gained in that certain chickens had duly developed up to the fourteenth or fifteenth day. He tried another batch of eggs and duly placed some fresh-laid in the pit, but the result was little more satisfactory, though in some cases all went well till a day or two before the due time of hatching. For two months and a half he continued unsuccessfully to repeat the same experiment. After an interval of rest he began again, and for three more months tried hotbeds of various construction. At last he made the alteration of putting the bed in a stable with six horses. It was a wet season, and the whole apparatus, eggs included, seemed bathed in moisture: still for seven or eight days they duly developed. After a time this moisture subsided and there was no appearance of steam in the receptacle for the eggs, yet they were added in exactly the same way. For two months and a half more did he daily put in fresh eggs, but with no better result. From a series of observations he came to the conclusion that the damper the place was the earlier did the eggs go wrong, and in the end that the foul exhalations from the dung caused the death of the embryo. A remedy for this occurred to him—viz., to surround the egg chamber with well matched boarding, through which the warmth of the hotbed might penetrate but not the exhalation. A still simpler expedient was to put a barrel in the bed. This he so arranged that its top was 3 or 4 inches above the dung. Its lid had a large square hole in the centre with its own removable cover, and eight smaller holes capable of being filled up with corks: these were the regulators of the temperature. Lastly he had some round baskets made an inch or two less in diameter than the tub and varying in depth, some being made for one layer of eggs, some for two. To begin with, he put about two hundred eggs into these baskets, the lowest of which was a few inches from the bottom, the highest a few inches from the top of the tub. They were kept in position by various means which he thought not worth relating. The success of this ingenious device was complete, and at the end of twenty-one days a number of chicks duly came out. Several more tubs were brought into use, and M. Reaumur had for some time the daily pleasure of watching large and successful hatches.

His summary of the knowledge gained through these experiments is instructive, and we will give it in his own words translated:—"After having reached the point of teaching the person who had charge of the hotbeds to maintain constantly a proper temperature, and after having been perfectly satisfied with the regularity of that which he maintained, I was astonished at the fact that the chickens from many batches of eggs were not more fortunate; in fact that all, or almost all, perished. The thermometer could not show me the cause of their death, yet another instrument might have done so, one used by physicians too, and which they have long desired to bring to the same standard of perfection that the thermometer has attained—viz., the hygrometer, or the instrument which gives a kind of measurement of the humidity of the air in which it is placed. At times the air of the egg chamber was too moist, as proved by drops of water hanging from the cover. This is prejudicial to the chickens within the egg; in fact, unpleasant experiences many times repeated have revealed the fact that even when there is not sufficient moisture in the egg chamber to generate drops on the walls and sides, still it may be filled with a vapour destructive to the embryo. Before I was persuaded of its existence, before I discovered how baneful it was, and before I devised means of preventing it forming and resting in the egg chambers, it was my fate to lose many successive batches of eggs."—C.

THE BIRMINGHAM POULTRY EXHIBITION SOCIETY.

THE Committee met at Bingley Hall on the 15th, under the presidency of Mr. G. C. Adkins, to revise the prize list for their department of the Show to be held in December next. Several alterations were made, and a few fresh classes were introduced.

without increasing the total amount of money to be granted by the Council, a saving having been effected by withdrawing one prize from those varieties which have not been shown in sufficient numbers to justify the continuation of the sums hitherto allotted to them.

No change whatever was made in the classes for Brahma Pootras; but in Dorkings the prizes which have up to the present time been awarded to "Coloured, except Silver-Grey," will be given to "Greys, except Silvers." As Cuckoo Dorkings seem to be coming into favour again a class has been added for them, with prizes of £2 and £1 for cocks, and the same amount for hens, and this variety will also compete with the Whites for the £4 cup. In Black Cochins the value of the cup was increased from £3 3s. to £4, and each of the four second prizes was increased from 10s. to £1. In Malays four third prizes of 10s. were added, and an additional £3 cup given, so that there is one for the cocks and another for the hens, instead of both sexes competing together for the preference. The experiment of separating the old birds from the young ones in the Hamburg classes having failed, there will for the future be no separate class for either cockerels or pullets; but the second prizes will all be increased to £1, and the third prizes of 10s. will be added. The class for Silkies having proved to be very unremunerative it will be discontinued; but new classes will be formed for Sultans, with prizes of £2, £1, and 10s., and for Minorcas, with £2 and £1. The class in Game fowls for Whites and Piles will in future be for Piles alone, and that for Black and Brassy-winged, except Greys, will be for "Any other variety." By this change it is hoped to obtain specimens of the rarer kinds of old English Game fowls. The second prizes in the selling classes for any other variety of fowls are increased from 10s. to £1.

A new class is opened among the Ducks or Ornamental Water Fowls for Cayugas, with prizes of £2 and £1, and this variety, as well as the Black East Indian, will in future compete with the Mandarins, Carolina, Call, and other Ducks for the £3 cup.

In Pigeons the class for any other variety of Muffed Tumblers is this year divided into two—one for Saddles and the other for Badges, with prizes of £2 and £1 for each. Considerable alterations have been made in the Dragoon classes, of which there are now six for old birds and two for young ones, with prizes of £2 and 10s. each, and two £3 cups. The classes for old birds are for Blue cocks, Blue hens, Silvers, Blue Chequers, any other colour cocks, any other colour hens; and for young ones, Blue or Silver, Red or Yellow, and any other colour. In Antwerps, too, the arrangement has been altered. There are now six classes instead of four for Silver Duns, Blue or Blue Chequers, and Red or Red Chequers, in old birds, and the same for young ones, with prizes of £2 and £1 in each class.

BATH AND WEST OF ENGLAND SHOW.

WE have received a schedule of the Bath and West of England Society's Show, to be held at Oxford in June next. Coming as it does as one of the first shows in the season, it has for a long series of years past been a matter of peculiar interest among poultry amateurs; and the competition in the Pigeon classes is also generally good.

All entries must be made on or before Wednesday the 1st of May next, and every entry must be at the showyard before ten o'clock in the evening of Saturday the 8th of June next. The poultry will be exhibited as single birds, excepting Bantams, Ducks, and Geese, which will be shown in pairs. There are sixty-four classes for poultry, the first prize in each being £2, the second £1, with an additional third prize of 10s. in each of the distinct variety classes. Besides these premiums two silver cups value five guineas each will be awarded respectively to the best cock and hen exhibited.

There are twenty-one classes for Pigeons with prizes of £1 and 10s. to each class, besides which the flying or homing class has a third prize allotted to it. The Pigeons exhibited in this latter class, after being judged in the pens, will be liberated on the morning of June 10th, and to secure their prizes must be returned to the show before ten on the evening of Tuesday, June 11th.

The excellence of the arrangements and the careful attention to the management of the birds shown will be in the hands of the same experienced amateurs as have so well conducted it in former years.

VARIETIES.

IN 1873, on the representation of the Bombay Chamber of Commerce, who urged that the weight of the export duty and the length of the sea voyage practically disabled Indian wheat from successfully competing with any other country in the English market, except, perhaps, California and Australia, the Government of India freed Indian wheat from all duty on export. Since then, aided by various other circumstances, particularly the shortened transit through the Suez Canal, and recently the state of exchange, and perhaps, to some extent, the condition of eastern Europe, the increase in the trade has been very great. This may

be seen from the figures which in 1871-72 show an export of 687,090 cwt., whereas for the ten months only of 1876-77 the total was 4,885,290 cwts.

WE learn that the stand of Messrs. Sutton & Sons, the Queen's seedsmen, and seedsmen by special warrant to H.R.H. the Prince of Wales, at the Paris Exhibition of 1878, will be one of the most exhaustive displays of horticultural and agricultural produce ever brought together. We understand that there are more than two thousand models from nature of the principal kinds of agricultural and horticultural plants and roots, in addition to nearly five hundred specimens of permanent pasture grasses, as well as eight hundred samples of seeds. The display occupies a large portion of one of the extensive buildings erected at the special desire of H.R.H. the President for illustrations of English agriculture, and it is already in such a forward condition that it will be quite ready for H.R. Highness's private view on the 26th of April. Not only inside are Messrs. Sutton making such an extensive display, but in the Exhibition grounds nearly three acres have been sown with Messrs. Suttons' grass seeds, which are now rapidly forming a beautiful sward. In addition to grass seeds Messrs. Sutton have supplied a great quantity and variety of flower seeds, which will be transplanted during the summer in various parts of the Exhibition grounds, and a most brilliant effect is anticipated.

TO cure scab in sheep rub some plain petroleum with a sponge three times a week; this I learned from a very large Australian sheep-master, who always used it. Dogs can be cured of mange in same way. This I know from personal experience.—N. S. (in *Irish Farmers' Gazette*.)

NOTWITHSTANDING the political agitation in Spain its agriculture is not neglected. We have received the April number of the "Journal of the Valencia Agricultural Society," and it contains some useful information.

MESSRS. EDWARD WEBB & SONS, the Queen's seedsmen of Wordsley, Stourbridge, we are informed, contribute an extensive stand at the Paris Exhibition, consisting of specimens and beautifully finished models of Webb's improved varieties of agricultural roots. Vegetables, flowers, and agricultural and horticultural produce generally will be exhibited, also a large and neatly arranged display of specimens (in the straw) of the noted cereals—wheat, barley, black oats, white oats, &c.—raised by this eminent firm of seed-growers at their extensive and model seed farms at Kinver Hill, together with upwards of one thousand bags of various kinds of seeds for the farm and garden, and a collection of three hundred dried specimens of the natural grasses. The firm will also exhibit many other articles connected with the agricultural and horticultural seed trade, all admirably arranged, the whole forming a remarkable museum, which every visitor should inspect. We learn that a large portion of the Exhibition grounds at Paris have been sown with Webb's grass seeds, which have attained a high reputation all over the world.

THE great dairy interest in America is, writes Mr. E. W. Stewart in the *New York Rural*, represented by 11,000,000 of cows, absorbing a capital of \$500,000,000 in this stock, and the land necessary to maintain these cows cannot be less than fifty millions of acres, which at even \$20 per acre represents a value of \$1,000,000,000, upwards of twenty and a half millions of pounds sterling. Messrs. Horr, Warner, & Co., of Wellington, Ohio, are the most extensive butter makers known. During the season of 1877 they churned over 400,000 lbs. of butter, and this year they are using the milk of 9000 cows.

BEEES DYING.

IN response to Mr. Pettigrew on this subject, all my hives are doing well. The five stocks I have kept since the autumn of 1876 are in straw skeps. Last year only three of them swarmed. The bees of these top swarms I added to the parent hives about September. None of the five had supplies enough for winter, so ere I began to feed I reasoned thus—If they get no help they will all die, if they get only partial help they will also likely die, besides cause me a bit of trouble as well as the expense of feed I give them, and so I concluded it to be best to feed liberally if at all. I gave the five 100 lbs. of the best sugar, adding two pints of water to each 8 lbs. of sugar, and after boiling about the half was put into flower-pot saucers so large that the bees got their share at about two different feeds. An extra eke was put on to hold the saucer, and plenty of thin slips of wood to keep the bees from drowning. This was done about the end of September. I found on examining them about the middle of this month that there were six seams of bees in each of the hives but one, which had five. I am quite satisfied there was never a winter that so little attention was paid to them as this one, never having looked into them for about six months. I never lost but one hive by death, or rather by the death of the queen, never lost one by hunger, or fighting, or disease, nor lost a runaway swarm, was never aware of one running away.

"B. & W." on February 1st, 1877, speaks of queens occasionally

leaving hives at other times than to mate with the drones. I can prove this to be the case. The hive that is spoken of above was lost to me through the queen going out and not finding her way back again. I found her dead at the door. That was in the month of January or February, 1877.—JAMES SHEARER, Cairnie, Aberdeenshire.

THE HUSBANDRY OF BEES.

(Continued from page 312.)

THE bees gather not till July, for then they be discharged of their young, or else they are become now strong to labour; and now sap in flowers is strong and proud by reason of time and force of sun; and now also in the north (and not before) the herbs of greatest vigour put forth their flowers, as beans, fennel, burrage, &c. The most suitable weather for them is heat and drought, because the nesh bee can neither abide cold or wet, and showers (which they well foresee) do interrupt their labours unless they fall in the night, and so they further them.

DRONES.—After casting time you shall benefit your stocks much if you help them to kill their drones, which by all probability and judgment are an idle kind of bees and wasteful. Some say they breed, and have seen young drones in taking their honey, which I know is true. But I am of opinion that there are also bees which have lost their stings, and so become idle and great; there is great use of them. "*Deus et Natura nihil fecit frustra.*" They hate the bees and cause them cast the sooner; they never come forth but when they be overheated; they never come home laden. After casting time, and when the bees want meat, you shall see the labouring bees fasten on them—two, three, or four at once, as if they were thieves to be led to the gallows, and killing them; they cast them out and draw them far from home as hateful enemies. Our housewife, if she be the keeper of her own bees (as she had need to be), may with her bare hand in the heat of the day safely destroy them in the hive's mouth. Some use towards night in a hot day to set before the mouth of the hive a thin board with little holes in it, at which the lesser bees may enter, but not the drones, so that you may kill them at your pleasure.

ANNOYANCES.—Snails spoil the bees by night like thieves. They come so quickly and are so fast that the bees fear them not. Look early and late, especially in a rainy or dewy evening or morning. Mice are no less hurtful, and the rather to hives of straw, and therefore coverings of straw draw them. They will in either at the mouth or shear themselves an hole. The remedy is good cats, rat's-bane, and watching. The cleanly bee hateth the smoke as poison, therefore let your bees stand nearer your garden than your brewhouse or kitchen. They say sparrows and swallows are enemies to bees, but I see it not.

Most hives perish by winter's cold than by all other hurts, for the bee is tender and nice and only lives in warm weather and dies in cold, and therefore let my housewife be persuaded that a warm dry house before described is the chiefest help she can make her bees against this and many more mischiefs. Many use against cold in winter to stop up their hives close, and some set them in houses, persuading themselves that thereby they relieve their bees. First, tossing, moving is hurtful; secondly (in houses), going, knocking, and shaking is noisome; thirdly, too much heat in a house is unnatural for them; but lastly and especially, bees cannot abide to be stopped up close, for at every warm season of the sun they revive, and living, eat, and eating must needs purge abroad. In her house the cleanly bee will not purge herself. Judge you what it is for any living creature not to disburden nature. Being shut up in calm seasons lay your ear to the hive and you shall hear them yearn and yell as so many hundred prisoners, therefore impound not your bee, so profitable and free a creature.

TAKING OF BEES.—Let none stand above three years, else the combs will be black and knotty, your honey will be thin and uncleanly; and if any cast after three years it is such as have swarms of old bees kept all together, which is a great loss. Smoking with rags, rosin, or brimstone many use; some use drowning in a tub of clean water, and the water well heaved will be good botch. Draw out your spels immediately with a pair of pincers lest the wood grow soft and swell, and so will not be drawn, then must you cut your hive.

STRAINING HONEY.—Let no fire come near your honey, for fire softeneth, weakeneth, and hindereth honey from purging. Break your combs small when the dead empty combs are parted from the laden combs into a sieve borne over a great bowl or vessel with two staves, and so let it run two or three days. The sooner you run it up the better will it purge. Run your swarm honey by itself, and that shall be your best. The older your hives are the worse is your honey.

VESSELS.—Usual vessels are of clay, but after wood be satiated with honey (for it will leak at first, for honey is marvellously searching, though thick, and therefore virtuous), I use it rather because it will not break so soon with falls, frosts, or otherwise, and greater vessels of clay will hardly last.

When you use your honey, with a spoon take off the skin which

it hath put up. And it is worth the regard that bees thus used, if you have but forty stocks, shall yield you more commodity clearly than forty acres of ground, and thus much may suffice to make good housewives love and have good gardens and bees. *Deo laus.*

[From an old book called "A Way to Get Wealth," printed by T. B. for Hannah Sawbridge at the Bible on Ludgate Hill, London, 1683.—A KILKENNY BEE-KEEPER.]

OUR LETTER BOX.

AN INJURED LARK (J. H., Glasgow).—The prostrate state of your Lark has, no doubt, been brought about through injury and bruises it sustained whilst fluttering about the room in which it was suddenly let loose. Whilst the bird remains in its helpless condition let it be kept quiet, which may be aided by covering over the cage with some light material. Place some soft hay upon the cage bottom, besides a fresh grass sod for the bird to rest upon. So place the usual food that it may be of easy access. A few mealworms may tempt the invalid, but as you say your Lark prefers egg so continue the diet. In a few days the bird may regain strength. The Lark certainly must have been much frightened with the sudden transition from the cage to the open room. The better plan would have been to have put the bird and cage in the room at night time with the door of the cage open. A fresh grass sod with a supply of food should have been placed near the front of the cage, so that when daylight began to dawn and the bird required its morning's meal, it would have gradually gained a knowledge of the open door for egress. Bechstein's "Chamber and Cage Birds," published by Routledge and Sons, price 3s. 6d., will afford you ample information as to general treatment, but not such treatment as your unfortunate frightened Lark sustained.—G. J. BARNESBY, Derby.

REMARKS.

17th.—Fair morning; heavy rain from 2.15 to 2.52 P.M.; wet evening.
18th.—Fine warm pleasant day.
19th.—Wet misty morning; fine from 11 A.M., very fine afternoon; damp night.
20th.—Wet close morning, dark for a few minutes, and heavy rain at 10.13, 0.06 fell in 7 minutes; finer in afternoon, misty evening and damp.
21st.—Dull morning, sunny afternoon, very fine evening rain at 10.45 P.M.
22nd.—Wet morning; fine after 10 A.M.
23rd.—Overcast at times, but fine day; very fine calm evening.
A fine mild spring week. The thunderstorm on the 17th passed much to the south of this station, and along its path was accompanied by a heavy fall of hail.—G. J. SYMONS.

COVENT GARDEN MARKET.—APRIL 24.

OUR market has been at such a standstill owing to the holidays that all classes of goods have experienced a serious decline, but being temporary we have made no alteration in quotations.

From observations taken near London during forty-three years, the average day temperature of the week is 64.0°; and its night temperature 39.2°.

HARDENING OFF.

BY this term is understood the gradual inuring of plants to a lower temperature so as to fit them to stand outside with little or no protection. For the propagation of half-hardy plants in winter or early spring by cuttings or seed it is generally necessary to employ artificial heat or a close atmosphere, and plants thus raised are for a time more delicate than those raised outside or in cold frames at a later and warmer period of the year. Even hardy plants when grown indoors become almost as tender as the ordinary occupants of the stove; and that this inability to stand cold is not got rid of as quickly as many people would seem to imagine, is, I think, proved by the fact that half-hardy plants which have been out all summer will bear with impunity a temperature many degrees lower in the autumn than they will in spring; in fact what will kill in the one case will scarcely leave a mark in the other.

I fear I am not able to teach much on this subject by anything I can write, but there is one particular agent in the hardening-off process which I wish to draw attention to, as I think it is not sufficiently taken into account. It may appear a little paradoxical to some when I say that the sun is one of the most important agents in preparing a growing plant to withstand frost. Once it will bear bright sunshine in the open air without flagging or discoloration a great deal has been done to fit it for a low temperature. We hear of plants being hardy in one place and tender in another, although the temperature in the latter place may not range so low as in the former. Very often the difference is caused solely by the difference in the amount of sunlight. Certain it is that plants grown under bright sunshine and in a dryish atmosphere are much hardier than those grown in comparative shade and a lower temperature. It will be in the recollection of a goodly number of your readers that less than twenty years ago we had two very severe winters, when the mercury was more than once down to zero. One of these severe winters followed a hot summer—I think it was the memorable one of Donati's comet; the other followed a summer as sunless as that of last year, with a still greater rainfall, and the difference in the effect of the two seasons was remarkable. In the former case the damage to hardy plants was comparatively small, but after the wet summer the frost played sad havoc with trees which had stood almost unscathed for forty or fifty years.

Many people, I think, get into a muddle in spring, and prevent all possibility of anything like method in their hardening-off arrangements, by mixing up hardy, half-hardy, tender, and very tender plants together. They say they have no room to do otherwise. Well, nobody has any room; there is no room at Chatsworth or Kew! But why do so many rear plants in February, March, or even earlier, which cannot be placed outside before midsummer, and would grow far better if not propagated till May?

It is true there are some few very tender plants—Dahlias, for instance—requiring to be grown on to a good size, and

therefore must be propagated early; but rearing such things as *Alternantheras*, *Coleuses*, *Heliotropes*, *Ricinus*, *Ageratums*, *Iresines*, *Zea*, or *Perilla* by thousands before May is a waste of time and labour, as well as a source of injury to most of the plants grown. We cannot of course in gardening matters do only one thing at a time or our practice would be a much more simple affair than it is at present, but it is well to go as far in this direction as we can with safety in all branches of our work by concentrating our energies on a few important things at a time, getting them off our hands, and consequently off our minds, to be followed in due course by other plants.

In the matter of propagating for the flower garden I practise and recommend beginning with such plants as will bear a few degrees of frost, as *Petunias*, *Verbenas*, *Alyssums*, *Mesembryanthemums*, and *Lobelias*. All of these will stand outside in a sheltered position in the southern part of England after the end of April, if they have been properly prepared for it. I will attempt to describe what I mean by being "properly prepared." It is not enough to merely move cuttings as soon as rooted into a lower temperature and then after a time to place them in a sheltered position outdoors. There are times and ways to do this. A cutting of a softwooded non-succulent plant should commence growing as soon as it is inserted, and if when it becomes a plant it is to make the best possible progress it should not be allowed to receive a check in any way. Unless, therefore, the hardening-off is done in a rational manner the plant is never more than half a plant. I will again take the *Verbena* as an example, it being at once one of the easiest of all plants to grow, and is perhaps the worst grown. We will suppose the stock plants are clean and vigorous, and are in a close pit or frame in which there is a little warmth from fermenting material, and the cuttings are in a fit condition to take off; there is even then a right and a wrong time to take them. Mr. Superficial says, "Wait till near the middle of the day when the sun is warm, and it will then do no harm to take the lights off." Well, if the frame has been kept quite close this is exactly the wrong time to do it, because the difference between the outer and inner atmosphere is so much greater now both in temperature and humidity than it was in the morning, that the plants will receive such a check as they will not out-grow all day. Either the cuttings should be taken early before the sun has raised the temperature, or air should be given early to prevent its rising too much till such time as the work at the frame has been finished, when it can be shut up, sprinkled with warm water from a syringe, and growth will at once commence again with increased vigour. Even opening a close dung-frame for a moment in the middle of a bright day will often inflict permanent injury on its occupants.

This hint about the time of taking off cuttings is the key to all the rest I have to say about hardening off. Never wait till the temperature of a house or frame has risen considerably before moving plants or cuttings. The time for all shifting of tender plants from a warm place to one with a little lower temperature is in the morning when not frosty, or during dull mild days at any time. In the morning

the hothouse may be 55° or 60°, and the outer air 35° to 40°—a difference of 15° to 20°. In the middle of the day the temperature of the house may have risen 30° or even 50°, while the outside air will not have risen in the same proportion, and consequently the risk of a check is much greater, especially if there is just a suspicion of nor-easter at the time. Finally, choose a time when what is known as a soft air prevails to place the plants outside. This condition of the air is almost independent of temperature, though not quite so much so of humidity or direction of the wind. I think a man should have just a touch of sciatica or "rheumatics" before he can quite master the subject of hardening-off or giving air.—WM. TAYLOR.

MARÉCHAL NIEL ROSE.

"I WISH I could say something more strongly in favour of this unique Rose, but the truth is it surpasses description: wherever a glass structure is erected for flower-growing Maréchal Niel should have a place in it." These are the words of your correspondent, "M. M.," on page 301, and with which I think every gardener in Great Britain will heartily concur. It is indeed a grand Rose, the grandest of Roses, and blooms with such freedom early in the season that it surpasses all others. I have found, like your correspondent, that it grows most rapidly under glass if left to its own will, and the only attention it requires with regard to pruning is merely thinning-out some of the weaker branches wherever they have become too crowded; but instead of planting it on its own roots I am favourably disposed to those plants worked on the common Briar stock. A Maréchal Niel budded on the Briar and planted outside any glass structure and the branches brought inside, much in the same way as Vines are introduced inside a vinery, will grow luxuriantly and yield a brilliant return of golden flowers. This, of course, prevents the extra work and sometimes inconvenience of preparing a border inside to grow it in. I planted a Maréchal Niel in the outside border at the back of a vinery last spring, and during March and April this year I was able to cut a large quantity of fine blooms, the only drawback being that the heat required for the Vines somewhat hastened the decay of the Roses.

The best place to grow this Rose is undoubtedly in a cool house, where it would receive just sufficient shelter from the inclemency of our spring months. In such a place it would have sufficient time to develop its massive and gorgeous yellow blooms. The examples of this Rose sent to the London spring shows by Mr. Walker of Thame, Oxfordshire, clearly tell us the magnificent standard this unique flower is able to reach.

I have yet another place to suggest to your readers for the protection and advancement of this Rose—namely, in conservatories. Many of these structures are so useless as to make the name almost a misnomer. They are often built either to harmonise with the architecture of the residence or made to utilise some ugly out-of-the-way corner, to please the fancy of the architect rather than for the protection and preservation of plants in bloom. In many of these lofty buildings Maréchal Niel will revel in all its glory if it can be only kept clear of green fly. I have now for several years grown a plant on the Briar in a lofty conservatory, and annually it has carried magnificent blooms; but there are drawbacks here in attaining success. From the close proximity of these buildings to the drawing or other dwelling rooms tobacco smoke cannot be employed to kill green fly, which is sure to put in appearance, and oftentimes a gardener is unable to syringe as heavily as he would like. This being the case, I have generally surmounted the difficulty and eradicated the enemy by the tolerably free use of tobacco powder and a heavy syringing now and then. The quantity of glorious blooms and the great service they render when cut flowers are in demand will amply repay any extra labour that may be required in these lofty places to grow this Rose to perfection.

We sometimes have the benefit of good flowers from a south or west wall; but the truth is, and it must be told, that the Maréchal is too precocious for our unsettled climate for us to depend on its outdoor cultivation alone. It is one of the very hardiest of Roses, but our mild and wet Januaries and Februaries start it in growth; then frost frequently occurs, and the tender shoots, unable to stand against it, become shrivelled up as if burnt with a fire. Plant Maréchal Niel in all available situations—north, south, east, or west—under glass, for wherever a glass structure is erected for flower-growing (I

again re-echo the words of "M. M.") "Maréchal Niel should have a place in it."—J. W. MOORMAN.

VEGETABLE CULTURE.

CHAP. XVI.—SPINACH AND SALSIFY.

SPINACH is seldom cultivated in cottage gardens. It is not supposed to contain much nutriment or possess much value as a vegetable, but this is not strictly true. Spinach is not only a useful vegetable, but it is exceedingly easy to cultivate, and it gives a large return for the space and attention it is necessary to give it. Still, it is not considered one of the principal kitchen-garden crops, yet a supply is always requisite in all large gardens and households. Unless for winter supply we never grow our Spinach on ground that could be cropped with anything else. When the early Peas are sown on the borders the rows are generally 6 feet or more apart, and Spinach is grown between them. It generally takes about six weeks to be ready for use from the time of sowing. The Peas are generally sown every ten or twelve days, and Spinach is always sown at the same time, and a succession is secured. The crop of Spinach is most satisfactory in a cool moderately rich soil. In hot shallow soils the plants seed quickly, and this is undesirable. We sow the seed very thinly, and do not thin the plants until they are fit for use, and at the first gathering the crowded plants are pulled out by the roots and used. This gives more room to those left to develop their leaves, and the larger these grow the better. As soon as the plants show signs of seeding they should be drawn out. From February until the beginning of July seed may be sown every fortnight or three weeks. When it is not sown between Peas it may be sown between any bush fruits, Raspberry rows, Rubus, or, in fact, anywhere, as it is more benefited than injured by shade in summer. It may be sown in narrow drills, but I prefer sowing it the width of a spade, as the plants do not become crowded so soon when sown in wide rows.

The winter Spinach crop requires some care to do it properly. Summer Spinach seldom dies prematurely, but winter Spinach often does, and that frequently when it is becoming fit for use. The leaves turn yellow and the plants die. We never had very much of it go off like this, but we have had a few rows affected, and it appears to be a small grub that eats the roots. Soot and lime forked into the soil before sowing the seed is a good preservative of the crop. While summer Spinach delights in a shaded place, the winter crop must have a fully exposed situation; an open south border is a good place for it. We generally sow ours on the part where the Early Horn Carrots were growing, and we find it succeed well after that crop; but it does well after Potatoes, Cauliflower, &c. The first sowing for winter should be made about the end of July, another the end of August, and the last at the end of September. In each case the ground should be dug over before sowing the seed, and a little manure added when the soil is poor. The seed should be sown in narrow drills 15 inches apart, and the hoe must be run between the rows frequently as soon as the rows can be seen and the soil is dry. We never thin the plants of our winter Spinach, and it always stands the weather well, but the large leaves are constantly gathered from it, and where this is not done the plants should be thinned out to 3 inches apart, as there is no doubt growing the plants packed together makes them tender and liable to decay. By sowing Spinach at all the times named a supply of it may be secured all the year round. We are trying some new sorts of Spinach this year, and we have tried some before, but for the main crops we still depend on the round variety for summer and the prickly sort for winter.

SALSIFY.

This is another vegetable not generally cultivated, but it is a valuable addition to our stock of vegetables, and where a great variety of dishes are wanted, as they are in most places, Salsify is quite indispensable in winter. It generally takes the place of a second-course dish at the table of the opulent, but with ordinary people it is cooked like Parsnips and used in the same way. The roots run into the ground like Carrots, consequently the soil should be free, open, and deep to grow them well. We generally grow our Salsify on the same quarter as the Beetroot, and all the ground is prepared alike. The seed should not be sown until the first or second week in May. When sown before this many of the plants seed in autumn. Fifteen inches apart is quite wide enough for the rows. The plants should be left 4 inches apart in the rows,

and the surface of the ground must be kept hoed and free from weeds. In October the roots should be taken up and stored amongst sand in a cool shed or cellar. Any indication of growth must be rubbed off, and decayed roots must be removed on their first appearance.

Scorzonera is another vegetable much resembling the Salsafy. Their culture and everything connected with them are so much alike that what applies to the one applies to the other.—A KITCHEN GARDENER.

SHOWING AURICULAS.

THE National Auricula Society is established and supported with the object of both improving and extending the cultivation of this charming Alpine flower. There can be no doubt whatever that the fine southern Show held in the Crystal Palace last year caused renewed interest being taken in the flower; and the still finer display of last week could not fail to give a still further stimulus to Auricula cultivation. Old growers and exhibitors are prompted by such displays to produce still better examples of cultivation, and new growers are encouraged to follow, but it must necessarily be "afar off" the present prizetakers and great exhibitors. It is with the object of reducing the distance that at present exists between old and new growers, or at least for preventing it becoming wider, as it must do under the present arrangements, that I venture to make a suggestion to the Committee of the National Society, which may or may not be worthy of official consideration.

It is self-evident that the great bulk of new Auricula growers must commence the culture of the flowers with not only small plants but a limited number of varieties, and these not of the most celebrated sorts. Of the dozen or two of plants of the beginner's it is not possible that all of them can be had in exhibition trim on a given day, and consequently unless some special provision is made to meet the case of such new growers they must wait for years before they can compete successfully. Most growers for obvious reasons commence with Alpines, or at least these are the most numerous in their little collections. Why not, then, have a mixed class of shows and Alpines of six or twelve plants, or both, for exhibitors who have not taken a prize say previously to 1877? In these "new exhibitor" classes let a winner of a first prize be prohibited from exhibiting in the same classes the following year, but leave the honour open for others. By this means direct encouragement would be given to new growers, and there would be a gradual and certain increase in the number of exhibitors. The plan of mixing the shows and Alpines is permitted on a large scale for large growers in the class for fifty plants, and surely, therefore, it would not be wrong to provide a smaller class of the same nature for smaller growers, and exclusively for new exhibitors.

It is well known that there is no possibility of amateur growers of Roses in pots competing with even a remote chance of success in the classes in which Messrs. Turner and Paul exhibit, and the chances of new Auricula exhibitors are equally hopeless when such great growers as Messrs. Horner, Douglas, Turner, and Simonite enter the lists against them. Give the novices a chance by providing classes of the nature suggested, and the number of growers and exhibitors will speedily increase, and so one of the chief objects of the National Society will be attained.

No doubt new and small growers have a chance of securing a fifth or sixth prize in the smaller classes now provided, and it is probable that they would endeavour to secure them if at the same time they had a reasonable hope of attaining a higher place in some other classes. If fifth and sixth prizes were offered for Roses in pots, stove and greenhouse plants, and Orchids, would a grower like Mr. Douglas compete for them if he knew he had no possible chance of securing a higher position? I trow not. In great plant exhibitions and shows of cut Roses a distinction is made between nurserymen and amateurs, but in the case of Auriculas this is not practicable; a distinction of the nature suggested is, however, not only practicable but is submitted as reasonable. It could not possibly injure the great growers, while it would directly encourage small amateur exhibitors. It is possible, too, that an increase of subscribers would be gained to the Society if special provision were made for new exhibitors, and it is not beyond the bounds of probability that some of the present subscribers would make a slight addition to their subscriptions for supporting a class or classes of the nature suggested.

Will the Committee of the National Society consider the matter? It might perhaps be deemed right to permit any growers who have not won a first prize since 1876 to compete in the extra classes, and such exhibitors the new growers would not hesitate to meet; but they are not likely to presume to meet the great guns who sweep all before them. It is pretty well understood that small amateurs' collections of Auriculas are being established, the very class that the Society is desirous of encouraging, and one way of doing so in a practical manner is by offering greater inducements for them to exhibit than at present exist.—EMBRYO.

PRUNING AND TRAINING PYRAMIDAL FRUIT TREES.

THE system of growing fruit trees in the conical or pyramidal form has for many years engaged the attention of gardeners and amateurs, and it is undoubtedly one of the most profitable modes in which to grow most kinds of hardy fruit. Many and conflicting are the modes of pruning recommended by various writers. One advocates close summer pinching, another practises severe pruning in the winter, and a third recommends shortening the shoots at midsummer, and evidence may be afforded that each plan is right.

In the formation of a fruit garden the first thing to be taken into consideration is site, which should be properly drained and trenched a year before the trees are planted. The next is to obtain good and well-trained trees from a nursery. If the trees have been transplanted several times they will have abundance of small roots, and every tree will be almost sure to grow. They should not be planted too deep, and should be securely staked to prevent them being blown about by the wind. The first year they should not be pruned but allowed to make all the growth they can. The shape of the tree should be the main thing to keep in view, and should any branches be inclined to grow in a wrong direction they can be brought right by tying them in the direction required while they are young, always keeping the lowest branches in advance of the upper ones. When the trees have made one year's growth they may be cut back considerably, keeping in view, as I said before, the shape of the tree. If the tree has made a strong growth it is not advisable to cut too hard, provided it has sufficient branches to form the framework of the future pyramid; if, on the contrary, it has made a short weakly growth it may be cut back closer and not be allowed to bear fruit too soon, otherwise it may become stunted. Presuming it has made a strong growth, the leading shoot should be shortened about a foot or 15 inches and the other branches in proportion. During summer if any shoots are formed that are not required to form the regular branches of the tree they should be removed, or shortened, as the case may be, but do not stop the main branches unless any are inclined to outgrow the others. Trees may be grown in this manner to the height of 12 to 15 feet.

In the pruning of pyramidal fruit trees of all sorts care should be taken to encourage the formation of natural fruit spurs in preference to artificial ones; this is the rock on which many a young gardener and amateur have split by following the orthodox system of summer pinching, as it is called. If a free growth is allowed during the summer and the branches kept thin, admitting a free circulation of sun and air among them, the wood will ripen properly, and at the base of every leaf a bud is formed which will ultimately become a natural fruit spur. In the case of some varieties, such as the Jargonelle and Williams' Bon Chrétien Pears, it will be found that the terminal bud of one year's growth will be a fruit or bloom bud; in such a case it will be advisable to pinch it out, which will strengthen the side buds, and in the following year they will become natural fruit spurs.

Among Apples and Pears certain sorts assume naturally very different forms of growth. Some grow close and compact, some horizontally and crooked, while others are slender and thin in their growth, and are indisposed to put forth lateral shoots—the Winter Nelis is of the latter class—in such a case it will be necessary to prune closer than in the others at the winter pruning. If the thinning of the shoots is attended to in the summer, and gross wood in the middle of the tree kept under, winter pruning will be reduced to a minimum. Trees brought into a bearing state by the above system of pruning and training will not require root-pruning so often as if pruned on the cut-and-back system, which unfortunately prevails among some in the present day. Root-pruning will become necessary in

some cases and in some soils more than others. When it is necessary to be done the trees should be lifted carefully with a ball of earth attached to their roots if possible, and the station of the tree well rammed, and the tree fresh planted with its base well above the surface. Care should be taken to keep it firm and the surface mulched with rough manure. In digging fruit gardens a spade should never be employed, and the ground should not be dug deeply. Top-dressings slightly forked-in help to keep the roots near the surface. It can easily be ascertained when a tree requires root-pruning by its making late growth and the wood not properly ripening, which is one great cause of canker.

Thinning the crops: It is common with most people to remark that the Apple and Pear bear well and the reverse in alternate years. The cause of this to a great extent is by allowing the trees to exhaust themselves by carrying more fruit in one season than they can well bring to maturity. Were the fruit judiciously thinned as soon as it is fairly set with something of a like care we bestow on our Peaches and Grapes under glass, our Apples and Pears and other hardy fruits would not only yield us year after year an ample supply of fruit, but that fruit would be of a very superior quality. Every deformed and undersized fruit should be removed with a pair of fine-pointed scissors. Some attention in this respect is bestowed on wall-fruit trees, such as Peaches and Apricots; in fact, if not thinned the crop in most cases would be worthless and the trees would be very short-lived. By early thinning the fruit another important end is gained—namely, the destruction of thousands of insects, the eggs of which are deposited in the embryo fruit.—W. GRAVES.

NORTHERN AMATEURS.—No. 2.

NOTES ON PICOTEEES AND CARNATIONS.

THE subject of these notes—Mr. Robert Scott, Oystershell Lane, Newcastle-on-Tyne—has devoted about forty years to the cultivation of the Picotee and Carnation, and as he has scarcely yet lived half a century an idea is afforded of how early he must have begun his career as a florist. This was, perhaps, owing to his father being an enthusiastic cultivator, and who was for forty years a stern representative of the intelligent northern florist. Being a cordwainer by trade, and possessing a sensitive nature and a refined taste, flower culture afforded Mr. Scott congenial relaxation from his confining duties. In his day, fifty or sixty years ago, the northern florists were very enthusiastic, and what we would term a "horticultural tournament" was in existence, and Mr. Isaac Scott did actually enter into an agreement with Mr. Hills as partner, against Mr. Henry Langley (cabinet maker) and Mr. Morris (pitman). The contest was to be decided by the number of prizes obtained at a series of shows, which would bring on the competition table almost all the florists' flowers then grown—Picotees, Carnations, Pinks, Polyanthus, Hyacinths, and Tulips. Tulip culture was then quite a mania. They were general favourites amongst our northern pitmen; some of them grow as many as five hundred, and some of these bulbs cost nearly or quite £3 each. This makes us almost wonder whether we still retain the same enthusiasm for flowers as did the preceding generation. Mr. Isaac Scott's Tulip garden was quite a furore amongst our northern cognoscenti. Every means was utilised and much cultural skill employed to bring the flowers to perfection. Tents were made for them large enough for the visitor to walk upright, and also globes were employed. Mr. Scott used to find his visitors so numerous that some means had to be adopted to limit them, and a price for admission did not prevent his numerous friends from coming for edification and friendly criticism.

For florist flowers the principal exhibitions were held in the Music Hall, Blackett Street, Newcastle, and here Mr. Isaac Scott won the silver and gold medal respectively for Pinks, Picotees, and Carnations. Amongst his favourite flowers in Picotees and Carnations were Mr. and Mrs. Campbell, Bailey's Beauty, Grace Darling, Rosette, Hutchinson's Lady Ridley, Butt's Lord Rodney, Martin's Splendid, and Harvey's Smuggler. These were a selection with which he generally succeeded in gaining honours. We have a little departed here from our immediate object in giving the history of Mr. Scott, sen., but if so it has been for a twofold idea. There is always a pleasure in recording the deeds of the valorous dead, and also to give some insight in the early training Mr. Robert Scott would receive under such a mentor.

Embracing the same trade as his father, attending on him

at all the local shows, and seeing every little secret in staging his flowers, besides naturally inheriting the keen perceptive qualities of a florist as well as studious and exhaustive patience, and confining himself nearly to the exclusive cultivation of the Picotee and Carnation, it would almost be superfluous on our part to say that as a grower of these flowers he would be hard to beat. His competition has been almost confined to the north, but his wish has been strong to "measure blades" with the southern exhibitors, but there is the unfortunate circumstance that their flowers do not bloom simultaneously.

The method of culture adopted by Mr. Scott is quite simple. He employs fresh turf, to which is added cow dung and horse manure thoroughly decomposed; he makes the beds in September, and plants during the same month the plants that were layered at the beginning of August or in July. Some he keeps in frames during the winter; these are planted in February. By this means he secures an earlier and later bloom. When the flowers are beginning to form pod he waters with clean water, and also shades with glass globes lined inside with white paper. For Pinks he uses a little stimulant in the shape of guano water. His success, he contends, lies in the attention that is bestowed upon them, visiting as far as twenty times a day, and attending to their wants as early as four in the morning. For such attention he has reaped a rich reward by never having had to succumb to any exhibitor. He has likewise been the means of bringing many local exhibitors out, which have reaped much benefit from his experience and advice. Of some of their floral exploits we hope to be able to say something hereafter. Appended is a selection of flowers of Picotees and Carnations which he considers the best for exhibition purposes.

CARNATIONS.—*Scarlet Bizarres*: Dreadnought, Admiral Curzon, and Sir Joseph Paxton. *Crimson Bizarres*: John Harland, Warrior, and Rifleman. *Pink and Purple Bizarres*: Sarah Payne, Lord Falconbridge, and Dodwell's Fanny. *Scarlet Flakes*: Clipper, Annihilator, and Superb. *Rose Flakes*: Flora's Garland, John Keet, and James Carter. *Purple Flakes*: Juno, Dr. Foster, and True Blue.

PICOTEEES.—*Rose Edges (Light)*: Miss Wood, Empress Eugénie, and Cynthia. *Heavy*: Edith Dombrain, Flower of the Day, and Miss Rodan. *Light Purple*: Mary, Amy Robsart, and Nymph. *Light Reds*: Thomas William, Mrs. Bower, and William Summers. *Heavy Reds*: Robert Scott (Flowdy), Mrs. Dodwell, and J. B. Bryant.

PINKS.—*Delicata*, Device, Bertram, Godfrey, Miss Nightingale, Ceres, and Criterion.—B. C.

PORTRAITS OF PLANTS AND FLOWERS.

DENDROSERIS MACROPHYLLA. *Nat. ord.*, Compositæ. This is a small tree about 13 feet high. Flowers bright orange.—"The genus *Dendroseris* is confined to Juan Fernandez group of islands, and the present species inhabits both the principal island and Masafuera, where it was discovered by Bertero in 1830, growing on the mountains, and flowering in May. The *D. macrophylla* was imported by Messrs. Veitch through their collector Mr. Downton, and it flowered at their nursery in August, 1877."—(*Bot. Mag.*, t. 6353.)

SPATHOGLOTTIS PETRI. *Nat. ord.*, Orchidaceæ.—"It is a native of the South Sea Islands, from where it was introduced by Mr. Peter Veitch. Though there are several Pacific Island species of the genus in the Herbarium none agrees with this in the very marked character of the deciduous bracts; these organs in the New Caledonian, Fijian, Malayan Archipelago, and Indian species being remarkably persistent, even long after the ripening of the fruit."—(*Ibid.*, t. 6354.)

ISCHARUM ANGUSTATUM. *Nat. ord.*, Aroideæ.—"This species," says Sir Joseph Hooker, "was found by myself in Syria in 1860, but I cannot tell exactly where, for the tubers were collected in September without flowers, and put in a bag with many other roots that I dug up as I journeyed along, and to whose generic name even I had then no clue. It flowered at the Royal Gardens first in December, 1861, and formed its leaves in the following January in a cool frame. I fail to identify it with any described species, and I find nothing like it in the Herbarium."—(*Ibid.*, t. 6355.)

FEVILLEA MOOREI. *Nat. ord.*, Cucurbitaceæ.—"Fevillea Moorei differs from the other species in its being quite glabrous, having entire three-nerved leaves, and very large flowers with short stamens; the leaves are obscurely biglandular at the base on the margin close to the petiole. The male flowers alone are known, which are very deciduous, the pedicel being

jointed in the middle. I have named it after my friend Dr. Moore, F.L.S., whose eminence as a scientific horticulturist is as well known as his garden is appreciated for botanical interest and beauty."—(*Ibid.*, t. 6356.)

ARDISIA OLIVERI. *Nat. ord.*, Myrsinæ. Native of Costa Rica. Flowers rose-coloured.—"By far the handsomest species of the genus hitherto cultivated in England, introduced by M. Endress into Messrs. Veitch's nursery, where it flowered for the first time in July, 1876."—(*Ibid.*, t. 6357.)

NATIONAL AURICULA SOCIETY.

CRYSTAL PALACE (SOUTHERN SHOW), APRIL 25TH.

THANKS to the energy of Mr. Dodwell and the zeal of both northern and southern growers another great field day of the Auricula has been held, an opportunity afforded of meeting the lovers of this beautiful flower from all parts of the compass, and a delightful time for comparing notes, shaking by the hand of many a fellow lover of the flower; and as one of its oldest admirers I have to tender to Mr. Dodwell and the liberal patrons of horticulture by whom he was supported my humble thanks, all the more disinterested as I was not able to enter into the fray as I have been wont to do. As, however, I hope my collection is in a fair way of recovering from the attacks of its bitter enemy the woolly aphid I hope another year may see me again as a competitor.

In recording my opinion of the Exhibition I cannot say that I think in the quality of the flowers exhibited there was the same high standard attained as last year. I in vain looked round for such a George Lightbody as Mr. Horner exhibited last year, or such a Lancashire Hero as Ben Simonite's; while in a large number there was a roughness that indicated either a strong use of stimulants or a condition of climate that was prejudicial to their opening, while there was not much absolutely new or valuable in the seedlings exhibited. One, indeed, shown by Mr. Douglas (Silvia) was a first-rate flower. It had defects as nearly every Auricula has—the paste was too scolloped and the body colour too small, but it was a flower of great refinement, and will, I have no doubt, be found a valuable variety. Indeed I see no reason why, if science and care be brought to bear on the hybridising of the Auricula, we should not have new varieties to take the place of many we are obliged to put up with for want of better.

Amongst the green edges Booth's Freedom, a flower rarely seen, was exhibited in good condition by Mr. Horner, but was not so smooth as I have seen it. Talisman, a seedling of Ben Simonite's, bears considerable likeness to it, and as it is apparently a good grower will be a valuable addition. Prince of Greens, which I never consider a superior flower, was not shown in such good condition as last year. It has a tube, which is fatal to any flower, and especially to a green edge, and its habit is frequently elegant. It has indeed a grand edge, and that is its great point, but I shall not break the tenth commandment as far as it is concerned. One of the very best of green edges, Imperator, I do not recollect to have seen, but Leigh's Colonel Taylor in one or two instances was very fine. Page's Champion was good, Alderman Wisbey coarse.

In grey edges George Lightbody still holds its own as the very best not only in its class but the best Auricula in growth, and Mr. Horner's plant of it carried off the prize as the premier flower shown, but, as I have said, it was not shown as well as last year. Alderman Brown was well exhibited; indeed in one class where it and George Lightbody were shown together they were as nearly alike as possible. Lancashire Hero still holds its place, and they are a worthy trio. Alexander Meiklejohn is doubtless a very fine variety, but it will not, I think, displace either Lancashire Hero or George Lightbody. An old flower, Sir Henry Havelock, was well exhibited by Mr. Turner, and although somewhat cupped was as shown a very refined and good flower.

Whites as usual were weak. Mr. Simonite's new flower, Frank Simonite, is an acquisition; but it is somewhat curious that, despite all that has been said, Summerscales' Catharina, an old flower, was placed first in the class-showing. Smiling Beauty is no doubt a lovely flower, but the colour of the edge is not so white as in Catharina or Taylor's Glory, which latter, however, is so early as never to be of much use for exhibitors. Traill's Beauty, though classed as a white, is too grey. Walker's John Simonite, exhibited by Mr. Horner, was quite one of the best in this section.

In selfs the palm must be given for smoothness and depth of colour to Pizarro, which was well shown, as was also a dark seedling of Ben Simonite's. Charles James Perry was also finely exhibited. Ellen Lancaster was also good; while some of the other selfs, such as Blackbird, Mrs. Smith, and Lord Clyde, were in fair condition.—D., Deal.

AFTER the above critique by the veteran florist, which is not far off the mark, we have little to record beyond submitting the names of the prizewinners and the varieties composing their collections. Indeed the arrangements of the Show were such as to

preclude an examination of the flowers in a manner that in the interests of the public is desirable. One of the printed conditions of the Show states explicitly that "the plants must be ready for the Judges by 10 A.M.;" but the staging of the plants was not completed until upwards of an hour after that time, and before the Judges had completed their duties the public rush occurred. Notetaking in the thick of a Crystal Palace crowd results in a series of hieroglyphical characters that are simply undecipherable. A glance at the Show, however, was sufficient to perceive that it was a display of great magnitude, the Auriculas occupying six tables, each about 20 feet in length, one table being devoted to Polyanthuses and two others to miscellaneous exhibits. Taking our estimate from the table that was filled with three collections in the class for fifty plants, it may be inferred that about 900 Auriculas were staged and 150 Polyanthuses.

It is not easy to fix a day to suit growers situated both in the cold north and sunny south. Had the day been a week earlier Mr. Ben Simonite could not have competed, and had it been a week later Mr. Douglas's best flowers would have been over. These facts afford the best evidence that the date of the Show was fortunate, because fair to all.

As yet the number of exhibitors of Auriculas increases slowly. Last year the prizetakers were Messrs. Horner, Douglas, Turner, Simonite, Cooper, Margetts, and Jones—seven; this year they were Messrs. Horner, Douglas, Turner, Barlow, Simonite, Dean, Llewelyn, and Margetts—eight. Mr. Curtis also exhibited this year. It is interesting to observe that the relative positions of the chief exhibitors are nearly the same this year as last. The champion, the Rev. F. D. Horner, remains far ahead of all rivals. He won, if we are right in our enumeration, twenty-five prizes last year, and the same number last Thursday. It is singular also that Mr. Douglas secured exactly the same number of prizes at both the Shows—fourteen. Mr. Turner had twelve prizes last year and ten this, Mr. Simonite four last year and five this. A new exhibitor at the Palace, Mr. Barlow, won an excellent position by securing seven prizes, and Mr. Llewelyn, also a new exhibitor, won four. Mr. Margetts had one prize last year and two this, and Mr. Dean had this year two prizes awarded. Mr. Jones, who was a prizewinner last year, did not compete this year, and the late lamented Mr. Cooper of Timperley secured three prizes in 1877. The Auriculas were in the aggregate finer—i.e., larger, this year than last, but not more refined: that applies to the edged flowers. The selfs were not so good as last year, but the Alpines were better. There was a great advance in both numbers and quality in laced Polyanthuses, yet there is plenty of room for still further advancement.

The Judges—the Rev. F. Tymons, Clogran, Drumcondra; S. M. Tandy, Esq., Clorinda Park, Kingstown, Co. Dublin; and Messrs. T. Moore, T. Baines, and A. Parsons, awarded the prizes as follows.

In Class A, twelve dissimilar varieties, the Rev. F. D. Horner, Kirkby Malzeard, Ripon, was in the premier place; Mr. Douglas, gardener to the President of the Society, F. Whitbourn, Esq., Loxford Hall, Ilford, second; Mr. B. Simonite, Rough Bank, Sheffield, third; and Mr. Charles Turner, Slough, fourth. Mr. Horner's collection comprised Walker's John Simonite, Lee's Col. Taylor, Booth's Freedom, Lancashire's Lancashire Hero, Traill's Prince of Greens, Simonite's Frank Simonite, Heap's Smiling Beauty, Campbell's Marquis of Lorne, Headly's George Lightbody, Smith's Ann Smith, Page's Champion, and Horner's Sapphire, a very fine purplish plum-coloured self. Mr. Douglas staged generally larger plants of Turner's Charles J. Perry, Col. Champneys, and Master Hole, Campbell's Admiral Napier, Kay's Alexander Meiklejohn, Beeston's Apollo, Hepworth's True Briton, Lightbody's Lord Clyde, Smiling Beauty, and George Lightbody, and a distinct and chaste silvery grey-edged seedling, which was certificated and afterwards named Silvia. Mr. Simonite's flowers, which were not quite fully expanded, were Reed's Ruby, Waterhouse's Conqueror of Europe, Campbell's Duke of Argyll, Sykes' Complete, Lancashire Hero, Traill's Beauty, Marquis of Lorne, Samuel Barlow, Frank Simonite; John Simonite, a fine seedling self with foliage as white as that of Centaurea candidissima, and rich velvety almost black flowers resembling Master Hole; and a seedling green-edged flower after the manner of Col. Taylor. Mr. Turner staged C. J. Perry, Robert Traill, Col. Champneys, Horsefield's Highland Queen, Sims' Eliza, Cunningham's John Waterston, Lancashire Hero, Turner's Sarah, Martin's Mrs. Sturrock, and Headly's Arabella.

In the class for six dissimilar varieties five collections were staged. The Rev. F. D. Horner headed the list with Prince of Greens, George Lightbody, Smiling Beauty, Booth's Freedom, and Lancashire Hero. Mr. Simonite was second with Frank Simonite, Talisman, Marquis of Lorne, Lovely Ann, and the two seedling selfs. Mr. Douglas third with Col. Champneys, Alexander Meiklejohn, Lord Clyde, Alderman Wisbey, Charles J. Perry, and True Briton. Mr. Turner was fourth with Omega (a new white-edged flower), Alderman C. E. Brown, Charles J. Perry, Col. Champneys, Mrs. Sturrock, and John Waterston. S. Barlow, Esq., Stakehill House, Chadderton, Manchester, was fifth with Litton's Imperator, Col. Taylor, Pizarro, Marquis of Lorne, Ne Plus Ultra and Mrs. Smith.

In the class for four varieties, dissimilar, six collections were staged. Mr. Horner was placed first with Pohlman's Ellen Lancaster, Smiling Beauty, Freedom, and Lancashire Hero; Mr. Douglas second with Campbell's Lord Palmerston, Charles J. Perry, Smiling Beauty, and Alexander Meiklejohn; Rev. B. H. Margetts, Liffington, Uppingham, third with Imperator, Alderman C. E. Brown, Summerscales' Catharina, and Mrs. Smith; Mr. Simonite fourth with Frank Simonite, Ann Smith, Samuel Barlow, and a seedling; Mr. Barlow was fifth with Traill's Beauty, Lovely Ann, Marie, and Marquis of Lorne; and Mr. Turner was sixth with C. J. Perry, Col. Champneys, True Briton, and Lee's Bright Venus.

The Rev. F. D. Horner was again in the foremost place in the class for two varieties with Lancashire Hero and George Lightbody. Mr. Barlow and Mr. B. Simonite were second and third respectively with the same varieties; Rev. B. H. Margetts fourth with Lovely Ann, very fine; and J. T. D. Llewelyn, Esq., was fifth with two seedlings, one a neat grey-edged flower, the other a bold flower with very dark body colour on a white paste.

Single Specimens.—*Green-edged.*—Fifteen plants were staged. Rev. F. D. Horner was first and sixth with Col. Taylor and seventh with Freedom, Mr. Simonite second with Hudson's Apollo, Mr. Douglas fifth with Beeston's Apollo and eighth with Lord Palmerston. *Grey-edged* (eighteen plants).—Rev. F. D. Horner was first with Alderman C. E. Brown and second and third with George Lightbody and Lancashire Hero respectively, Mr. Douglas was fourth with Alex. Meiklejohn, Mr. Horner fifth with Complete and sixth with George Lightbody, Mr. Turner was seventh and Mr. Horner eighth with the same fine variety. *White-edged* (twenty-five plants).—Rev. F. D. Horner was first with Summerscales' Catharina, second with John Simonite, third with Smiling Beauty, sixth with Ann Smith, and seventh with McDonald's Miss Arkley; Mr. Douglas was fourth and fifth with Catharina and eighth with Miss Arkley. *Selfs.*—Rev. F. D. Horner had the first three prizes with Pizarro, Meteor Flag, and Reed's Ruby, and the fifth and sixth prizes with Meteor Flag; Mr. Douglas was fourth with Sims' Eliza, and Mr. Barlow seventh with Meteor Flag. This was not a superior class.

The class for fifty plants in not less than twenty varieties was an imposing one. Alpines were included in this class, and five collections were staged. Mr. Douglas secured the first prize with splendid examples of culture—indeed, plants more vigorous have perhaps never been exhibited than these, but they were not so fresh as Mr. Turner's admirable second-prize collection. Mr. Douglas's plants consisted of Hudson's Apollo, very good; Lancashire Hero, Lancashire Hero, Sims' Vulcan, Chapman's Maria, Sykes' Complete, Smith's Lycurgus, Turner's Master Hole, Oliver's Lovely Ann, Spalding's Metropolitan, a grand truss; Headley's Alderman Wisbey, Traill's Beauty, very good; Kay's Topsy, Lady Sophia Dumaresque, Lightbody's Robert Traill, Campbell's Marquis of Lorne, Campbell's Admiral Napier, Lightbody's Lord Clyde, Turner's Colonel Champneys, Hepworth's True Briton, Traill's General Niel, Pohlman's Ellen Lancaster, Gain's Lady Richardson, Cunningham's John Waterston, Smith's Britannia, Perry's Charles Turner, Campbell's Confidence, Cunningham's Mrs. Campbell, and Lightbody's Meteor Flag. The more noticeable of Mr. Turner's varieties were Turner's Charles Perry, Turner's Minstrel, Finlayson's Sir R. Peel, Ives' Bishop of Lichfield, a fine dark self; Lightbody's Richard Headly, Turner's Clipper, Jeffrey's Sir H. Havelock, and Turner's Calypso, a good purple self—in fact self predominated in this collection. Fine as this collection undoubtedly was, the plants being remarkably clean and fresh both in foliage and flowers, it was overpowered by the extreme luxuriance of the Loxford plants. J. T. D. Llewelyn, Esq., Yniaygerwn, Neath, had the third prize with a very creditable collection. Mr. Dean, Ealing, and Mr. T. Curtis, Atherton Grange, Wimbeldon, also competed. The plants of the last-named exhibitor were border Alpines, some of the trusses being of great size.

ALPINES.—In the class for twelve plants four collections were staged. Mr. C. Turner secured first honours with King of the Belgians, a grand dark flower; Slough Rival, an equally fine light variety; Mrs. Thomson, a rich dark flower and splendid truss; Queen Victoria, a beautiful light-centred variety; Dolly Varden, Unique, Beatrice, very fine; Napoleon III., Mrs. Dodwell, John Bull, and Miss Froud—all, we believe, raised at Slough. Mr. Douglas was a good second with Turner's Bronze Queen, very fine; Prince, Florence, and Queen, raised at Loxford; Gorton's Diadem, Beatrice, Neatness, Miss Reid, Minnie, Selina, Spangle, and a seedling. Mr. Barlow was placed third and Mr. Llewelyn fourth in this class with good collections.

In the class for six plants the prizes were awarded to Messrs. Turner, Douglas, Barlow, Dean, and Llewelyn in the order of their names. Troubadour in Mr. Turner's collection was remarkably fine, as also was Sensation, while Silvia attracted notice in Mr. Douglas's collection. The remaining varieties were the same as those mentioned in the preceding class.

Twenty-eight plants were staged in the class for a single specimen Alpine. Mr. Turner secured the first prize with Miss Taplin, a large smooth flower with a creamy centre; the petals are maroon slightly shaded with violet. The same exhibitor was second with

Mariner, a striking maroon slightly shaded flower with pale yellow centre. Mr. Dean was third with Captivation, a truly captivating laced flower that was certificated last year. Mr. Douglas was fourth with Meiklejohn's Mrs. Meiklejohn, a richly shaded flower of great merit; and Mr. Turner was fifth and sixth with King of the Belgians and Unique.

Premier Auricula. The flower selected from the entire Exhibition which won this great honour was George Lightbody, exhibited by Rev. F. D. Horner. Although the truss was symmetrical and composed of nine pipes it was not quite equal to the premier flower of last year.

In the Polyanthus classes Mr. R. Dean, Ealing, was first for six gold-laced varieties with Exile, Lancer, Formosa, George IV., Earl of Lincoln, and President; S. Barlow, Esq., was second with Cheshire Favourite, Exile, George IV., President, Lancer, and a seedling; Mr. John Beswick, Middleton, third; and Mr. James Douglas fourth, in whose collection the same varieties were represented. For two dissimilar varieties Mr. J. Beswick was first with Cheshire Favourite and Exile; Mr. S. Barlow second with Cheshire Favourite and President; Mr. W. Brownhill, Sale, third with Cheshire Favourite and Exile; and Mr. R. Dean fourth with Cheshire Favourite and Cox's Regent. In the class for a single specimen Mr. Brownhill was first, second, and fifth; Mr. S. Barlow third and fourth; Mr. Beswick sixth; all showing Cheshire Favourite.

CERTIFICATES.—These were awarded to

Silvia (Douglas).—A silvery grey-edged flower, the result of a cross between George Lightbody and Robert Traill. Paste very pure and circular; body colour faint; segments rather pointed. A distinct and attractive variety.

Omega (Turner).—White edge. Pure white circular paste; body colour black, good eye; edge a little irregular or crimped. A striking, but as exhibited not a refined flower.

Annie (Barlow).—Self. Purple maroon, shaded pale purple, small round creamy centre; petals stout, and flower well formed. Excellent.

Queen (Turner).—Alpine. Colour maroon, slightly shaded violet, centre pale yellow; fine truss. A smooth and striking flower.

Mariner (Turner).—Alpine. A fine flower previously described.

Mrs. Meiklejohn (Meiklejohn).—Alpine. Exhibited by Mr. Douglas and alluded to above. The best new dark-shaded variety exhibited.

National (Turner).—Alpine. Bold, clear, creamy centre; petals broad and well formed; colour maroon, faintly shaded with purple. Smooth and fine.

Certificates were also awarded to Mr. Dean for Polyanthuses Royal Sovereign and Lustrous, the former a yellow self with round flowers and fine truss, and the latter a glowing crimson flower with golden centre and fine Auricula-like truss; very fine. A certificate was also awarded to Mr. Ware for Golden Eagle, which closely resembles Royal Sovereign, and a similar award was granted to Mr. Hooper, Bath, for fancy Pansy F. Perkins, a large striking flower; colour velvety purple maroon shaded with pale purple.

Amongst the miscellaneous exhibits we noticed a trio of Alpine Primula Auriculas exhibited by Mr. Llewelyn—namely, P. A. Marginata, brought by L. L. Dillwyn, Esq., M.P., from the Gemmi Pass, Switzerland; it had mealy foliage, bright yellow medium-sized flowers, and good truss; very pretty. Another plant from Grindenvold, Switzerland, had long narrow foliage and a tall truss of Cowslip-like flowers; the remaining plant being very similar to it. Mr. Hooper, Bath, contributed a brilliant display of Pansies; Mr. Ware a collection of herbaceous and Alpine plants; and Mr. Dean an attractive group of Primula amœna vars. Mr. Turner, Slough, arranged an extensive and beautiful assortment of Azaleas, Roses, Pelargoniums, and Auriculas. These plants, interspersed with Palms and fine-foliaged plants excellently grown by Mr. Thomson at the Crystal Palace, formed a valuable adjunct to a beautiful Show.

MANCHESTER (NORTHERN SHOW), APRIL 30TH.

I HAVE just had the pleasure of seeing a very beautiful display of Auriculas at the Manchester Town Hall, and, reserving my observations thereon until next week, merely append the list of prizes. It will be noticed that Mr. Horner's name does not appear, he not having exhibited, the ordeal his plants went through in their southern visit having been enough for them.

Class A, six Auriculas.—1, Mr. B. Simonite; 2, Mr. H. Wilson, Halifax; 3, Miss Stewart, York; 4, Mr. E. Pohlman, Halifax; 5, Mr. C. Roysds.

Class B, four Auriculas.—1, Mr. Simonite; 2, Mr. H. Wilson; 3, Mr. Woodhead; 4, Mr. C. Roysds.

Class C, two Auriculas.—1, Mr. R. Gorton; 2, Miss Stewart; 3, Mr. B. Simonite; 4, Mr. T. Mellor.

Class D.—Premier, 1, 3, 4, and 8, Mr. Wilson; 2, Mr. W. Taylor; 5 and 6, Mr. Simonite; 7, Mr. Roysds.

Class E, single grey edge.—Premier and second, Mr. Woodhead; 1, 3, and 7, Mr. Booth; 4, Mr. Taylor; 5, Mr. Wilson; 6 and 8, Mr. Simonite.

Class F, single white edge.—Premier, Mr. Taylor (Smiling Beauty); 1, Mr. Wilson; 2, Mr. Partington; 3 and 4, Mr. Simonite; 5, Mr. Booth; 6 and 8, Miss Stewart; 7, Mr. Mellor.
 Class G, self.—Premier, 1, and 6, Mr. Roys; 2, Mr. Bateman; 3, 4, 5, and 8, Mr. Wilson; 7, Mr. Pohlman.
 Best green edge in the Exhibition.—Mr. H. Wilson.
 Best grey edge in the Exhibition.—Mr. Woodhead.
 Best Lancashire Hero.—Miss Stewart.
 Best four Alpines.—1, Mr. Booth; 2, Miss Stewart; 3, Mr. Gorton; 4, Mr. Barlow.
 Best yellow ground.—1, 2, 3, and 4, Mr. Booth; 5, Mr. Bateman.
 Best white ground.—1, 3, and 5, Mr. Booth; 2 and 4, Miss Stewart.
 —D., Deal.

THE PRESTON SHOW OF THE ROYAL HORTICULTURAL SOCIETY.

It was with unfeigned gratification that I heard of the intention of the Council of the Royal Horticultural Society to resume their provincial shows, which in former years were productive of so much benefit both to the Society itself and to horticulture, by the organisation of such a show at Preston for next July. Such manifest signs of vigour and true horticultural interest encourage us to look for great things in the future from the Society. But I cannot keep silence when I read the anonymous communications which appear in the columns of your contemporaries, written by correspondents who evidently know nothing whatever of the arrangements made, and of the spirit which pervades both the Council of the Society and the Local Committee at Preston, from the Mayor of the town, who is Chairman, through every member of the Committee. I happen to be acquainted with some of the members of the Council, who are quite in earnest, I can assure you, in spite of the assertions of the anonymous writers to whom I allude; and from the reports of friends at Preston I feel equally certain that the energetic Local Secretary, Mr. Shuttleworth, has all the ability as well as all the determination to ensure a grand success in spite of what is being said to the contrary. Such statements must come from people who want to see a failure, and as an ardent horticulturist I hope you will be able to put such information from time to time before your readers as will supply the true facts of the case.—FAIR PLAY.

OUR BORDER FLOWERS—GRASS OF PARNASSUS.

It may appear at first sight somewhat out of place to say that such moisture-loving plants as Parnassias should be placed among border flowers. Whatever may be said of the origin of these plants, there need be no hesitation in saying that they are among the choicest of our border flowers. They are said to have had their origin on Mount Parnassus, a famous mountain of Greece, hence the name Grass of Parnassus, but have no resemblance to any Grass that I am acquainted with. Why it is called Grass at all I am unable to say. In the autumn many places of our country, especially marshy districts and Alpine regions, wet hills and moist moors, are covered with this beautiful plant with its charming white flowers. When seen in quantities in its native home it leaves an impression that is not easily effaced from the mind of the beholder. The plants are seldom met with in cultivation, but they can with care be turned to good account. They are very effective on moist shady rockeries, yet they will bear full exposure to the sun when supplied with water. They are charming plants for margins of ornamental waters, and they will well repay any amount of labour bestowed upon them in cultivation. They are not particular as to soil; moisture is their chief element. They are increased by seed sown as soon as ripe in any place where the plants can have light and moisture, and by division in the spring. Four or five species are enumerated which reach us from the North American Continent, but our own *Parnassia palustris* is the choicest of them all, and ought to be taken in hand by all cultivators of our border flowers.—VERITAS.

NOTES AND GLEANINGS.

WE are glad to know that a movement which promises to be very successful is in progress for holding a PEOPLE'S FLOWER SHOW at South Kensington on Whit-Monday, June 10th. Already several handsome subscriptions have been received towards the expenses, and some of the leading exhibitors—among whom are Messrs. Veitch, Williams, Osborne, Wills, and others—have undertaken to contribute of their floral wealth towards the display, which is expected to be an imposing one.

The Lord Mayor has very kindly promised to countenance this endeavour of the Society to add to the enjoyments of the great masses of the working population of the metropolis, and we believe that some of the City companies will also identify themselves with the movement.

THE ROYAL NATIONAL TULIP SOCIETY'S SHOW is announced to be held at the Manchester Botanical Gardens on June 1st. The Society, which is under the patronage of the Queen, has for its President and Hon. Secretary an ardent florist, Samuel Barlow, Esq., Stakehill House, Chadderton, near Manchester. Prizes to the amount of £60 are provided, and energetic efforts are being made to render the Show a success and to strengthen the Society, which is established for promoting the cultivation of the Tulip. The schedule is composed of thirteen classes—nine for rectified Tulips and four for breeders. Seventy prizes are offered, commencing with £5 or a cup for five stands of twelve dissimilar Tulips, with proportionately smaller amounts in the smaller classes.

AT the Show in connection with the MAIDSTONE ROSE CLUB to be held on July 3rd, a silver challenge cup value £12 is provided for the best box of eighteen blooms. The cup is to be retained by the winner for the year, and will become the property of the member who shall win it at three exhibitions, not necessarily consecutively. A challenge cup of the value of £8 is also provided for a device consisting of Roses combined with Ferns or other foliage. Only members of the Club can compete at the Show. Rev. Alan Cheales provides prizes for the best Hybrid Perpetual and the best Tea and Noisette Rose in the Exhibition. We are glad to observe from the cash account of 1877 that the income of the year exceeded the expenditure by £2 13s. 4d. Mr. Hubert Bensted is the Secretary.

ROYAL HORTICULTURAL SOCIETY OF IRELAND'S FIRST SPRING SHOW for the present year, held at the Exhibition Palace, Dublin, was, says the *Irish Farmers' Gazette*, of a high order of merit in every department, and in several classes was very much above the average. The cups for exotic plants and Azaleas were won by Mr. Westby. Mr. Boyle, Mr. George Orr Wilson, Mr. Bracken, Mrs. Mander, and Miss Power also exhibited well in the plant classes. In the florists' section there was a capital show. The Lord-Lieutenant's cup for eighteen Hyacinths was won by the Solicitor-General with a first-class collection. There was a large display of Auriculas, the principal exhibitors being Mr. Leland, Mr. Chaloner, and Rev. Frederick Tymons. Roses were largely shown, the first prize being awarded to Mr. Riall for a splendid box of *Maréchal Niel*. Excellent stands of Pansies were exhibited by Mr. Leland, Mr. Comyns, and Mr. Riall, and two capital stands were exhibited, not for competition, by Mr. W. Paul, nurseryman, Paisley. Some good dishes of dessert Pears were shown by Mr. T. P. Hogg and Capt. Isacke, a good dish of dessert Apples by Mr. Millner, and well-kept baking Apples by the last-named exhibitor and Mr. Hogg. Vegetables were first-rate, especially those exhibited by Mrs. Manders, Mr. Wilson, Mr. Comyns, and Mr. Reid.

AT Fern Lodge, Ascot, Mr. Southard's charming suburban residence, a visitor informs us the POLYANTHUSES are magnificent. Armfuls of flowers, he says, are produced by some of the roots, and the rich effect produced by the glowing masses of these hardy spring flowers is splendid. The soil is sandy loam. Conifers are also in remarkable vigour. The gardens and other adjuncts of the residence, such as poultry conveniences and the miniature home farm, are all in that high state of keeping which renders a visit to them peculiarly enjoyable.

MESSRS. ALEXANDER SHANKS & SON, of Dens Iron-works, Arbroath, have designed and constructed a TROPICAL GARDEN which is shortly to be erected at Gothenburg. The garden will consist of five houses substantially built of iron and glass, each one heated to the temperature of the countries from which its exotic occupants have been drawn. The structure, which weighs nearly 200 tons, will be roofed with nearly 40,000 feet of glass.

THE extent of ground devoted to the cultivation of SEAKALE in the London market gardens indicates how great is the demand for crowns for forcing purposes. Not only are scores of acres especially prepared and planted for producing crowns of the first quality, but during the past spring gangs of men and women have been engaged in planting "sets" of Kale between the rows of Cabbages. The Cabbages are cut early, and the Seakale then covers the ground and forms

moderate-sized crowns by the autumn. The sets are planted in drills with dibbers. Three or four men draw the drills, two or three women lay out the sets, and a gang of twenty men follow and insert them, the "ganger" walking backwards and forwards before the plants to see that the work is done properly. This close supervision is the more necessary since nearly all work in the market grounds is done by the "piece." This plan of growing Seakale and forcing the crowns in batches is much cleaner and more economical than the old mode of having the stools 3 feet apart and covering them with piles of manure.

— A CORRESPONDENT writes:—"Visitors to HAMPTON COURT GARDENS will bear with extreme regret and indignation that during the winter those fine and ancient avenues of Limes have been for all time completely disfigured and their beauty destroyed. The lower branches, which so gracefully swept the turf, being the admiration of all and adding so much to the beauty and enjoyment of these unique grounds, have been cut away. The trees now are primed some 12 feet high, destroying the shade and seclusion, and opening out an almost uninterrupted view of the grounds, exposing only bare trunks—in fact, destroying the picturesqueness and grace both of the trees and the gardens. It seems a pity that such vandalism should be permitted, and that the beauty and charm of these ancient and time-honoured monarchs of the forest should be despoiled."

— THE GENIAL WEATHER that has lately prevailed has caused the foliage of deciduous trees to unfold with great rapidity. Many Chestnut trees in the vicinity of London have nearly completed their season's growth and the flowers are just expanding. It is noteworthy that the Horse Chestnut makes all its growth in less than a month, and this year that growth has been hitherto unchecked. Last year the frosts of spring despoiled the Chestnut trees of their beauty, and they had a rusted appearance throughout the season. Lilacs, early Thorns, and Laburnums are just showing the colours of their flowers, and *Wistaria sinensis* is flowering freely on south walls in the neighbourhood of the metropolis. We never saw the foliage of hardy trees expand more freely and appear more healthy than at the present time.

— ALTHOUGH AURICULAS are hardy plants and usually expand freely in cold frames in the southern counties, yet the plants will not only endure artificial heat, but in the case of flowers grown in the north such assistance is imperative to have the plants "in" for the southern shews. Mr. B. Simonite informed us at the Crystal Palace that every flower he had there had expanded during the week previous to the Show in a temperature of 60° to 70° solely by fire heat. Not only had there been no sun at Sheffield, but a dense chilly fog had prevailed, and the atmosphere was as thick and murky as it usually is in November. In order to keep the flowers clean tiffany is fixed across the ventilators to filter the soot-laden air. Such are the obstacles the stern cutler florist has to contend with; he surmounts them, and emphatically deserves the honours he wins.

— IN "Familiar Wild Flowers" there are the following notes on the GLASTONBURY THORN. "Near Glastonbury Abbey stands an old Hawthorn that has been the subject of many legends, the current belief, however, being that it sprang from the staff of Joseph of Arimathea, who, it is asserted, was the first preacher of Christianity to Britain, and who, to convince the benighted islanders of his mission, thrust his staff into the ground, where it at once budded and blossomed. The tree has ever since flowered, not only at its proper season, but also at each Christmas, the anniversary of its miraculous origin. A piece that came under our notice on December 16th had eight bunches or corymbs of flowers on it. Each of these was composed of from twenty to thirty blossoms and buds, about a dozen of the flowers in each corymb being fully expanded. The blossoms were a little smaller than would ordinarily be looked for, but had all the beauty and regularity of form and the characteristic Hawthorn scent of the normal plant. The only thing abnormal in the appearance of the spray was the absence of the foliage. The Glastonbury Thorn is not absolutely unique; some few others, as at Romney and near Nantwich, possess the same peculiarity of flowering twice, first in May and again about the end of the year."

— We learn that Mr. BATTERS, who has for upwards of nine years been gardener at Chilworth Manor, Romsey, is about to resign his charge there. Mr. Batters is known as a

successful gardener, and has often exhibited excellent vegetables grown in pots at the meetings of the Royal Horticultural Society.

— AT the Great International Exhibition held at Philadelphia in 1876, there were exhibited some extraordinarily large sections of various species of trees from California and Oregon, amongst which, besides the *SEQUOIA GIGANTEA*, or *WELLINGTONIA*, with the dimensions of which we are already familiar, there were several notable examples of gigantic growth. Two sections of the Oregon Yellow Pine (*Abies grandis*) were exhibited, which were cut from a tree 321 feet in height, and 15 feet 9 inches in diameter at the butt. The first section was taken at the height of 130 feet from the ground, and measured 6 feet 10½ inches in diameter, exclusive of the bark. The second section, taken at 200 feet up, measured 5 feet 10 inches in diameter of solid timber. A fine section from the same State of *Abies Menziesii*, taken at the height of 98 feet from the ground, was 6 feet 10 inches in diameter, and the tree from which it had been cut was stated to have been 318 feet in height, and 16 feet in diameter at the butt. A magnificent section was also exhibited of the Oregon Red Cedar (*Thuja gigantea*), which measured 22 feet in diameter, and was taken from the base of a tree said to have reached the gigantic height of 325 feet.

HINTS ON LANDSCAPE GARDENING.—No. 4.

VILLA GARDENS.

ON page 245 it was stated that there are large Elms in the garden at The Firs, Lee. These are the English variety, *Ulmus campestris*; and it was by no means intended to imply that this Elm should be planted in other small gardens, for notwithstanding the rapidity of its growth, its gigantic proportions and stately appearance when full grown, and the long period of its existence in favourable sheltered positions, the wood is so brittle that in exposed situations there is much risk of damage from high winds. Many a noble tree have I seen wrecked by storms—limb after limb broken off, till it became such an unsightly spectacle that it had to be cut down.

Trees deciduous and evergreen, ornamental and durable, are, however, plentiful enough. Which shall we choose? Here are a few taken from a regular host of well-trying favourites, and first of all comes *Robinia Pseud-Acacia*, Cobbett's much-praised Locust Tree, attaining a height of about 40 feet, worthy of a prominent position for its elegant foliage and pretty white flowers; and the Rose *Acacia*, *Robinia hispida*, of about half the height of the *Pseud-Acacia*, with charming racemes of pink flowers. The Tulip Tree of more lofty growth is equally ornamental in its way, and may well be termed a large handsome-flowering tree, suitable either for mixed groups or for isolated specimens. It is a tree much affected by soil and situation. In sheltered positions and deep rich loam I have more than once met with it 80 feet high, but it will more frequently be found not to exceed half that height; yet though dwarfed by exposure and poverty of soil it is always handsome in growth, foliage, and flower. The Horse Chestnut, though much more common than the Tulip Tree, is equally beautiful. It answers well in most soils, but is worthy of the best soil we can give it, for nothing can be finer than its masses of handsome foliage, and the beauty of its bold spikes of white pink-blotched blossom is too well known and admitted to need one word of praise from me. This tree gains much in effect when associated with the common white-stemmed Birch—the one so massive and stately, the other so graceful and sprightly. By all means plant the Birch; always ornamental. It increases in beauty with age, and has peculiar charms at different periods of the year. In spring the fresh lively greenery of its opening buds is singularly pleasing; in summer the long pendent growths yield to the breeze, swaying to and fro in wild yet graceful disorder; and in autumn and winter not only do the white stems and red branches impart brightness and tone to their surroundings, but the branches—when the spray is laden with thousands of little globules of water, as is always the case on dull foggy days—afford us one of the most beautiful sights in Nature. Another tree which tells well near the Horse Chestnut is the Fern-leaved Beech, *Fagus asplenifolia*, of somewhat slender growth, and well clothed with handsome foliage.

I have already called attention to the value of the Snowy Mespilus for small gardens, and must not omit the stately *Ailantus glandulosa*, a somewhat dwarf tree, growing about

20 feet high, but which its fine foliage renders wonderfully effective. Then, too, there is our old favourite Judas Tree, of about the same height, with a somewhat spreading top, heart-shaped foliage, and flowers of a purplish hue; the red Maple (*Acer rubrum*), the dark purple Maple (*Acer polymorphum atropurpureum*), both said to attain a maximum height of 20 feet, but I have seen *rubrum* nearly 30 feet. *Pavia rubicunda*—better known, perhaps, as the scarlet-flowered Horse Chestnut

—makes a pretty dwarf tree of about 10 feet; and I must not omit the Mountain Ash (*Pyrus Aucuparia*), with its sweet-scented flowers and bright red berries. It answers very well in a poor thin soil, and is said to grow 40 feet high in a rich soil. The finest I have seen would not exceed 30 feet, and I should be glad to know where finer specimens are to be seen. The Stag's-horn Sumach (*Rhus typhina*) and the Guelder Rose (*Viburnum Opulus*) are both worthy of a place, as are many

Fig. 50.—DESIGN FOR A VILLA GARDEN.

- X. Seat at end of terrace
- The marks x x x indicate position of large trees.

more which I must not enumerate, and yet the Lime must be included, for it is, perhaps, the most useful of all, forming a thick, dense, yet spreading growth, making a capital screen when in leaf, and when in flower most delicious with sweet perfume.

Leaving evergreen trees and shrubs for my next communication, attention must now be given to the arrangements in the design for a villa garden (fig. 50). It is drawn to a scale of 32 feet to an inch. The villa and pleasure grounds would there-

fore require a space measuring 166 feet by 160, and the design might very easily be adapted to a garden of double the size, an enlargement of the area to be dealt with of course affording facilities for the introduction of other features. The broad walk in front of the house may be raised if the house stands upon a higher level than the lawn, in which case a flight of steps opposite the centre of the house should lead down to the lawn. Circular beds might be introduced for the Roses, but

the single large bed (H) would be better for the Roses, in affording more space for the roots and greater facility in the application of manure. The specimen trees upon the central lawn need not necessarily be Conifers, but very large trees in the centre of so small a garden are objectionable. The shrubs in the beds (Q Q) may be continued to the points (I I) if it is desirable to shut-in the front lawn from the carriage drive; the wall by the perennial border (I) to be turned to account for Tea Roses or other climbers. If space could not be afforded for the pyramidal fruit trees as shown in the kitchen garden, espaliers, or rather trees trained in the improved French method termed *Palmette Verriers*, could be used instead.

The kitchen garden is suggested to be formed at the right of the plan, and to which walks (T T), are represented as leading.
—EDWARD LUCKHURST.

THE CRYSTAL PALACE AURICULA SHOW.

To what is to be attributed the very bad arrangement of the Auricula Show at the Crystal Palace? The good nature of the Secretary, the dilatoriness of exhibitors, or the remissness of the Crystal Palace authorities? Wondering at seeing a crowd of people surrounding the flowers while the prize labels were not added, and inquiring what it meant, I was told that the judges were not admitted until an hour and a half after the time specified, that subscribers and their friends were admitted while the judging was going on, and that long before they had finished the public in general were obliged to be let in. This ought not to be. The judging of florists' flowers requires great quiet and no disturbance from outsiders. Rules should be made and be adhered to, or competent judges will refuse to act. I write this as a well-wisher and not in any spirit of opposition.—VISITOR.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE present is a very busy time for all persons connected with a garden. Gardens that a fortnight since were both neat and clean have now become overrun with weeds unless the hoe and spade have been in constant use; and the grass plots that were short and neat have grown quite long, and must have immediate attention to maintain them in good order throughout the season. Under glass the same rapid movement has occurred. Vines are growing apace, and bedding and other plants that a short time since had plenty of space are now become crowded, and will consequently, unless removed, soon become drawn and weakly. It is surprising what an impetus a few days of brilliant sunshine, when accompanied with genial showers, give to vegetation at this period of the year.

Vines.—In houses where little or no artificial heat can be given the Vines have now started well into growth, and must have timely attention if a good crop of ripe Grapes is wished for. The young shoots must be tied down to the wires which are run across the house to support them. The strongest shoots on each spur should be retained and the smaller growths be rubbed off. As the shoot increases in length it is brought down gently to the position it is to retain. This work requires much care to prevent the shoot from snapping off. It should be remembered that by the breaking-off of a young shoot at this season the loss of a bunch of Grapes may be a small evil in comparison with denuding the Vine of a permanent spur where one is required for producing fruit in future years. Secure the shoots, therefore, to the wires with care and judgment. A few shoots may be brought to their positions at once, but others require the exercise of much patience, and must be brought down an inch at a time over several consecutive days. Many Vines are permanently injured by the young shoots being roughly handled, and by being secured to the wires in a hurried manner. Pinch off all bunches of fruit except one on each lateral, and stop each shoot two leaves beyond the bunch. In the course of a short time laterals will grow from these young shoots, which must be further stopped at the first leaf or joint. Syringe daily until the Vines are in bloom, which can easily be detected by the perfume they emit. Vines in full bloom are very sweet, the perfume resembling that given off by *Mignonette*. If the structure in which the Grapes are growing can by any means be artificially heated apply heat by night while the Vines are in bloom; it will facilitate the process of setting as well as lengthening the bunches. In all cases damp the floors and stages, and close the house early to conserve the solar heat. Grapes that are already set should have the berries thinned with a pair of Grape scissors, removing the smaller berries and thinning sufficiently for those left to swell and grow to a large size.

Bedding plants continue to place out of doors under mats, or temporary protection to harden-off. This will allow of more space within for the more tender plants to advance in size. Increase *Fuchsias* by cuttings if required, and pot off those already struck. Shift into larger pots any that have become

root-bound and which are wanted to attain specimen size, using light friable soil. Give plenty of moisture at the root and overhead, and maintain a close, shaded, and humid atmosphere, and the plants will grow very rapidly. Stop the shoots by taking out the points up to within eight weeks of the time the specimens are wanted to bloom; they will then flower very regularly, and when fully out their drooping graceful flowers render the plants very valuable for decorative purposes.

Herbaceous *Calceolarias* in their blooming pots are becoming root-bound, and should be assisted with liquid manure while throwing up their trusses of flowers. Whenever green fly appears fumigate the plants with tobacco paper before the fly cripples the blooms.

Chrysanthemums must not be allowed to stand about in small pots until their roots have become matted together, but should be shifted into larger pots as the plants require. Place small sticks to the shoots, and place the plants on a bed of coal ashes to prevent worms from entering the pots. We strongly recommend early-struck, and by this time well-established plants, both for growing into specimens or for producing blooms of high quality. Stop the shoots of plants that are intended to grow bushy, but for large flowers we let the majority of our plants grow naturally. Plants of medium height can be had by merely stopping once and only allowing two, or at the very most three, breaks to grow up. We have found plants so treated produce blooms very little inferior to plants not stopped, and amateurs with limited glass houses have not as much difficulty in housing such plants in the autumn as when the plants are left to grow without being stopped. Do not by any means allow them to suffer by want of water, or the bottom foliage will turn yellow and subsequently fall off. Slow steady growth and well-matured wood produce the largest and best flowers.

Auriculas are just now in their full beauty, and are verily amateurs' flowers. Converts to this old-fashioned but popular florist flower would do well to pay a visit to a good collection, note the freest-growing and showiest varieties, and order a collection accordingly, or, failing this, make a selection of varieties from those named both in last and this week's Journal.

Many shrubs in the borders of our pleasure grounds are now in full bloom, particularly the double-flowering Cherry, *Berberis Darwini*, various *Rhododendrons*, the double-flowering Gorse (its golden-covered heads are now most gorgeous), *Pyrus japonica*, and *Mahonia aquifolia*, while the flower beds are bright and gay with *Myosotis*, Wallflowers, *Polyanthus*, Pansies of various shades, more especially the blue and yellow selfs, and double Daisies. These, if kept free from weeds, will for the next few weeks greatly enhance the beauty of the grounds. Insert cuttings or slips of double Wallflowers under handglasses; those taken off with a slight heel of old wood strike best. Sow seed at once of the single variety, and subsequently transplant the seedlings for next spring's supply.

Asparagus will now soon be plentiful. Cut the heads level with the soil; by doing so you avoid injury to advancing growths which are yet under the soil. Keep the beds clear of weeds. Stir the ground around Cauliflowers, and give liquid manure twice a week to the plants. Run the hoe through advancing crops of Onions, Parsnips, and Strawberries, and myriads of seedling weeds will be destroyed, and the crops will be otherwise benefited. Draw soil to and stake Peas before they fall over and require propping up. Early Potatoes are coming fast through the ground; draw as much soil as possible around them to prevent injury from further late frosts. Jerusalem Artichokes may yet be planted if not already done, planting the sets fully 2 feet apart every way. For growing in odd corners or blocking-out unsightly objects we know of nothing to equal the Jerusalem Artichoke; it is also a profitable and palatable vegetable.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sow at once the main crop of Dwarf Kidney Beans in rows 2 feet 6 inches apart, and place the Beans about 4 inches distance in the rows to allow for casualties, afterwards thinning the plants to a foot distance apart. Canadian Wonder and Negro Long-podded are the best; Ducrot is a recent introduction of great merit. Scarlet Runners should be sown at once; the drills, if the Beans are to have stakes placed to them, 6 feet apart, placing the seeds 6 inches apart. Some dispense with stakes, stopping the plants instead, in which way they produce well. The rows for this mode of culture must not be less than 3 feet apart. We prefer staking, having at our command larch stakes of about 8 feet in length. We grow a row of Dwarf Beans between the rows of Runners, the rows being north and south. Trenched well-manured ground is essential, with plenty of moisture after the plants come into flower, along with mulchings of short manure. Champion (Carters') is very superior to the old Scarlet Runner, and Suttons' New Giant is an excellent and very prolific variety with long pods. Mont d'Or Butter Beans should be sown now in rows 6 to 6 feet apart. They require stakes 6 feet in height, or may be grown the same as Scarlet Runners. In cold localities they require a warm

situation. The pods are cooked whole and are very delicious. Premier Runners are very prolific. They require stakes of 4 to 5 feet. All the small-seeded Beans should be covered with soil 2 inches deep, Scarlet Runners rather more, the seed requiring to be covered rather deeper in light soil than in heavy.

Broccoli should now be sown for the main late crop, also Savoy, particularly the dwarf varieties, which come in early in autumn and take up little room. They afford nice heads if the plants are grown 1 foot apart; the varieties Tom Thumb, Early Vienna, King Koffee, and Early Elm being improvements in quality upon the larger varieties. Make good the plantations of Cauliflowers; any that are "blind" or have buttoned pull up and replace by plants from the early spring sowings in heat. Plants will now be ready from the earliest sowings to plant out, and to maintain a supply of close heads plant out a sufficiency for the demand every fortnight or three weeks. Coarse heads are a result of distant plantings. We plant in rows 2 feet apart and 18 inches asunder; greater distance is no advantage, the heads having to be cut whilst small, so with more space great waste would be incurred. If large heads are wanted the distance may be 8 feet every way.

The thinning of spring-sown crops of roots will soon require attention, an operation often too long delayed, whereas they should be thinned when the plants can well be handled. We thin in the first instance to about half the distance it is ultimately intended the plants should be from each other. Carrots are thinned to 8 inches distance for the Horn kinds, 4½ to 6 inches for the long varieties, which admits of every other plant being drawn in a young state without any detriment to the main crop, the second thinning being very serviceable. Parsnips are thinned the same distance as the long varieties of Carrots, as we have a demand for the roots in a small state, but where there is no demand for them thin-out the full distance—viz., 9 to 12 inches. Salsify and Scorzonera are thinned to from 6 to 9 inches asunder, Chicory the same, Beet being left 9 to 12 inches. Onions are taken in hand so soon as they can be handled, partly for saladings, but we thin them to 2 inches early, which leaves plenty for spring Onions, finally thinning them to 6 inches. If the thinnings are planted-out closely they will form small bulbs for pickling. Seed of Silver-skinned or Two-bladed Onion sow now thickly in beds of poor soil for producing small Onions for pickling purposes. The autumn-sown Onions are now growing rapidly; they will have been thinned and probably stand about 8 inches apart. Water them if necessary between the rows, and as they form bulbs every other plant may be drawn for use, they being very serviceable at this time when the old Onions are becoming soft. No Onions seem to find greater favour with cooks than the white—Neapolitan Marzago, White Tripoli, White Lisbon, and especially the Queen. If large specimens are wanted the most promising plants must have every opportunity of acquiring full development, allowing 9 to 12 inches distance from plant to plant. Fly the hoe frequently between the rows of growing crops, which is promotive of growth as well as destructive of weeds.

HARDY FRUIT GARDEN.

Notwithstanding the severe frosts late in March we have a fair show of Apricots, which are swelling rapidly, the trees having abundance of foliage, so that where evergreen branches have been employed as protection they should be removed a few at a time, so as to inure the foliage gradually to full light and air. Canvas or other screens being employed must be used whenever the nights are frosty, removing them in the morning early and letting them down late at night, being guided in those respects by the weather. The foliage will probably soon be infested with the green caterpillar (*Ditula angustiorana*), which folds itself up in the leaves. It should be sought for—picked off or crushed by the finger and thumb. Peaches and Nectarines have set well, and, like the Apricots, are very forward in foliage, which is quite as tender as the blossom and young fruit; therefore the protecting material must be employed at night whenever there is an appearance of frost. Aphides will probably soon infest the Peach, Nectarine, Plum, and Cherry trees. Tobacco juice diluted with six times the quantity of water, strained, and the trees syringed therewith is an effectual remedy, applying it during a mild calm evening. If mildew appear upon the Peach and Nectarine trees dust thoroughly with flowers of sulphur. Keep a keen eye upon the Gooseberry bushes for caterpillars, and destroy them at once with hellebore powder applied with a dredger. Keep down weeds by using the hoe frequently, tap-rooted weeds being forked out. Strawberry plantations should be mulched with half-decayed litter. It is beneficial in keeping the soil moist by lessening evaporation, and being well washed by rains forms by the time the fruit is ripe a good surface for the fruit to rest upon. A mulch of some kind is quite necessary, as the rains drive the soil more or less upon fruit that is staked or which rests on wire (estacoline) supports; but we allude to this subject now to point out the necessity of a mulch in order to secure as much moisture as possible in the soil when drought comes.

FLOWER GARDEN.

Cannas if not yet started should be at once placed in heat. A nearly spent hotbed covered with a few inches of decaying leaves

answers well for plunging the roots in, they doing better in this way than when potted. *Caladium esculentum* and other fleshy-rooted plants employed for bedding may be treated in the same way. *Erythrina*s are fine when planted-out in warm situations. They should now be started in gentle heat, and prepared for planting-out in June. When the young shoots are a few inches long take them off with a heel if increase be wanted; if placed in a hotbed they soon strike. Subtropical plants raised from seed as before advised should be potted and grown-on in gentle heat, so as to have them strong for turning out early in next month. There is plenty of time for raising plants of *Amaranthus*, *Chilian Beet*, *Ricinus*, *Zea*, and other of the quick-growing subtropical plants, those raised from seed sown now being usually superior to those from earlier-sown seed. *Dahlia* roots may be planted-out in the open ground, planting them about 4 inches deep, and an inverted flower pot will give all the protection required.

Lawns require frequent attention in sweeping, rolling, and mowing in order to secure a close bottom. Daisies disfigure a lawn; perseverance in grubbing them up is the most certain means of riddance. Other coarse weeds should be removed in a similar manner. If their removal cause any bareness dress and fill-up the holes with a little fine soil, pressing it down with the back of a wooden rake, sowing seeds of the Suckling Clover and the finer Grasses, such as *Cynosurus cristatus*, *Festuca tenuifolia*, *F. duriuscula*, *Poa nemoralis sempervirens*, and rolling them in well. The grass verges should be well rolled and then be cut with the edging knife after rain, when the turf will be soft and the operation easily and neatly done. The verges after being cut will have a much better appearance than before, and much after-labour with the edging shears will be saved.

Gravel walks quickly become weedy at this time of year. By keeping the weeds well under now much trouble will be saved at a later period. Walks too full of weeds for hand-weeding may be hoed about an inch deep and have the surface raked during dry weather until the weeds are destroyed. This will brighten the surface wonderfully, rains washing the surface clean, which can afterwards be made smooth with the roller.

FRUIT HOUSES.

Vines.—Muscats when in flower set most freely with a night temperature of 75° to 70°, and 85° to 90° by day with a free circulation of air. Liberate the pollen by gently tapping the bunches or shaking the Vines at mid-day. Encourage late kinds of Grapes by damping frequently and syringing freely morning and afternoon. Keep the evaporation troughs well filled with liquid manure, employing it for damping the floors, &c. Admit air early and moderately, employing no more fire heat than is absolutely necessary, closing early in the afternoons of bright days so as to husband the sun heat, which is very much more beneficial than fire heat. Thinning must be proceeded with as soon as the berries can well be distinguished. Those that take the lead in swelling and having stout footstalks are likely to swell well and stone. Thinning at this time of year should be done on dull days or in the cool of the morning or evening. It is much more comfortable for the operator, and contact with berries, when the hands of the thinner are heated, is not likely to favour good finish. Superfluous bunches must be removed with no sparing hand. See that the borders have sufficient water, and that crops swelling the fruit have a good supply of atmospheric moisture, and those colouring have plenty of warmth by day with moderate ventilation, not omitting to leave the upper lights a little way open at night. Fire heat will only be necessary in the earliest house after the crop is fully ripe in cloudy weather to admit of free ventilation.

Peaches and Nectarines.—The fruit in the earliest house is fast approaching ripening; when it begins to ripen the supply of water should be gradually lessened and the syringing discontinued. If the foliage overhangs the fruit the removal of some of the leaves is imperative, the shoots being well tied-in so that the fruit may have all the sun and light possible. The fruit when nearly ripe should be kept from falling on the ground by netting stretched beneath the trees to catch such as drop. Disbud and thin the fruit in the succession houses, but do not be in too great a hurry about the later. Let the first thinning be done when the fruit is the size of a horse bean, leaving about twice the quantity it is intended the trees should bring to maturity, and wait before further reducing the number of the fruit until they swell prior to stoning. If they pass this stage well remove all superfluous fruit, for we have never found any to drop of any consequence after this stage is passed. Leave the quantity of fruit required—those best placed on the shoots—for the sun and air to have access to them. Keep the shoots well tied-in. Attend well to the watering of inside borders, not superficially, but make sure the roots are reached by it, syringing morning and evening. Keep the late houses cool by free ventilation, so that the succession of fruit may meet that of the earliest in the orchard house or on walls.

Melons.—Success in Melon cultivation depends upon a firm soil of a rather strong adhesive character but not devoid of grit. When the soil is light, loose, and rich the shoots are long-jointed, the leaves thin and flabby, not enduring sun; the fruit then does not set well, and those that do are light in weight for their size

and very indifferent in flavour. It is necessary that the shoots be thinly trained to prevent overcrowding. Keep the atmosphere dry and well ventilated when setting, being careful not to allow one fruit to take the lead upon a plant, watering well when the fruit is swelling, and keeping dry when ripening. Do not spare the knife after the fruit has commenced swelling freely, keeping the principal leaves fully exposed to light and air. Attend to setting the blossom in bright weather, nipping-out the points of the shoots one joint beyond the fruit. The earthing of plants in frames must be attended to, the fruit when swelling being placed upon a slate or inverted flower pot, sprinkling the plants at closing time through a fine rose, but avoid wetting the neck or collar, which should be kept free of leaves or canker will ensue. It may be kept in check by rubbing until dry with quicklime, and prevented by placing quicklime around the stem. Attend well to linings, maintaining a good internal warmth, watering with tepid water as required once or twice a week. Sow for succession.

Cucumbers.—In the hottest part of the day the plants will require slight shade from bright sun, but shade them as little as possible; in houses with the lights facing east and west shading will not be necessary. Syringe in the afternoon from 3.30 to 4 o'clock, well damping the floors several times a day in bright weather. Apply liquid manure to the roots about twice a week. Thinning the shoots, stopping, training, and top-dressing must be attended to as required. In pits and frames timely attention will be required in stopping the shoots one joint beyond the fruit, removing any superfluous shoots and bad leaves as they appear, earthing as the plants advance. Attend to the linings, watering with tepid water, sprinkling overhead at closing time—about 8 to 8.30, and continue the night coverings, especially when cold. Pot-off the ridge kinds, and grow-on preparatory to planting out.

Orchard House.—The prospects of the fruit crops are cheering. Apricots are well set and should be slightly thinned, but not until the fruit is fairly swelling. Strong or superfluous shoots should be pinched or rubbed off, and all shoots likely to interfere with the symmetry of the trees should be pinched. The green caterpillar not unfrequently preys upon the young shoots and leaves; it may easily be detected by the leaves being drawn together. They should be unfolded, the caterpillar removed or destroyed by gently pinching the leaves infested. Abundant supplies of water will be required. Weak liquid manure may be given twice a week. This applies more particularly to trees carrying a heavy crop of fruit. Aphis is very troublesome upon Peaches and Nectarines, the fruit of which set well. Syringing must be resorted to every morning about seven o'clock when the day promises to be fine; but this, though it checks the insects, is not always effectual in eradicating them, and fumigation may be necessary. It should be done upon a calm evening and in moderation, with the foliage of the trees perfectly dry. Quassia chips 4 ozs. to a gallon of water boiled a quarter of an hour, strained, adding whilst cooling 2 ozs. of soft soap, make an useful solution in which any shoots infested with green or brown aphis may be dipped; where dipping is not practicable apply the moisture to the infested parts with a soft brush. If mildew appear dust with flowers of sulphur. Black fly on Cherry trees yields to repeated fumigations or diluted tobacco juice. Cherries to set well require abundance of air. If the fruit set very freely as it usually does upon trees under glass, especially trees in pots, thin it with scissors. Ventilation must be carefully attended to. In mild bright weather the ventilators will need to be opened from seven to eight o'clock in the morning, but in cold weather they should remain closed or only slightly opened. Close early so as to shut in the solar heat; no danger need be feared from a rather higher temperature during the latter part of the afternoon. Water will be required liberally by the various trees now they are in growth, none requiring it more freely than Figs, which if once allowed to become too dry will cast the young fruit.

PLANT HOUSES.

Stove.—Amaryllises which have ceased flowering and requiring more pot room should be potted forthwith and before the young growths are considerably advanced, or they receive a check which is not favourable to a vigorous growth. They like rather strong loam, good drainage, and the roots disturbed as little as possible. Pot firmly, and instead of mixing manure with the soil feed the plants with liquid manure. *Gesnera zebrina splendens* and *G. exoniensis*, *Eucodonia*, &c., which have been dried-off, should now be potted, placing six or more strong corns in a well-drained 8-inch pot, covering about an inch deep, and employing a compost of turfy loam with a fourth of leaf soil and a sixth of sand. Water sparingly until growth takes place, then more freely as it advances. *Ardias* should have a light airy position when they are in flower. Their berries do not set freely in a close moist atmosphere. Seeds may now be sown in gentle heat, potting-off the plants when large enough to be handled and growing them on. It is necessary that the plants during their entire growing period have sufficient light to keep them sturdy, upon which depends their value for decorative purposes. Shift *Gloxinias* into larger pots, potting-off seedlings, which if grown-on during the summer will bloom finely in autumn. Afford liquid manure to plants showing for bloom in small pots; this is often preferable to

increasing the size of the pots. *Achimenes* when commencing flowering are benefited by the application of liquid manure not too strong. *Poinsettias* which were cut-back as advised will have grown so as to afford cuttings of 4 to 6 inches in length. These, if taken off with a good heel and inserted singly in small pots in sandy loam with a little peat, strike freely in moist brisk heat and shaded. Old plants answer fairly if they are shook out when the shoots are 2 or 3 inches long and the plants placed in heat until fresh roots are formed, then keep rather cool so as to secure sturdy growth. Turfy loam with about a sixth of sand will grow them well.

Ferns are generally grown in too much heat and have too little air, which causes their fronds to endure only a short time in a cut state, and upon the plants they also sooner become sere. Air should be admitted rather freely and the atmosphere kept cool and moist. Stove Ferns in a majority of instances do not require a higher temperature by artificial means than 60° to 55° at night from this time up to October, and a rise of 10° to 15° by day. Sprinkling overhead must be practised morning and evening, or in dull weather damping every available surface twice a day will be sufficient. Aphides and thrips are kept under by fumigation, which must, however, be moderate and the foliage of the fronds dry. A majority of *Adiantums* have the young fronds injured by fumigation, notably *A. farleyense*, which it is best to remove to another house when the house is smoked. Liberal supplies of water will be necessary now that the plants are in free growth.

Nepenthes when commencing growth require slight shade, but they must be kept near the glass, having abundance of water at the roots, and be syringed in the morning and early afternoon, maintaining a moist atmosphere by frequent sprinklings of all available surfaces. Potting should now be done, avoiding over-potting. Provide very efficient drainage, as should the soil become sour the plants never prosper. A compost of equal parts of chopped sphagnum and very fibrous brown peat with the small particles sifted out, a fourth of crocks, and a sixth of charcoal broken up rather small, with the barest sprinkling of sand, form a suitable compost.

Orchids.—The temperature should now be increased. East Indian house, 70° to 90° by day, 70° to 65° by night; *Cattleya* house, 65° to 75° by day, 65° to 60° by night; *Odontoglossum* house, 60° to 70° by day, and 60° to 55° by night. In the East India house *Aërides*, *Phalænopsis*, and *Saccolabium* should be kept constantly moist and the foliage clean by frequent sponging with clear water. *Odontoglossum* and cool *Orchids* generally do best in a lean-to house facing the north. Some few require a little more heat than others, as *O. citreum*, *O. hastilabium*, and *O. novium*. *Lycastes* with the *Odontoglossums* named should be grown at the warmest end of the house. *Masdevallias* do best in the coolest part grown by themselves. Repot after flowering. They should not be placed in too large pots, especially plants with unhealthy roots, which should be carefully cleansed by washing with tepid water. *Cymbidium* repot. Good drainage is necessary. Rough peat with small lumps of charcoal is a suitable potting material. Free watering is necessary. *Stanhopeas* after flowering should have the moss renewed about them, and the baskets frequently dipped in tepid water. Sponge the leaves of all *Orchids* frequently to keep them free of scale or other pests, which if not promptly met soon disfigure the foliage. Fumigation is the best remedy for thrips, but it must be done moderately.

TRADE CATALOGUES RECEIVED.

Francis & Arthur Dickson & Sons, Upton Nurseries, Chester.—*Catalogue of Bedding Plants, New Roses, &c.*
George Cooling, Bath.—*Catalogue of Roses in Pots, and Lists of Herbaceous and Bedding Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

LOCAL HORTICULTURAL SOCIETIES' RULES (W. B. A.).—If you refer to our No. 538 you will there find them fully detailed under the heading "Village Horticultural Societies." They fill between two and three pages.

LONDON SHOWS (*Juvénile*).—The first summer show of the Royal Botanic Society will be held at Regent's Park on May 22nd; and the great summer show of the Royal Horticultural Society will be held on May 28th, 29th, 30th, and 31st at South Kensington.

ROSE OF SHARON (*E. S.*).—We cannot identify the plant from the small specimen of seed you sent. Send a portion of the plant itself when in bloom. We do not know any plant which is called the Rose of Sharon.

TRA-SCENTED ROSES NOT EXPANDING (*Quatin*).—They would probably

have expanded had they been kept in the vinery; the lower temperature of the greenhouse has caused a check to the plants. There is no remedy but more warmth; or the atmosphere of the greenhouse may be too moist, the plants being syringed overhead, whereas they should be kept dry, but should have plenty of water given at the roots. Continue the plants in the greenhouse, affording them a light airy situation.

FRAXINELLAS (P. H. G.).—Prick the seedlings out 2 inches apart in pots or boxes, and place them in a light cool frame, in order to produce sturdy and healthy plants for planting-out in June. You have been fortunate in raising a stock of plants so quickly. The seedlings will thrive in a compost of loam, peat, and leaf soil. Keep them close and shaded from bright sun for a few days until they commence rooting in the fresh soil, after which let them have light and air gradually until they will endure full exposure.

INDUCING CROTONS TO FLOWER (E. Martin).—You will more quickly induce flowering by growing on the plants in a light airy situation until they are a good size than by cramping a small plant in a small pot. It is essential that the plants be large, and then by confining the roots and being sparing of water when the growth is complete, the growth being made in full light so as to thoroughly ripen the wood, the plants will flower. The most luxuriant Crotons that we have seen were grown by Mr. Legg at Cleveland House, Clapham Park. The plants, which had been grown rapidly in a high temperature and a light house, flowered profusely when they were two years of age, and they had no check whatever. We think *C. volutus* was one of the plants that flowered, and was at the time probably the finest and most luxuriant plant in England.

VINE SHOOTS DECAYED (D. C.).—The roots of the Vines must be in sour or stagnant soil, which has caused them to decay, or they must have sustained injury by some other cause. If your border requires draining drain it at once, and if fresh soil is necessary remove the old soil down to the roots and apply turfy loam or the best garden soil at your command, and mulch it with manure. Healthy surface roots are what you must encourage, and you must also ventilate carefully. It is possible that you do not admit air sufficiently early in the morning. Give air earlier and gradually; do not syringe the Vines nor provide a damp atmosphere in the house. We fear you will not be able to entirely prevent the evil of which you complain this season, but you may check it considerably.

PRUNING THUJA LOBBI (Subscriber).—You may clip your hedge any time during showery weather from May till September. If cut earlier in spring or later in autumn than the months named the young growths issuing are liable to be injured by frost.

PLANTING BELLADONNA LILIES (Idem).—The proper time for planting is in the summer, as soon as possible after the foliage has withered. You would find this *Anaryllis* quite hardy at the front of a north wall in Kent. When once established the bulbs should not be disturbed. We have seen it flourish on a south border a hundred miles north of London. Make the soil good, and plant the bulbs 6 inches deep.

PLANTS UNDER TREES (Ecc).—Why has Ivy failed repeatedly under your Elm tree? We conclude that it was starved to death by the greedy Elm roots. The exercise of a little care and painstaking for two or three years will enable you to overcome the difficulty. Once get the Ivy established and it will hold its own and prosper. Do this—make rich stations, say a dozen, by stirring plenty of rich manure among the soil; select large strong plants with large balls of earth and roots, or else turned out of large pots; plant one of them in each station on a little mound raised a few inches above the ordinary surface; give frequent liberal doses of sewage or liquid manure during the season of growth; spread rich soil upon the surface around each plant, and as the branches spread get them down among it to induce a prompt emission of roots, so as to render them self-supporting as quickly as possible. The Elm roots will soon lay hold of the soil in which the Ivy is first planted, but by close attention to surface-dressing, pegging, and watering you may bid them defiance, and afford another example of the truth of the time-worn maxim, "Perseverance overcomes all things." *Vinca minor*, the Small-leaved Periwinkle, answers well under trees, so does *St. John's-wort*, but to neither of them would we give the preference for your purpose.

ROSE LEAVES DISEASED (M. J.).—The disease attacking your Rose leaves is the "black spot." It often attacks Roses growing in damp and ill-ventilated houses. It is a fungus; there has been, however, a quantity of red spider upon the foliage of your Roses. Try Fowler's insecticide, or any of the other preparations sold for the purpose of killing insects. An experienced Rose-grower says, if disease of this kind once attack plants the only cure is to cut away the damaged shoots, even if you have to cut the plant down to the ground.

HIMALAYAN BAMBOO NOT GROWING (W. R.).—Your Bamboos which have not grown for two years are doubtless dead. Two years ago many established plants of this Bamboo, growing in the southern counties and in Ireland, bore seed and died. Your only remedy is to plant stout young seedlings.

PROPAGATION OF POLYANTHUS AND AURICULA (Jas. Davies).—After the plants of your border varieties have done flowering do not top them as you propose, but prepare a bed of rich gritty soil on the north side of your wall; take up the plants and divide them into as many shoots as they will afford, which dibble firmly into the bed, and by attention to watering and keeping free of weeds they will become good plants by autumn, when they should be transplanted to the bed or border in which they are to flower next spring. Both plants are easily raised from seed, which should be sown immediately in any sunny garden border.

VARIOUS (Caroline).—If the *Asaleas* are really without foliage the plants have either suffered by neglect in watering or were left out during a frosty night or two in autumn. Do not forget, however, that *Asalea* blossom is frequently so dense as to quite conceal the foliage. A temperature of 89° for Kidney Beans is unnecessarily high. A steady night temperature of 68° is quite hot enough, and if it rise 30° or 30° higher from solar heat in the daytime that would, of course, accelerate growth beneficially, provided due attention is given to watering and a free use of the syringe once or twice daily. The *Rose Souvenir de la Malmaison* is not a climbing variety, but there should be no difficulty in inducing it to put forth vigorous growth and flower freely; it is probably suffering from poverty of soil. Apply a heavy dressing of manure and plentiful waterings. *Maréchal Niel* is somewhat sickly, being much affected by the stock on which it is budded. We have one plant on the common Briar that in five years has covered the side and gable of a building some 30 feet high, and has also spread as far along an adjacent wall; yet others also on Briars and planted with equal care have made no appreciable progress. Dig-in manure about the roots. Give

plentiful doses of sewage or liquid manure, and if it has been starved and is healthy you will soon have strong shoots in abundance. Climbing plants will answer very well in your conservatory facing the north. The effect of the loss of the direct rays of the sun would be seen in a somewhat tardy spring growth, and if you plant *Roses* in it they would afford plenty of flowers, but not early. In most gardens in the south advantage is taken of walls and buildings to plant *Tes-scented* *Roses* facing the north, where they are quite shaded from the sun, in order to obtain a supply of flowers after those in sunny positions have ceased blooming.

SHADING FOR AN EXOTIC FERNERY (W. G.).—A roller blind may easily be applied to the roof of a Cranston's patent house by causing it to run up and down on light iron rods curved and fixed a few inches above the curve of the roof. A natural, graceful, and far preferable shading would be afforded by climbing plants planted inside the house and trained up under the roof. *Lapagerias* would grow and flower well under your ribbed glass, so would *Hoya carnea*; but *Tacsonia Van-Volxemi* and *Passiflora cærulea* would be preferable for the quick production of shade, both making growth with great rapidity and freedom.

IN PÆIDUM ACAULE (H. C. P.).—The seed should be sown very thinly, so that the seedlings do not become crowded in their young state, and about seven plants should be transferred to a 6-inch pot; or the seed may be sown in 6-inch pots and the superfluous plants be drawn out. The plants should be raised in a cool and very light frame, keeping them close to the glass, and eventually removing the lights entirely, except in stormy weather and during drenching rains. Rich soil and abundant supplies of water are requisite for growing the plants healthily. When well cultivated the plants produce a charming effect, but if either starved or drawn they have a miserable appearance. This annual grows and flowers freely in moist soil in the open air.

SOIL FOR MYRTLES (E. G. B.).—Plants that have remained in tubs for many years require rich surface-dressings of loam and manure. Remove with a pointed stick a goodly portion of the old soil, digging down several inches near the sides of the tubs, and replace with a compost of two-thirds of turfy loam and one-third of decayed manure, pressing it down firmly. Over the soil spread a covering of pure manure an inch or two thick, on which soil may be sprinkled for imparting a neat appearance. Do not fill the tubs too full of soil, but leave space for holding sufficient water to percolate through the entire mass. This is a little point of great importance. Filling pots and tubs too full of soil is the cause of many plants being unhealthy.

POLYANTHUS (J. W. Luck).—You have a very good strain of border *Polyanthus*, and you will be able to improve it even more if you persevere and select the seed from the best flowers.

PYRETHRUM AUREUM LACINIATUM (J. C. C.).—This forms a soft and elegant marginal line to flower beds, but we think for producing a golden panel in a carpet bed the old *Golden Feather* is the more suitable. The lacinated variety is paler in colour than its prototype, and does not produce such a dense surface of colour.

HARDY ANNUALS DISTASTEFUL TO SLUGS (J. W. J. D.).—There are few plants that snails and slugs will not devour. We have observed, however, that *Nasturtiums* (*Tropæolums*), *Convolvulus minor*, *Limnanthes Douglasi*, and *Venus's Looking-glass* are not so much eaten as some other annuals; but our practice is to grow what plants are desired and destroy the slugs. When the annuals are aboveground sprinkle a little dry soot over them late in the evening or early morning; this makes the plants very distasteful to the snails and slugs.

ANTS INFESTING FLOWER BEDS (Idem).—Disturb the nest well with a fork after sprinkling guano over it, and again sprinkle the soil with guano after disturbing, or water well with diluted ammoniacal liquor from the gas works. Guano sprinkled in their runs and over the nests will soon cause them to migrate to other quarters.

ANTS (W. L. A.).—Arsenic mixed with honey poisons them, but you had better drive them away by continuing to sprinkle guano over their runs and nests.

INSECTS (W. T. Relford).—The insect ravaging your Rose trees is the *Curculio pyri*. Spread a white cloth beneath the trees and shake them. The insects will fall upon it.

NAME OF FRUIT (J. George).—Birmingham Stone Pippin.

NAMING PLANTS (S. A. B.).—All specimens that we receive are acknowledged, and named if we can identify them.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTURE OF MANGOLD WURTZEL.

SINCE the first introduction of this root for cultivation in this country as cattle food great improvements, by the extension of sorts, has occurred. As being the first growers of them in our own district in 1827 we can well remember the amount of prejudice at that time raised against them, and for a number of years they made their way but very slowly in the estimation of farmers. They were called all sorts of names to bring them, or rather keep them, in disrepute. It was common to hear the observation, "What! are you going to grow those water-bags?" However, as time wore on people began to increase their growth, and they have ultimately found that the prejudice against them was founded on ignorance—viz., that they did not know how and when to use them. Now, however, the tide has set in strongly in favour of the growth of mangolds, and especially since we have the choice of sorts containing more sugar and nutriment for cattle-feeding. The sorts we have now for use

are the Long Red, the Yellow Globe, and Yellow Tankard; there are also some intermediate varieties. The variety called Sugar Beet, although containing a larger amount of saccharine than any other, yet they do not yield sufficient weight per acre to induce farmers to cultivate them in preference to the three first-named sorts.

The Mammoth Long Red is much grown, and prized more for its long-keeping properties than for rich feeding quality. It is adapted only for growth upon rich alluvial soils, but when we have grown it side by side with the Yellow Globe sort it has always deceived us as to weight. It grows so much above ground that it looks to be much the heavier crop, but in our own experience we have never in any instance found it equal the weight of the Yellow Globe sort, which is certainly the heaviest cropping variety we have ever grown; still we think that the Golden Tankard or Golden Intermediate possess higher feeding value than any of the Orange Globe varieties, although we have grown a greater weight per acre of the Globe than any other sort—viz., 55 tons per acre, washed perfectly clean, without the usual adherence of dirt at storing time, which probably in some instances assists in making the extraordinary weights we sometimes hear of, of 80 or 90 tons per acre. There is, however, a growing estimate by farmers of the value of the Yellow Tankard sort, it being a very deep yellow colour inside, very firm, and dense in the substance of the root. To obtain the greatest weight per acre the crop must be sown in the best land, and be sown very early—not later than the last week of April or first week in May. It is of slower growth than the other sorts, and it is our opinion that in case it was required to remain in the land during the winter it may be preserved in our ordinary winters if the rows were earthed-up with the plough in the month of October; it would, however, after a hard frost have lost a portion of its feeding value, like any other root which has been frozen.

The preparation of the land for mangold, if intended to be sown out of fallow, should begin in the autumn immediately after the harvest, and upon strong or heavy loams; the land must be fallowed even if it be quite clean, and after a couple of ploughings, with intermediate harrowings and rollings, it should then be deeply ploughed for the winter, and allowed to take the advantage of alternation from rain to frost. It will then not require to be ploughed in the spring, but merely scarified and harrowed, thus retaining all the advantages of the weather-beaten and pulverised surface; in which case, if yard dung or town manure is used, it should have been applied in the autumn, otherwise the manure used should be artificial guano or nitrate of soda and superphosphate, to be applied by the drill on the flat or level. If only 1 cwt. per acre of guano can be safely used with the drill without destroying all or some of the seed it is best to apply only 2 cwt. superphosphate and 1 cwt. guano by the drill, any extra guano to be sown broadcast and worked in by the first horse-hoeing after the plants are up and strong; if sown earlier it encourages the weeds immensely. In the use of nitrate of soda for mangolds it is best sown broadcast at two or three different times during the growth, the superphosphate to be used being drilled with the seed. It should be always borne in mind that it is difficult to apply the heaviest possible dressing for mangold without reaping the full advantage, for the crop of mangold may not use up all the manure; but it will be satisfactory to know that you will have obtained the best possible crop of roots with probably a residue of the manure available for the succeeding crop of corn. We recommend that mangold when heavy dressings are used should be grown on the bank or stretch upon the light and shallow soils, such as sand or gravel. In applying the manure by this system we usually make up the stretches, then lay out the dung and spread between the banks; otherwise if artificial manure is used it is sown broadcast and the stretches reversed, which buries either sort of manure in the middle of the bank. Upon the home farm we recommend that the seed should be planted by hand, not less than two nor more than three seeds at 15 inches apart, and pressed into the soil with the finger and thumb about an inch in depth, which will take about 5 lbs. of seed per acre. We have succeeded very well by using the hand drill such as is used by gardeners, costing 10s. 6d., which is the most expeditious method of seeding on the ridge or stretch. This will take from 6 to 7 lbs. of seed per acre. The advantages of the ridge culture is that the land can be horse-hoed earlier between the rows, and on light land it deepens the soil available for the growth of the plants. Upon this system we grow the plants 2 feet apart between the rows, and 15 inches apart in the rows. At this distance we find the greatest weight and the best feeding quality can be grown, as moderate-sized roots we consider the most nutritious. Although the heaviest crops are grown by early sowing, it is important sometimes, particularly upon the home farm with only a limited acreage of land under tillage, to take another crop before the mangold. We have grown on various occasions 25 tons of mangold per acre, drilled after midsummer by once ploughing after the hay crop or after a crop of rye cut for fodder; we sometimes, however, cut the rye for straw only, it being very valuable as straw is now selling. The

rye being well out in ear by the middle of May it is often cut, tied into sheaves or carted loose, ricked, and heated in rick for feeding purposes upon the principle of American oat hay. After these crops the mangold generally succeeds well, not being so much injured by insect enemies—such as the fly, wireworm, grub, and white slug—as when grown after a fallow preparation. When the seed has been drilled on the flat so late as the last week in June we have grown fine crops of mangold by drilling them closer between the rows, and also leaving them nearer in the rows—viz., 18 inches by 12 inches; the plants must, however, be taken up at the usual time, although in full leaf and growth, and this is favourable than otherwise, for the roots are sure to keep well in heap in this way, for the early-sown and ripe roots always decay most in the heap. We find that late-sown roots will bear the blows at pulling time, and any injury and bruises to the roots will heal in the heap, but when ripe roots are much bruised they often go off in heap with rotten black spots upon them, which often spreads and endangers the whole bulk. When this tendency to rot occurs the heap should be looked over in the spring of the year, the defective roots picked out, and the heap made up again and rethatched, they will then keep until any time in the summer and autumn.

The feeding value of the crop often depends upon the storing. We recommend that the roots be taken up the second week in October, or earlier if there are many acres to get up. It sometimes happens that the roots are a considerable distance from the homestead, in which case they may be heaped in the field in small round heaps and earthed over, and removed as required for cattle. In the same way they may be what is commonly termed pitted in the field in small heaps when required for sheep to be fed upon the land where they grow; but when mangolds are used for sheep-feeding in the open field they are usually pulled several weeks before feeding, and allowed to lie and get withered. In this way we have seen sheep do remarkably well during the months of September and October, being hurdled off as required, and receiving a little bean or barley meal at the same time. We have on some occasions made capital fat cattle without giving any other root food but mangold, and commencing in October. At this early period many farmers object to use them for fattening cattle, but we have never hesitated during the whole year from using mangolds, for the reason of their great feeding value as compared with Swedish turnips. We have found that 56 lbs. of mangold per day is equal in feeding value to 70 lbs. of Swedes for a fattening bullock; but for either root we always cut them with Gardener's cutter, and mix the bean or barley meal with the cut roots. In this way if the mangold is used in the early part of the season it never purges the cattle. We recommend great care in taking up the roots when intended to be stored in long heaps, the common plan being to make the heap about 8 or 10 feet wide at bottom, and carried up to a point, and covered with seaweed if available, or with straw, and then thatched. After about a month or five weeks the heap should be covered about 6 inches with earth upon the thatch, and it is well to have a few drain pipes set on end at the top of the heap to allow any heated air to escape. Care is required, which is not always properly attended to—that is, when the roots are topped the grass should be twisted off by hand. This will leave the heart bud entire. They will then grow out a little in the heap, which is quite necessary, as they are sure to keep better than when the stems are cut off, as well as the greens, close down to the bulb. Some of the finest mangolds we have ever seen have been grown near the seacoast in the eastern and south-eastern counties. This is to be expected, because it is well known how desirable it is to apply 2 or 8 cwt. of salt per acre on the generality of soils, particularly in the midland counties and inland districts. In cultivating mangolds it is common to attempt growing the roots as large as possible, but instead of growing immense roots, which only astonish women and children, we prefer growing more roots to the acre of a moderate size, believing that roots weighing from 5 to 7 lbs. each are the most nutritious. It must be confessed at the same time that it is more labour to prepare the smaller roots for cutting for cattle. Especial care should be taken to obtain seed grown from a stock which throw but few roots, indeed, only a single tap-root is best. The manure and culture make some difference in this respect.

Before concluding this subject we must remark that the peculiar advantage of mangold culture in preference to the varieties of turnips or any of the cabbage tribe, is that it is well adapted for culture when land is out of chalk. It may also be repeated with impunity, for when properly cultivated and manured we have known fine crops for several years in succession. This cannot be done with any advantage in the case of turnips, cabbage, rape, &c., because in the absence of a fair portion of chalk in the land the roots are sure to become clubbed and go off. Thus we claim a most important value for mangold over and above other roots usually grown on the home farm. This question of absence of chalk is a matter not easily rectified except at great cost, particularly in lands distant from chalk soils. In conclusion, we reckon that upon the generality of soils the mangold crop will not only give one-fifth more feeding value per ton, but one-third more weight per acre than Swedish turnips, thus growing

the cattle food required upon a reduced area and leaving more land for sale crops.

WORK ON THE HOME FARM.

Horse Labour.—It will now be requisite to plant the latest sorts of potatoes. The sooner this is done the better. Potato planting is best done with a one-horse plough, because two horses tread the land too much. Late sorts may well be set wider apart between the rows, every third furrow will bring the rows about 30 inches. This gives room for horse-hoeing, and also requires the one-horse plough to earth-up the lines, which we think is much better done than by the double mould-board plough, particularly at the wide distance, although the double mould-plough answers very well for the early sorts, which are usually planted 2 feet between the rows. In hilling the potatoes with the plough we prefer, instead of hilling both sides of the rows as we proceed, to hill one side throughout the piece and a day or two afterwards to proceed and hill-up the other side of the row. This gives time for any haulm which may have been pressed down by the first furrow to again become erect, and thus the hills may be made more perfect in height and shape, which we consider essential. The horses will now be required to roll-in the clover seeds. We find that much land which would have been seeded at the time of sowing the Lent corn has, owing to the showery weather, not been done. If, therefore, the clover seeds are now sown followed by the ring roller they will most likely be buried properly; if not, the chain harrow will complete the work.

Manual Labour.—Men will now be employed in sowing manures such as guano or nitrate of soda on the corn or grass crops, also in the furrow with the potato sets. Guano we prefer for potatoes, and to prevent its flying before the wind we mix it with some damp ashes. The women will be employed in cutting the potato sets and also planting them when the weather is favourable. We prefer to plant sets of the late sorts of potatoes cut from large tubers. It is also requisite to obtain the most recently propagated sorts which have never yet been tainted with disease. This, together with a change of soil, is the best and most likely method of securing sound produce. The women now should be constantly employed in weeding the clovers, the young wheat, and the early grass land. In planting roots for seed, particularly mangold, it is not only necessary to select the best-shaped roots, but also to plant only those which have the heart-bud uninjured. They will then grow up with a strong single stem; whereas if those roots which had the stems cut close to the bulb are planted they will throw out a number of sprouted stems, which when run up to seed become a tangled mass, which is neither favourable for the produce of seed nor saving it. Mangold seed never ripens evenly, therefore the earliest seed stems should be picked first. In order to facilitate this first picking we prefer to plant the roots in lines 4 feet apart and 18 inches or 2 feet in the rows; and as it is sometimes requisite to be able to pass between the lines, when the seed begins to ripen stakes and small poles or rods are set up on one side of the lines for the seed branches to rest upon. In this way there will be a pathway between the rows for picking the earliest seed stems. In planting Swedes or turnips for seed it is only necessary to select the bulbs for colour, shape, and quality—that is, weight in proportion to size; and in case of planting an acre or more of land it is difficult to prevent the small birds from taking the lion's share of the seed; we therefore, in order to scare them away by boys or men, leave a pathway through the planted ground.

PIGEONS—HINTS TO YOUNG AMATEURS.—No. 2.

ANENT my No. 1 "Hints to Amateurs," writes a valued correspondent, "I have often thought that letters on Pigeons, poultry, &c., for homely and home fanciers would be acceptable to many readers of our Journal; I mean as a change from high-class writings addressed to exhibitors. I think sometimes that writers on home topics forget that there are infant classes ever in formation in the schools of gardening and allied interests pertaining to home pursuits. Do not class writers and class newspapers, in aiming (and properly so) at a high tone, occasionally, or even generally, forget these infant classes? Such a system of teaching would never do in our national schools." Thus encouraged by words with which I wholly agree I will go on, remembering and hoping to help members of those infant classes in the Pigeon fancy—members hereafter to become fully experienced and very clever fanciers. At one of the great Crystal Palace Pigeon shows I was really very sorry for a youth who again and again asked me questions about the birds. He was evidently one of these infant fanciers. I replied to him once or twice, but could not undertake to teach him with my head full of reporting the show, and with not a moment properly to spare. Such there are among our readers no doubt; so put your questions on paper, and I will do my best to answer them in my quiet study in my rectory, as I sit, with eyes now and then raised to look upon a glorious view upon which I have gazed with delight for well nigh a quarter of a century.

Turn we now again to Tumblers. They are among the cleverest

of Pigeons; their little rounded heads have more brain than sloping-forehead Fantails. They are clever in finding their way soon in and out of a new home, clever in following you about even into the house for food. I like to see them put their little knowing heads on one side as if thinking. I have spoken highly of Baldheads, and there is a variety evidently akin to them—viz., the Bearded Tumblers or Beards, so called from a little triangular patch of white reaching from the lower mandible a little way down the throat. Like the Baldhead, the Beard is a white-winged Pigeon. It is an old-fashioned sort, and getting, I fear, scarce; but there used to be about Bristol very well marked, handsome, Black Beards of lustrous plumage and good form. Flying Tumblers have a little gone down since the French and German war brought into great prominence the powers of the homing birds; but it does not suit everybody's employment to walk or drive distances in order to fly homers. There are many who cannot, perhaps, more than once a week get away from their homes; for such the Flying Tumbler is the bird. A fancier of this Pigeon may be within hearing of his shop bell watching the tumbling of his Pigeons, for they soar just overhead. I have known blacksmiths and carpenters and others, whose work was in the yards of their homes, have great enjoyment from their Tumblers. And now for an anecdote of a grimy son of the forge, a master blacksmith, who was a Pigeon crony of mine when I was a boy. I had set my heart upon a certain Red cock bird of the blacksmith's to match with a hen of mine. I found the smith, leather-aproned, holding between his knees a horse's foot, in the act of shoeing him. "What! young gentleman, want me to sell you the old Red cock! Why, I've had him these eight years. I couldn't do it, sir." What boy is willing to give up what he's set his heart on? So I offered the very extreme limit of my purse, but in vain. To make the owner's mind still more firm down came from the air at that minute the old Red cock. He gave a provokingly charming somersault just before he came down, and entered his loft above the shoeing shed in which we were standing. Then I heard his merry rattling coo as he came in to take his turn on the eggs. I felt I was done, and so I was. The worthy blacksmith did not let me have the bird; that provokingly nice tumble and merry rattling coo secured him his home until he died. Another Tumbler friend of mine was a carpenter in a large way of business, and whose birds built high up in the unceiled or partially ceiled roof of his barn-like shop. His were the wildest Tumblers I ever knew; they paired as they liked, and as he had no children they were never petted or handled, but were flown (some forty of them) of a morning, and rare tumbling birds they were. His plan was to introduce a good Black Baldhead or two, and they crossed with his old stock. Thus he kept up the white wings, and then, as a rule, Baldheads were good performers in the air.

Next a word about making the birds fly. Not seldom it is with great difficulty that they can be got to ascend properly, and you cannot manage them if there be some very high building near, for they will settle upon that, and there the idle ones will sit and defy you. But it is not often that you have a high workhouse, or town hall, or gaol next door to you, and if you have not then you can generally manage to get them up. I would say, Do not let them out in winter too soon, but as they come out with a rush clap your hands, or shout, or wave a tall flag and send them up. Then, not unfrequently, failing the morning fly you can get them up in the afternoon before bed time; but this is dangerous in dull weather. The state of the atmosphere has a great deal to do with it; when other birds like to fly high so do Tumblers. Do not pelt or punish the birds, but get them to do their flying as a pleasure and without making them fear you, and so making them also shy and wild, for, unlike the Dragoon, the Tumbler is not a shy bird—almost familiar in some cases. I have known a three or four-o'clock fly in spring and summer be very successful. But give me for real enjoyment a good fly on a bright winter's morning. By the way, Pigeon fancying tends very much to rob winter of its dreariness. In winter the birds (all the fancy Pigeons) are in their most perfect plumage; it is then hard, firm, and bright. In the latter part of winter you are thinking of pairing-up, setting, changing, arranging, mating; so that while the garden is least accessible and interesting the Pigeon loft is especially an object of interest. So I say a Pigeon fancier has an advantage in this respect over many fanciers of other pursuits which can be followed only in summer time.

Besides Baldheads and Beards there are other distinct and prettily marked Tumblers. Thus—Mottles, Black, Red, or Yellow with a certain portion of white on the back, wings, and head, in some cases much white, but better with less white. The Yellow Mottles are very charming, and since flying Pigeons have had a class at our large shows I have seen some beautiful birds of this marking. Various other colours there are, and if the fancier has plenty of room he can enjoy feeding at his feet a perfect bouquet of coloured birds. Whatever colours he has, let him be very particular to have all pearl-eyed birds—that is, white eyes, not dark hazel eyes like Fantails'. The pearl eye the whiter and brighter the better. Also have as rounded and plump-shaped birds as you can get; not flat-backed like common Pigeons, but a certain roundness of back and also full-breasted. If you can get

them to tumble well, having no feathers on their legs, all the better; but often a mere sprinkling of feathers showing a Roller cross goes with good aerial performances, but the true Tumbler has little coral unfeathered legs and feet. The modern Tumbler of the Birmingham type is a larger bird with very heavily feathered legs, and now bred in very pretty colours—Mottles, Saddles, &c.—a coarser bird than the old dapper Tumbler, but a pearl-eyed and handsome, yea noble bird nevertheless, though the head and beak are certainly too long. I own a strong preference for the older class. In buying flying birds you must mind and not get degenerate, high-class, or short-faced birds, which are pretty, very, but not strong enough to fly well or for any length of time, and they very very rarely tumble at all, though I have once seen a coarsely bred Almond tumble admirably. In my next paper I will speak of the sort of home best suited for Tumblers, of their food, and of their indoor management.—WILTSHIRE RECTOR.

POND MAKING.

PURE water must always be considered a necessity for cows in

Fig. 51.—PLAN OF POND.

A. Paved entrance from the north | B. Cross rails at lowest part of pond
C. Body of pond.

B. Paved entrance | D. Cross rails
E. Lowest point of pond

a butter-making dairy; it, however, often receives but little or no attention, the cows being allowed to drink anywhere, and very often at ponds tainted by the drainage from the farmyard. The question then arises how pure water is best to be obtained and made available. Where there are running brooks and rivers there will be no difficulty in providing water (although there may be) by securing a safe and convenient watering place where the animals can drink at all times without danger or difficulty. Where park or pasture lands are situated at high altitudes on chalk or stone formation it may be necessary to make a pond. In that case we propose, as the best plan, to make a pond near to a high road or farm road, where in case of a sudden thunderstorm a large quantity of water may be accumulated and preserved for future use. The excavation may be made 4 or 8 feet deep, of any required width, and surrounded by a single rail and high hedge of quick and privet to prevent evaporation, and the approach to the pond should be pitched or paved with flint or flagstones. In order that the cattle may drink without entering the pond, brook, or river the entrance should be guarded by two strong rails across it, so that when the water is low they may drink through the rails without entering the pond or brook. In the case of ponds they may be puddled with clay or concreted at bottom, which the entrance of the cattle may tread and injure, and it is in this way only that the last bucketful of water in the pond can be obtained by the animals without injury to the pond or to themselves in the brook or river. This plan of pond-making may also be carried out as a double pond available for two fields, or at the corner where three or four fields meet, the ditches or drainwork from each acting as feeders to the pond, or when full acting as waste drains to carry off flood water.

(To be continued.)

VARIETIES.

MESSRS. CARTER & Co. state that the lawns at the Paris Exhibition that were sown with their seed on the 8th of April received their first cutting with the mowing machine on the 29th of April, and that the French authorities are so impressed with the quickness of growth of the grasses that they have placed a large additional portion of the Exhibition grounds in the charge of Messrs. Carter, who have now sown about three-fourths of the grounds with their seeds.

FARMERS' prospects are, says the *Mark Lane Express*, certainly brighter to-day than they have been at this period of the season for several years past. The dark green of the wheats gladdens the eye, and the strong and multiform tillering of the plant is also a very promising sign. Even the thin pieces are filling up wonderfully, and if we get what is called a "following season" a good crop of the principal cereal may be regarded as certain. However, until the blooming season has passed we can have no real security for a good yield. Spring corn of all kinds also looks well. Grumbling just now is at a discount.

ORIGIN OF POULTRY.—Asia is the home of our most valuable domestic fowl, with the exception of the Turkey; at least, to that continent must we look for their earliest domestication. The Goose and Duck, however, appear to be indigenous to no particular quarter of the globe. But the genus *Gallus* is undoubtedly Asiatic, and it is to this day found in India and Java in a wild state, and affords as much sport to the huntsman as does the pheasant in England or the prairie fowl in this country. Undoubtedly all our varieties come from the *Gallus Bankiva*. Although the colours and markings of the wild fowl are nearly uniform, there is sufficient variety to account for the many changes of which, under domestication, the species is capable. —(*American Poultry World*.)

A GOOD hint to fowl-raisers, says our contemporary above quoted, is afforded in the fact that all wild birds feed their young upon animal (insect) food, even if berries, buds, seeds, &c., form the natural diet of the parents or adults of the same species. Thus young chickens will not thrive so well without it as they will if supplied with animal food in some shape. Earthworms are capital for very young chicks. Cooked meat chopped up fine with boiled rice and potatoes is a very nourishing and acceptable dish for them when young. But not too much of this—nor must it be given too often, otherwise they scour from the excess of the meat feed. A little two or three times a day will help them until they get to be six weeks old. By that time they will be strong enough to run in the fields and grass, where they will gather a more natural supply of this kind of food, and generally plenty of it.

THE French Government, realising that national and individual prosperity are dependant upon the development of agriculture, have introduced a bill in the Senate

making it obligatory to teach the elements of agriculture and horticulture in the thirty thousand primary schools of the nation.

— A LUTON correspondent, writing in reply to Mr. Pettigrew, states that bees in his district have fared very ill during the past winter. In September, 1877, he made up his stock to 105 hives, all fed-up bees, and now out of the 105 he has ninety-one hives doing well.

— We learn from an American source that a good and cheap varnish for general use, and one which dries in a very short time, may be made of the best wood naptha one pint, gum shellac 2 ozs., gum sandarac 2 ozs. Pound the ingredients in a mortar, and pour on the naptha, shaking it up often. When dissolved filter through fine muslin, and the varnish will then be fit to use. If too thick add more naptha.

— IN Thuringa, Germany, says the *Prairie Farmer*, over 1000 tons of dried beetroot leaves are annually passed off as genuine tobacco. These same leaves, as well as those of chicory and cabbage, are largely used for a similar purpose in Magdeburg and in the Palatinate. The "Vevey" cigars, so much favoured in South Germany, are composed of cabbage and beet leaves, deprived of their natural smell and taste, and subsequently steeped in tobacco water for a lengthened period.

— THE total number of animals imported into Great Britain from all countries in 1877 were as follows:—From European countries we received 179,236 cattle, 848,815 sheep, 18,745 swine. From the United States and Canada 19,187 cattle, 28,395 sheep, 810 swine. From the Channel Islands we received 2,688 cattle, and 2 swine; and from other countries 5 cattle, 449 sheep, and 17 swine. From Ireland 649,441 cattle, 680,774 sheep, 585,427 swine. Making a total of 2,958,441 animals, against 3,226,948 in the previous year.

— THE first mention of butter is that of Herodotus, where, in describing the Scythians, he says, "These people pour the milk of their mares into wooden vessels, cause it to be violently stirred or shaken by their blind slaves, and separate the part that arises to the surface, as they consider it more valuable than that which is collected below it." Soon after the death of Hippocrates we read that the Greeks thought the butter which the Thracians ate a wonderful kind of food. The ancient Ethiopians appear to have used butter as food, while the ancient Germans were also butter-makers.

— WHERE a system of feeding cows for milk prevails that is altogether artificial and unnatural the product can neither be healthy nor satisfactory in quality or condition. Where brewers' grains or distillery wash forms a chief part of the cow's food the animals are unnaturally stimulated, and under such a stimulus large quantities of milk of inferior quality are secreted, the cow quickly becoming worn-out and diseased in consequence.

— "THE greatest mistake," says Mr. Falconer King in his report of the analytical work of the year, "which I have ever seen committed in connection with the employment of lime is that of mixing it with manure before application. In these days of enlightenment it is almost incredible that such an egregious error as this should be committed. When farmyard manure, at least after it has been kept for some time, is so treated with lime it is almost entirely destroyed, and the value of many other manures by similar treatment would be very much lessened. Lime should never be allowed to come in contact with the manure at all, and if it could be arranged conveniently these two substances should be applied to the land at different times."

— IN these days of "big things," says an American writer, our small breeds of poultry seem to be falling into disrepute. Golden-spangled Sebrights give larger eggs in proportion to their size than any other breed with which I have become acquainted. Moreover, under the present mode of buying and selling by counting the price received for these eggs is the same as that for any others. The birds can be allowed the range of the garden and lawn, where they are very useful insect-destroyers, doing but little damage as compared with a 12-lb. Brahma, which scatters a hill of potatoes with one or two strokes of its great clumsy foot, or devours a large head of cabbage at one meal. Some other breeds are preferable for table, but for clear profit in eggs Spangled Sebright Bantams are surpassed by none.

HONEY-PRODUCING DISTRICT.

"WILL you ask your correspondent, Mr. Pettigrew, to tell us what parish he considers the best in the United Kingdom for honey-producing (for a large number of stocks), everything considered?"—A KILKENNY BEE-KEEPER.

This question is one that naturally arises in the minds of those who contemplate bee-keeping for profit on a large scale; but no one can tell which is the best parish or neighbourhood in Great Britain and Ireland for honey. In considerations of this kind there is no place for the superlative degree, for we can never get beyond "good" and "better" localities for honey and bees. The last words of our correspondent's question, "everything

considered," cover a great deal—viz., pasture, climate, and a market for the produce. Many places in Ireland, so far as pasture and climate are concerned, cannot be well surpassed for bees, but there the markets are not favourable, and the price of honey is low. For thirty years I have admired the honey that came from the neighbourhood or county of Dublin for sale. In some seasons when we have had bad harvests of honey in England large quantities of excellent honey and comb came from Ireland. Swarm hives containing 7, 8, and 9 stones of honeycomb each have arrived in Liverpool with their combs unbroken and in good condition. The climate of the south of both England and Ireland being warmer than the north must be better for bees, all other things being equal. The pasture, climate, and the records we have seen of successful bee-keeping in the south of England have made us form a high opinion of Devonshire and its neighbour counties. The grand supers of Mr. Fox, filled at Kingsbridge in Devonshire, are evidence enough of what bees can do in Devonshire under good management; and Mr. Fox informed me some years ago that he does not remove his bees to the moors.

The results of bee-keeping in many places of Scotland have been very satisfactory, and prove that under good management bee-keeping even in the north is profitable. Glasgow is in our opinion the best market in the world for honey. England is a better fruit country than either Ireland or Scotland, and is the refore, generally speaking, better for bees during the spring months. England, too, has more sycamore and lime trees, and grows more field beans than Scotland, and these yield honey in abundance. But probably the grass fields of Ireland and Scotland are better sprinkled with white clover than those of England, and it is well known that white clover is the queen of honey flowers in this country. Heather, which abounds in Ireland and Scotland and many parts of England, comes into flower late in the season (August), and yields large harvests of honey of a strong and peculiar flavour; but heather is more useful to the bee-keepers of the north than to those of the south, for in the north the summers are shorter, and in autumn the second crop of white clover does not yield honey as it does in the warmer climate of the south. The south, in our opinion, is better for honey than the north, "everything considered."

I do not know what our correspondent means by "a large number of stocks," for this may mean twenty, fifty, or five hundred hives; but I will here say that thirty strong hives are enough to stand in one garden, even in a good locality. When stocks are multiplied beyond thirty it is better to spread them abroad one or two miles apart, say twenty hives in one place and twenty in another, thus giving the bees a wider pasturage.

A strong hive in the midst of the season for honey contains about fifty thousand bees, and twenty of such large communities will pay many visits every day to the honey-producing flowers around them, and carry a large amount of honey.—A. PETTIGREW.

BEEES FOR PROFIT.

I WISH to write a word of encouragement to the despairing bee-keeper. I read with much interest Mr. A. Pettigrew's remarks on page 312, and I will give him a little of the information he seeks, the result of my personal experience of last year's bee-farming. I am an old apiarian, and am not easily discouraged by climatic changes or the consequences resulting therefrom; if I were, my experience of the last two years would damp my ardour somewhat.

Some twenty years ago I set myself to work out the problem whether bees under careful management could be made to pay. Hobbies as a rule are rather expensive luxuries and rarely if ever pay; but I was certain that bees are an exception to this rule, and that a cottager with a little enterprise and who had sense enough to avail himself of the practical suggestions of others might easily gain his rent by his bees. If my memory serves me faithfully I spent that year £20 in the purchase of stocks and appurtenances, including hives, supers, and wood for houses. It was a needlessly large outlay for the experiment, but stocks were dear that year; still when the season closed I found I had recouped myself my expenses great as they had been, and had an apiary which was the admiration of all the old bee-keepers hereabouts. They flocked in from the surrounding neighbourhood for explanation and advice. I told them that I never killed a bee, I had never sulphured a hive in my life, nor have I up to this day. I told them further that I fed them when they were hungry whether in summer or winter; that I gave them clean, sweet, and dry hives to live in, and frequently changed their boards, scraping them with a bit of glass to make surety sure; that I protected them from the weather, fed them from the top of the hive, and wrapped them well round in the early spring with haybands or sacking to keep the brood warm, and gave them plenty of water in breeding time. The question again and again arose, "What do you do with your bees if you do not kill them in the autumn?" Do with them! Why, I join two or three hives together, and that with very little trouble. "Then they want feeding?" Well, feed them. Sugar is 4d. a pound, and honey is worth a shilling. Where is the loss?

I have found after many years' experience that the old estimate of honey seasons is fairly trustworthy—that out of seven consecutive years three are good, three are but indifferent, and one is decidedly bad. The last season was by far the worst in my recollection, but yet I have gathered from it a very useful practical lesson. If any of our old-fashioned friends who deem it absurd to feed bees happen to glance over these lines I hope they will not miss the lesson. At the close of last April I had twelve stocks of good average weight, and certainly very promising. Well, I secured but one swarm from these twelve good stocks; one I am told escaped and was lost. Early in June, as the rest evinced no disposition to swarm and were hanging about the hives wasting time, I supered the whole, hoping that I should get some honey though I had failed in swarms. To my astonishment in the autumn I found that only two supers were properly filled and thoroughly good, and that two others were filled but were not marketable. The other nine supers were empty. When I removed the supers and weighed the hives I found that there was scarcely one that could reasonably be expected to stand the winter. Many had little or no food at all; so I began feeding, hoping that frosty weather would not ruin my prospects, for I dread dysentery after frosts more than a deficiency in stores. Thanks to the mild winter I have brought eleven stocks out of the thirteen through their troubles. Of course I have been able to feed most of them all through the winter, and I have fed them. To have stinted them would have been wretched policy, for no living creatures so well repay for their keep as bees. My only regret is that I did not look more attentively to the two hives I have lost, for I am persuaded I might have saved them also. The food I give them answers very well in seasons of great scarcity when quantity is the *sine quâ non*. To each pound of loaf sugar allow half a pint of water and boil them for about three minutes. If you boil any quantity, say 5 lbs. of sugar, add after boiling a wineglass of rum, and a tablespoonful or two of strained honey if you happen to have any by you: this mixes well together and the bees like it. I always feed from the top of the hive except I am giving barley-sugar: this I give from below. I commonly use those small preserve jars or marmalade pots, the top of which I cover over with a little old muslin which is useful for no other purpose. In this way I have managed to give my bees nearly a hundredweight of food since last October.—C. LILLEY.

BEEES AT THE PRESENT TIME.

MR. PETTIGREW, on page 312, having asked bee-keepers to give their experience with bees during the last few months, I beg to remark that out of forty stocks I have lost one only, but came near losing three of my strongest in February, owing to their having bred so freely during the mild weather we had. Fortunately I happened to look at one and found half the bees dead, they having consumed all the food on one side of the hive, but the queen was alive, and sufficient bees left to continue breeding after clearing out the dead ones; so after finding out the state of this one I overhauled the entire lot, and found two others in the same plight, and one of those a stock with an imported Ligurian queen. She had been introduced to a stock of hybrids in the autumn, and had bred so much that they had eaten all the food on one side of their hive, and among the dead bees was the queen; so I joined the remaining bees to a stock close by, and they are very strong at the present time, as likewise are most of the forty stocks.

I may just remark that all my bees are Ligurians and hybrids. I keep them in bar-frame hives, and I usually in the autumn take old queens away and give the stocks young queens, and I invariably find that young queens continue to breed later in autumn than old ones.

On the 25th of April a gentleman from Kenilworth called to see me, and I asked him how his bees had wintered and stood the cold winds of this spring. He says he has ten stocks all very strong, and has not lost any; in fact, they are quite full, particularly a Woodbury bar-frame hive, into which he put a swarm last year. He has one other bar-frame hive, and the rest are straw skeps, and as he wants to prevent swarming as much as possible he likes the frame hives best, because he can open the top of the hive and attend on supers, but the straw skeps with the central hole he is afraid they will bother him by swarming. It appears to me, as far as I can learn, that bees have wintered well round here (Mid-Warwickshire), and that the outlook for the present year is encouraging.—A. W. B.

As regards our neighbourhood, which is a few miles from Leamington, I have scarcely heard of a stock dying this spring, and a few miles from here I looked at some more than a month ago, and they were cram full of bees, and had plenty of honey left to carry them through.—A. WARWICKSHIRE BEE-KEEPER.

OUR LETTER BOX.

PROFITABLE FOWLS (S. X.).—Without knowing your requirements more definitely it is not easy to answer your question very precisely. For general

use both for table and laying we recommend Dorkings, where soil and situation are fairly warm. Dorkings crossed with Game produce stronger chickens than the pure breed, and excellent for table. As layers of large eggs we recommend Brahmas; they may also be crossed advantageously with Dorkings, the produce being excellent as layers and mothers. When eggs alone are required we should, of course, recommend some of the varieties which do not sit. None can be better than Black Minorcas, or Leghorns either Brown or White.

EGGS (R. B.).—If there is a fecundated germ in them a male bird must have been with the hens.

TRANSFERRING BEES (W. H. A.).—You cannot transfer your bees into bar-frame hives at a better time than when flowers are plentiful, say during the early swarming period about the end of May or early in June.

GREEN PARAKEET'S EYELID ULCERATED (Twenty-years Subscriber).—Bathe the sore with lukewarm water once a day for a week, so as to thoroughly cleanse it of the purulent matter. Afterwards, with a small camel-hair brush, carefully anoint around the part affected with an ointment made up from about five grains of lunar caustic to half an ounce of fresh lard. Apart from the ulcer the bird may appear in good health, still there may be a defect in the bird's system, therefore the outward application can be assisted by carefully administering to the patient a couple of drops of castor oil. When castor oil is given to a bird the services of a second person may be called in for the purpose of placing betwixt the base of the mandibles a thin skewer or bodkin whilst the oil is dropped in the back part of the mouth, care being exercised that no oil be spilled upon the feathers. If your Parakeet will partake of a br ad-and-milk diet add to it a teaspoonful of a decoction of dandelion.

DORMOUSE (Lilian).—Your feeding it with nuts and fruits is correct. We do not know how long it usually lives.

REMARKS.

24th.—Fair morning, but dull afternoon, clouds cleared at sunset; fine evening.
25th.—Fine sunny day, but cold wind; starlight night.
26th.—Very bright sunny day; fine night.
27th.—Another bright sunny day, rather overcast and dull between 4 and 6 P.M.; very fine evening.
28th.—Calm and pleasant morning; fine day, slightly overcast at intervals; very fine evening.
29th.—Fair day and much warmer, but cloudy damp evening.
30th.—Warm morning, but rather dull afternoon; bright evening, fair.
Barometer rather higher than last week, temperature about 2° higher. Week on the whole fine and dry, but cold winds rather prevalent.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 1.

TRADE is still very quiet with a good supply of early fruit, such as Grapes, Strawberries, Peaches, Figs, Cherries, and Melons. Asparagus from the open is now showing itself, and the first Gooseberries have arrived this week. Prices are generally lower.

From observations taken near London during forty-three years, the average day temperature of the week is 63.0°; and its night temperature 40.8°.

CUTTING ASPARAGUS.

CUSTOM exists in many districts of systematically chopping off the small young shoots of Asparagus whether they are wanted for use or not. This practice is continued until the end of June, or at least quite until the close of the Asparagus-cutting season. The system is not only practised in many gardens, but is occasionally recommended by writers in the horticultural press. I do not wish to assume a dogmatic tone and say that in all cases the practice alluded to is wrong, but I wish to express my belief that it is, as a rule, much more pernicious than beneficial. If any cultivator entertains a contrary opinion it is important that the reasons for holding it be published. I have seen the practice alluded to advocated, but have never yet seen a reason advanced for such advocacy.

In order to be consistent I will submit the reasons that have induced me to abandon a practice which I have seen followed by generally good gardeners, and which I was obliged to adopt when in a subordinate position in half a dozen different gardens. My first reason for not cutting the spray or sprue is a physiological one; my second practical.

First, If a plant of any kind is denuded of its foliage the health of the plant is impaired: it is indeed only by promoting a free and healthy growth of foliage (and I may incidentally remark that it can only be healthy when exposed to full light and air) that a satisfactory plant can be produced. The seed of a plant formed above ground and the crown or growing part of a plant that is formed in the soil are alike storehouses of food; the one to supply a future plant, the other to prolong the life and increase the growth of the plant already existent. The source of the food is the soil and the air; vehicles for producing it and manufacturing it are roots and leaves. I will not copy from books and detail in a mock scientific manner how the roots of plants absorb different ingredients from the soil, and how the leaves decompose them and render them nutritious by changing the crude juices into organic substances. It is sufficient to know that that is the fact.

The next point to take cognisance of is that the substances formed in and by the leaves are stored up in different parts of the plant, little or nothing of them remaining in the leaves. Thus in ligneous plants—trees—the stem, and in tuberous plants—as Potatoes—the tuber is the storehouse, and in caulescent plants—Asparagus—the crown is the food-preserver of the plant. Without leaves there can be no food stored up, any more than crude juices out of which it is produced could be provided without roots. The cutting-off the heads of young plants, therefore, is only a little less injurious than cutting off the roots. I am aware in the case of Asparagus that if the whole of the heads are cut off in a young state succeeding growths will issue, because there is a sufficient residue of vitality in the crown to promote a second growth; but that growth is weaker, not stronger, than the growth preceding, and is produced at the

cost of weakening the plant. Even Peas, if the shoots are cut off immediately they appear above ground and before the parent seed has decayed or become exhausted, will produce a second growth from the residue of stored food in the seed; but such forlorn-hope growth is necessarily weak and unprofitable. The above is what I term my physiological reason for not cutting the young shoots of Asparagus except they are required for special purposes—as I am sorry to say so many of them are—by the cook.

I will now submit some practical evidence that the custom alluded to is wrong. In nearly or quite all instructions on Asparagus culture we find it urged that the growths or heads should not be cut in a young state until the plants are three or four years old. Why is this? Obviously because cutting would weaken the plants; whereas by permitting the shoots to grow the plants attain strength. I am not aware that the correctness of that advice has been questioned. Assuming it to be sound, I want to know how it can be right to leave the small young shoots of new plants uncut, and at the same time wrong to cut the small young growths of older plants? I well know that in hundreds of gardens the habit is in one case to cut and to leave the shoots uncut in the other; but I fail to see that the practice is either rational or logical. I have for many years made it a practice of only cutting such small shoots that were required for cooking purposes, leaving all I could to grow unchecked to gather and prepare food for storing in the crowns for providing future and larger heads. If the practice had been wrong the beds must have deteriorated in value, whereas the contrary is the case. Although the beds are as old as I am, and I am approaching half a century, they are more profitable than ever. One important element in contributing to their prolonged productiveness, I am persuaded, is the practice of not cutting the small shoots.

As bearing on this subject, and which indeed suggested these notes, the following letter has been forwarded to me by the Editors with an intimation that they had replied to the question, but with characteristic editorial reticence did not communicate to me the nature of their reply. Here is the letter:—

"A gentleman having informed me that for some years he had very poor crops of Asparagus, though much care had been bestowed on it, until he adopted the plan of leaving on—i.e., not cutting the weak shoots in May, I take the liberty to ask your advice before allowing the weak thin shoots to go to leaf and seed, as it is so contrary to the usual mode—viz., continuing to cut till the middle of June."

The receipt of the above letter I interpret as an intimation that the question to which it refers is worthy of examination and discussion: hence I have given some reasons why I have adopted the practice of not cutting the "weak thin shoots of Asparagus in May."

I have yet one other reason for leaving the young shoots, and it appears to me a cogent one. Nine years ago I sowed a few short rows of Asparagus for the sole purpose of testing the question at issue. A portion of the bed has been systematically cut until the middle of June, another portion has had only the strong shoots cut, and a third portion has

not been cut at all. The result is that where severe cutting has been practised the bed is the weakest, and where it has not been cut at all the plants are the strongest. That experiment has satisfied me that the custom of cutting off all the young growths in May is not a sound one.

I may now glance for a moment on the other side of the question. The gentleman whose letter I have quoted I assume to be under the impression that leaving the shoots to produce and ripen seed must have a tendency to exhaust the plants. Philosophically speaking he is right, practically he is wrong; yet theory and practice do not clash here, for the sufficient reason that the small thin shoots do not produce seed. Even when the stems are strong not more than one in ten produces seed. If all the young small shoots produced seed then we might well hesitate before permitting them to grow, because much of the strength of the plant is appropriated by the fruit and seed vessels; but since the young growths alluded to seldom perfect seed, no injury on that score can arise by permitting them to grow.

As the subject of cutting *Asparagus* is one in which a vast number are interested, and as the time is opportune for discussing the pros and cons of that matter, I shall be glad if other cultivators will communicate their experience, and especially if they can advance sound reasons for adopting a practice contrary to that now advocated of permitting the small shoots to remain uncut.—A NORTHERN GARDENER.

FRUIT PROSPECTS.

DURING recent years, owing almost entirely to severe frosts occurring during the blossoming period, the dearth of English-grown fruit has been a source of great loss to the owners of gardens and orchards, and also to the consuming public generally, for importations of foreign fruit, valuable as they are, cannot compensate for the absence of home-grown produce. More than usual anxiety is therefore evinced as to the prospective character of the fruit harvest of 1878. We have from time to time received many letters from various districts relative to the great wealth of fruit blossom, and the majority of them are hopeful in tone. Some of these letters we now publish, as they reflect the opinions of competent men and close observers over a great extent of country—indeed of nearly all the districts of England, as well as Ireland, Scotland, and Wales.

ENGLAND.

It will be appropriate first to refer to the fruit prospects in the Royal Horticultural Society's garden at Chiswick.

The fruit trees, for which this garden is justly famed, have usually been more attractive by their general health and admirable training than remarkable for heavy crops of fruit. Blossom there has been in abundance, but it has frequently succumbed to the inclemency of the weather; this year, however, with the exception of Pears there is a reasonable prospect that a good supply of fruit will be produced. Chiswick is pre-eminently a garden of utility; there is little or nothing picturesque about it, but now the rich profusion of Apple blossom renders it decidedly beautiful. The long lines of horizontal cordons are wreathed with blossom, and the hundreds of handsome pyramids are masses of delicately-tinted flowers. The foliage also is expanding freely, and only frost of unwonted severity can prevent a golden harvest of this the most useful of hardy fruits. Particularly interesting and not less instructive is it to note the effects that different stocks exercise on the same variety of Apple. Stocks of the English and French Paradise, the Doucin, the Dutch Paradise, Scott's Paradise, Rivers' Broad-leaved, Nonsuch, Miniature, and Pigmy Paradise, and the Crab are grown so as to display their natural habits and character. On each kind of stock scions of the naturally late-bearing Blenheim Pippin were worked three years ago. The results are most marked. The trees on the Crab stock have grown strongly, but have not produced one blossom; a tree on the Dutch stock has produced just one truss; trees on the English Paradise have each half a dozen blossoms; those worked on the Doucin and the French Paradise, have grown less freely, but are densely covered with bold flowers, and the trees though small are remarkably healthy. Rivers' Pigmy and Broad-leaved Paradise also flowered freely. Scott's Paradise has produced neither free-growing nor full-blossoming trees. The French Paradise stock is the most precocious of all, and in consequence of the early-sap movement when frosts occurred most of the ungrafted stocks which were planted out as specimens have been killed;

but there is no instance of the stock being killed after having been grafted, and it is noteworthy that the natural precocity of the stock is not imparted to the scion. All the trees of the variety named blossom at their natural time and simultaneously on the whole of the stocks, a fact of some importance. These useful experiments have been conducted with great care, and all the stocks and grafted trees have been grown together and under precisely similar conditions.

Plums at Chiswick have blossomed profusely, and a fair set of fruit is observable on many trees. The soil grows the trees fully too vigorously, and in order to accommodate the requisite number of varieties free pruning has to be resorted to, and Plums not infrequently fail to set when the growth of the trees is luxuriant. Woolston Gage on the wall seldom fruits in this garden.

Cherries, like Plums, have blossomed profusely, and a good crop is anticipated. Particularly noticeable are the Morellos on the north wall. The trees are not closely secured to the wall according to the usual custom, but the sprays are permitted to grow from the wall in a semi-natural manner, only the larger growths being nailed-in. The result is prodigious crops of fine fruit, and, what is of special importance, it is clean. The crop this year promises to be very large.

Pears have blossomed moderately, and even if all the blossoms set there cannot be more than half a crop.

Peaches and Nectarines.—The south wall, on which is trained an extensive collection, presents quite an extraordinary appearance. The trees are diagonally trained cordons. The growths are not closely pinched and spurred, but are thinly trained to the wall on both sides of each main stem. The set of fruit is enormous. Quite nine-tenths will have to be removed from many of the trees. The foliage is as clean and healthy as the shoots are fruitful. The trees have only had the protection of a double thickness of herring nets. It is a splendid wall of fruit, and the crop at the present time cannot be surpassed by any in the kingdom. Mr. Barron pointed out a slight mistake that was made in planting the trees. The cordons were to have been 2 feet apart when trained to the wall, and to effect this when trained diagonally they should have been planted more than 2 feet apart. The trees referred to, although planted 2 feet apart, are not more than 1 foot 9 inches distant when brought from the vertical position and trained slantingly. This is a little fact worth mentioning, as it may not occur to all planters of trees that just in proportion as the cordons are depressed from the vertical line so will the space between cordon and cordon be diminished.

The crop of Peaches, Nectarines, and Apricots in the unheated orchard house is remarkably fine, and thousands of fruit will have to be removed.

Small fruits promise to be a moderately full but not a heavy crop.

If the present favourable weather continues Chiswick will be full of fruit this year, and the trees are unusually free from insects. This is probably attributable in a great measure to the severity of the weather at the close of March and beginning of April, which no doubt checked the increase of aphides considerably while it did not perceptibly injure the trees.

Contiguous to the gardens above referred to are some extensive fruit gardens and orchards. The Apple trees in the grounds of Mr. Mills and Mr. F. Dancer present a magnificent appearance. The grounds of the former cultivator are limited in comparison with those of the latter, but it is surprising to see the wonderful thrift and excellent cultivation of both small fruit and flowers beneath the fine fruit trees now densely wreathed with blossom. Mr. Dancer, a fruit cultivator of admitted celebrity, has a magnificent display of Apple blossom. The acres of Cox's Orange Pippin are worth a long journey to see. The trees are planted about 9 feet apart and are about 12 feet high. They have never been pruned nor pinched, but have had the branches thinned out when necessary, and the result is model trees of graceful contour and crowded with blossom from centre to circumference. It is not too much to say that by no system of pruning could so much fruit be produced in a given time as these handsome naturally grown bushes are capable of yielding. Small's Admirable is also extensively grown and has an excellent display of blossom—such, indeed, as could not have been produced had the trees been pruned, for this good Apple, like a few others, has the habit of bearing heavily at the extremities of the branches. All the varieties of Apples are richly draped with blossom, and genial weather continuing a great crop of fruit is anticipated.

Plums have shed their blossom. Thousands of trees are

grown, and on many of them good crops of fruit are setting. The most prolific varieties are perhaps Mitchelson's and Gisborne's. Rivers' Prolific, Victoria, and Prince of Wales also promise well. Belle de Septembre is also noteworthy by its Lombardy Poplar-like habit of growth; it is setting a good crop of fruit, and is a valuable late Plum. Later still is Sandall's Plum, the only variety that grows into a real timber tree; it is setting a good crop. The Plum blossom was more or less injured by the frost of late March and early April, and the crop consequently will be "patchy," some trees being heavily laden but others barren. A moderately good crop will probably result, but not a heavy one.

Cherries.—These are not grown largely except Morellos, and the bush trees of these are perfect pictures. They are 8 to 9 feet high and through, and are "white as a sheet" with blossom. They have a beautiful appearance now, and will be equally beautiful in the autumn when heavily laden, as they promise to be, with crimson fruit.

Pears.—Many of the trees produced scarcely any blossom; others had a moderate show, but the fruit is not setting well and the crop will be a scant one—almost a failure. Gooseberries and Currants promise to be a moderate crop in this district, and Strawberries are showing freely.

The following also refers to the London district:—

"Apricots bloomed freely enough, but the weather at the time was most unpropitious and killed nearly all the flowers; except in very warm and sheltered positions very few fruit have set.

"Peaches and Nectarines on walls are fairly set, and more than an average crop may be looked for.

"Pears, Plums, and Cherries, with very few exceptions, have an abundance of bloom, and are just now very effective indeed.

"Apples are not fully out, but are looking very promising. Kerry Pippin and Keswick Codlin are amongst the forwardest, while Cellini and Cox's Orange Pippin are only just showing for bloom.

"Strawberries are throwing up their flower spikes plentifully, but Gooseberries are generally scarce. If late frosts do not visit us again more than a fair average of fruit of all kinds except Apricots and Gooseberries is anticipated.—J. W. MOORMAN."

The following refers to an important fruit district still further south:—

"Looking at the fruit crop as a whole in Kent there appears every probability of a large one, but when we examine the different kinds we find that some fall short. Cherries have bloomed well, and with the exception of a few early sorts will yield a large crop if the weather is suitable. Plums, with the exception of the Diamonds, which in some of the low-lying districts have been cut by the frost, also promise a large crop. It is too soon, however, yet for us to rely upon a large yield, as the May frosts are usually fatal to Plums.

"Apples are not yet sufficiently forward in blossom to ascertain the probabilities of a crop, but from the appearance of the trees we may expect good results to follow. The Pear blossom is very uncertain; in some parts good, in others almost a failure. Damsons apparently will be very prolific.

"The Gooseberries have been struck by the frost in many districts, and "Yellows" and "Bobs" will be a very short crop. Black Currants are at present uncertain, but there will not be a large yield. The Cob Nut trees will not be very full of bloom, partly, I suspect, owing to the large crop of last year. Peaches are doing well, but Apricots are a failure. I shall be better able in a few weeks to give you results, as at present one night's frost would do an immensity of damage. The general appearance of ordinary farm crops is very good, and we may expect a good yield of corn and hay.—LEWIS A. KILLICK."

From a more westerly district (Sussex) we have the following:—"Sharp frosts and cold biting winds from the north-east were so prevalent at the end of March and the first fortnight of April that much mischief was done to some of the blossom. Peaches and Nectarines upon open walls suffered severely, many of the wood buds just bursting into leaf being destroyed with a heavy per-centage of blossom—too heavy to admit of more than a slight crop of fruit being matured this season. Apricots have suffered even more severely. There will be no fruit where the wind has not been quite shut out, but wherever Apricots, Peaches, and Nectarines have enjoyed the protection of unheated glazed screens the crop is abundant.

"Plums, Cherries, and many sorts of Pears are 'clouds of bloom'; a few of the earliest Pears have, however, lost some blossom by frost. Apples have suffered from the attacks of

tomtits and bullfinches, yet enough blossom is left to afford promise of a tolerably full crop. The Filbert and Nut crop is a failure; female blossom was plentiful enough for another heavy crop, but all has succumbed to the frost. Last year we had plenty of Nuts but very few Apples, Pears, and Plums. This year the Nuts will be missing, but most other hardy fruits promise us ample compensation.

"Bush fruits—Gooseberries, Currants, and Raspberries, have escaped harm from cold thus far, and will according to present appearances be abundant. Strawberries have borne the winter remarkably well. This remark may appear uncalled for after such a mild winter, but I have lost more plants in a mild wet winter than from any other cause, a large bed containing several hundred plants being totally destroyed in the winter of 1876-7.—EDWARD LUCKHURST."

From a district more westerly still we read:—"Peaches, Nectarines, and Apricots set very thickly, and the trees are looking well. Plums bloomed well—just over; appear setting very freely. Pear bloom good average and setting well. Cherries blooming well and still open. Apple blossom in orchards not yet open, but trees full of bloom buds. Currants blooming freely. Gooseberries well set—a fine crop, some of the most forward as large as robins' eggs. If we have fair weather I anticipate a good fruit year.—JOHN GARLAND, Killerton, Exeter."

From another important fruit-growing district (Herefordshire) we have received the subjoined letter:—"Our fruit prospects here up to the present are very satisfactory with the exception of Pears. Some few varieties have not much blossom upon them, others again have an abundance. Apricots, Peaches, and Nectarines have set well. We are just commencing to thin the Apricots; thousands will have to be taken off. Plums and Cherries have flowered most abundantly, and to all appearance will be a good crop. The Apple blossom is not yet open, but the prospect is good. Gooseberries and Currants look well and promise a good crop. Strawberries are just beginning to open their flowers. Our Apricots, Peaches, and Nectarines are protected with glass copings, with curtains to draw in front of the trees. We have them from three different makers, but Parham's I consider the best.—A. BYE, Hampton Court, Leominster."

From the west and south-west we turn to the east and north-east:—"Notwithstanding the severe frosts at the latter part of March the prospect of fruit is more encouraging than might have been anticipated. We had 13° of frost on the night of the 30th March, and 16° on the 31st.

"Apple blossom is everywhere abundant, and is very bold, and promising in appearance, the foliage being also profuse and very healthy. With favourable weather this most valuable of hardy fruits will be a heavy crop.

"Apricots had the blossom and embryo fruit more or less damaged by the frosts at the end of March; this applies equally to protected as to unprotected trees. The blossoms that escaped injury have set well, and the fruit is swelling fast. The foliage is very abundant—a characteristic of unripened wood. The crop may be an average one if the fruit pass the stoning satisfactorily.

"Cherries are very abundantly furnished with blossom, or rather buds advancing to the flowering state very rapidly, and are very healthy, promising a very full crop.

"Pears are very variable, old standard trees being abundantly furnished with blossom, whilst many of the choicer kinds against walls are sparingly furnished. Upon the whole the prospect of Pears is only moderate. Excepting to a few of the earliest blossom no injury has been done by frost.

"Plums are sheets of bloom, the blossom very strong and healthy. If frost keep away Plums will be an abundant crop.

"Peaches and Nectarines were not injured by the frosts of late March. The blossom, however, were only scant, but the fruit has set well, every blossom apparently having set. The growth is very free, foliage being abundantly produced and so far healthy.

"Gooseberries have not been damaged as was at one time feared; they are masses of fruitfulness. Some complain of damage by frost, the foliage and fruit having a yellow hue, yet the flowers are bold and perfect, and the prospect is generally good.

"Currants both Black and Red promise an abundant crop. Raspberries are very strong, the fruit likely to be fine if not abundant.

"Strawberries are throwing up the trusses very strongly and abundantly, and have an abundance also already of very healthy foliage.

"Upon the whole the prospect of fruit is very assuring, but it remains to be seen what will be the effect upon the crop of the badly ripened wood when stoning or seeding, presuming the blossom to escape injury from frost.—G. ABBEY."

Another correspondent writes from a more southerly point on the east coast:—"Apples promise to be a fair crop, neither the dull and wet summer of last year nor the spring frosts of this having done them any serious amount of injury. Pears will not be a good crop, owing in a great measure to the dull weather of last year, and not to the frost, although some sorts promise fairly, especially Beurré Diel, Beurré d'Amanlis, Bergamotte d'Esperen, and Winter Nelis. Notably barren are Citron des Carmes, Marie Louise, Easter Beurré, and Louise Bonne of Jersey. Plums promise to be a rather extraordinary crop, if amount of blossom stands for anything. Cherries too, I think, will be a fair crop. Peaches outdoors will be next to a failure, as far as can be judged at present, owing partly to the unsatisfactory way the wood ripened last year and the spring frosts, although the failure is more attributable to the former than the latter cause. Apricots will be a better crop than has been the case for the last two years, especially on old trees; on younger trees of rampant growth the wood was not ripened, and fruit is more scarce. Gooseberries will be a fair crop, but Currants will not be so plentiful.—EAST LINCOLN."

The prospects in the north are embodied in the accompanying report from the county of Durham:—"After a full examination of the fruit in this district I find Apricots, Peaches, and Nectarines setting thinly, but are not sufficiently far enough advanced to make sure of which is really set. The prospect is good."

"Apples are looking promising, the following trees being full of flower, and a sight worth seeing at the present time:—Ribston Pippin, Ecklinville, Oslin, Mannington's Pearmain, Scarlet Nonpareil, Large Cockpit, King Apple, Margil, Boston Russet, Claygate Pearmain, Lemon Pippin, Stirling Castle, Reinette du Canada, Ashmead's Kernel, Pearson's Plate, Gravenstein, Dutch Mignonne, Bar's Apple, Pitmaston Nonpareil, Jolly Beggar, Golden Pippin, Duke of Devonshire, Baron Ward, Duchess of Oldenburg, Rymer, Magnum Bonum, Cellini, Dumelow's Seedling, Keswick and Manks Codlins, Red Astrachan, Cockle Pippin, and Wellington."

"Pears thickly in flower are Beurré Easter, Jargonelle, Beurré Incomparable, Comte de Flandre, Hessel, Green Yair, Winter Nelis, Muirfowl's Egg, Beurré Diel, Williams' Bon Chrétien, Marie Louise, Beurré Clairgeau, Beurré de Capiaumont, Vicar of Winkfield, Doyenné du Comice, Soldat d'Esperen, Passe Colmar, Flemish Beauty, Beurré d'Anjou, Beurré Superfin, Comte de Lamy, Beurré Giffard, Matthews' Eliza, Louise Bonne of Jersey, Althorp Crassane, Beurré Magnifique, Prince Albert, and Beurré Langelier."

"Plums and Cherries are covered with bloom, but the fruit is not set. The trees and blossom are full of health, and good results are expected."

"The Gooseberry trees have suffered considerably, and assume a sickly appearance from the early frosts, yet if the late kinds hold good a fair crop may be expected. Other bush fruits are similarly injured. Strawberries are healthy and full of bud, and every signs of a good crop. Cold east winds have prevailed for these last ten days, which are injurious to our fruit crops here, but the weather is gradually becoming milder.—J. HUNTER, *Lambton Castle*."

MIDLAND COUNTIES.—Regarding the prospects for fruit in the midland counties generally the information which we have received is correctly represented in the two subjoined communications.

"Taking a glance over a wide extent of country I arrive at the following estimate:—

"Apples.—The show of blossom, on orchard trees especially, is one of the finest of recent years. The trees are densely covered with bold blossoms, which have expanded and are expanding with great freedom. I never remember seeing the flowers so abundant and yet so fine. No injury as yet has been done to this crop by the frost, and should the genial weather we are now enjoying continue throughout the present month a heavy crop of fruit must result. We often, however, have severe frosts towards the end of the month; indeed I once remember the whole crop was destroyed by frost in June. Pruned trees in gardens, especially those that made luxuriant growth, are not generally so full of blossom, as the wood on such trees was not well matured."

"Pears are very variable. A few trees have blossomed freely,

but still more are barren. The majority, however, have produced about half a crop of blossom and may mature about a quarter of a crop of fruit. Some of the blossoms have been injured by frost; the petals are fresh enough and the flowers fine and apparently healthy, but the petals are the hardest part of the flower, the tenderest being the ovary. Even when the pistil and stamens are uninjured the centre of the ovary, the germ of life, is often blackened, and the fruit is thus really dead and buried in its flowery tomb. Trees that have grown the most vigorously are the most destitute of blossom. We want more naturally grown trees: the crops produced by these are the most certain and weighty."

"Plums.—Unpruned trees have blossomed with great freedom, pruned trees less freely. Many of the blossoms have been destroyed, but, fine weather continuing, a good crop is expected. Victoria is the most productive variety; indeed in the counties of Derby, Notts, Lincoln, and Leicester the aggregate weight of the crop of Victorias will probably equal all the other varieties put together. The trees generally are very free from the aphid."

"Cherries.—This fruit is not grown nearly so largely in this district as Plums, but most of the Cherry trees are sheets of bloom, and, weather permitting, will produce good crops of fruit."

"Peaches, Nectarines, and Apricots.—The blossom on these was not generally profuse. In some gardens the crops have been much injured, while in others they have escaped injury. Probably a moderate crop will be produced in 'the midlands' of those proverbially (without efficient protection) uncertain fruits."

"Small fruits, such as Gooseberries, Currants, Raspberries, and Strawberries, promise to be plentiful."

"In prognosticating a good fruit year in the central district of England I do so on the assumption that we have seen the last of this year's spring frosts, a circumstance that, I regret to say, is by no means certain.—A MIDLAND COUNTIES FRUIT-GROWER."

"Apricots are not much grown in this locality; what few there are had a good show of bloom, but the frosts prevailing at the time killed nearly all. Some trees very much sheltered have a little fruit on."

"Apples.—These are not in bloom yet, but there is a very good show of blossom only waiting for favourable weather to open."

"Pears.—Of these some cordons have set a partial crop. Only a few trees on the walls are blooming well. I may add that we cannot grow winter Pears with any flavour here on our stiff cold clay, and are going to discard them, simply growing Marie Louise, Louise Bonne of Jersey, and Williams' Bon Chrétien."

"Plums.—Of these there is a splendid set of all kinds on the walls. The standards are quite denuded of buds by the bullfinches."

"Peaches.—All are protected by glass, and have good crops. It is no use trying to grow them without glass protection here."

"Cherries.—The Morellos are showing well, but the blossoms are not open yet. The sweet kinds are covered in bloom, and there is every promise of a good crop."

"Currants and Gooseberries.—A fair average crop of both."

"Take it altogether, I believe now with favourable weather we shall have quite an average crop of fruit. The blossoming being late and the weather so dry, the late frosts effected but little injury except to the Apricots.—W. BENNETT, *Rangemore Gardens*."

IRELAND.

"During my experience I have not witnessed a better prospect of fruit in general than the present season exhibits in the south of Ireland; and, if the frosts which are so prevalent about the beginning of May are not unusually severe, I am confident that we may look forward hopefully for an abundant crop of all sorts of fruit in autumn."

"Apples.—Notwithstanding the mild and genial winter and spring I find the Apple unusually slow in putting forth its buds and blossoms; but this, in my opinion, augurs well for the ensuing crop, as the foliage is coming boldly forward with the blossom, and will naturally prove of much value in affording protection to the bloom and infant fruit from any adverse breezes or nipping frosts to which they may yet be subject."

"Pears.—The Pear also has a much better prospect than usual, although such as bloomed early had some sharp easterly breezes to contend against; still I find that the present prospect is exceedingly good, the trees having an abundance of fruit

set and uninjured. At present we have a goodly number of trees in full blossom promising well, and if the present favourable weather continues for about ten days longer we may anticipate a heavy crop in autumn.

"Cherries.—On the Cherry I have never seen such an abundance of bloom, which up to the present has not received the slightest check. If the weather continue to favour us as the past has done our crop of Cherries will be very heavy.

"Plums also have a most flourishing and healthy appearance, but those of early bloom suffered more or less severely, which will prove injurious to the crop; but we hope that those in bloom at present will (from their present appearance) fully compensate for any loss sustained by the earlier-blooming varieties.

"Peaches have set a very fair crop, especially Royal George, which I consider is the best Peach to grow out of doors. Barrington and Noblesse have suffered a little from sharp easterly breezes, which produced blister of foliage, but notwithstanding there is a considerable share of fruit set, which I hope will come to perfection.

"Bush fruits promise abundantly. In the Gooseberry department the bushes are literally loaded, and the fruit has attained the size of a robin's egg, therefore we consider them out of all danger, and especially as an abundance of foliage will afford them any shelter they may now require.

"Currants promise well; they are not quite out of danger yet, but being hardy we look on this crop as certain.

"Raspberries.—From the appearance which the Raspberry wears at present we have reason to hope for an abundant crop, as the bushes are literally covered with unexpanded blossom buds.

"Strawberries appear to be rather backward; they are fully ten days behind what they should be, or rather behind what I have heretofore seen at this period of the year; but their fruiting crowns are unusually strong and plentiful, and though seeming a little backward as to time in other respects promise well.

"I am fully convinced from what I have heard and seen of the prospects of the fruit crop generally in the south and west of Ireland that it is most pleasing and satisfactory.—ANDREW CAMPBELL, *Muckross Gardens*."

We have also received the following from the "Sister Isle":—"The fruit prospects in this district are very promising. Plums and Apricots are all set and swelling, Cherries have a good appearance, Pears all showing well, and the blossoms are strong. Apples have a good appearance, but not in bloom. Small fruit I think will be a good average. Strawberries are throwing up fine strong crowns and looking well. If we get safe through May without frost I believe in this district we shall have an abundant supply of fruit.—JAMES TAYLOR, *Mountstewart, Newtownards*."

"My field of observation is chiefly that under my control. Apples, prospect under the average; very backward. Apricots and Cherries, I cannot find a fruit on the trees. Pears, a fine display of bloom. Should weather keep favourable we anticipate a heavy crop. Plums generally and Damsons have made a tolerable display of bloom, with prospect of an average crop. Peaches and Nectarines few or none, owing to severe frost while in bloom. Bush fruits, Currants, and Gooseberries promise a fair crop. Snails a wonderful crop; they clear nearly all my kitchen-garden produce.—E. KNOWLDEN, *The Gardens, Carton, Maynooth*."

SCOTLAND.

We have been favoured with the following interesting communication from one of the best of Scottish gardeners:—

"We are now enjoying beautiful spring weather, and crops of all kinds are making rapid progress; but we, like all the rest of Great Britain, had a sharp taste of winter at the end of March and beginning of April. On the 29th of March we had 12° of frost, and on the 4th inst. 8 inches of snow made matters look serious for the chances of the fruit crop. The previous four or five weeks were rather mild, and fruit trees were rapidly pushing into flower when the frost set in. All flowers open and exposed to the frost were cut off, but Peaches covered with two or three ply of old herring nets escaped with little injury and promise now to bear a fair crop. Apricots, being in full flower, were rather badly injured and are a thin crop generally; in some gardens none. In dry, warm, airy gardens where protected a good many have pulled through. Few Pears were in flower, but I find that in all the blossom which was near opening the pistil and ovary are killed and

quite black, and the stamens are so much injured that few of them are opening. The flowers are opening perfectly and make a grand display, but of course none of them will set. The latter flowers are not injured by the frost, but they are of a flabby nature and many of them abortive. This I attribute to the gross growth the trees made last autumn and which ripened badly. Many sorts that hardly ever miss here are almost without a flower, notably the Hesse, a favourite market sort that scarcely ever misses.

"Apples look most promising, and have a profuse crop of blossoms upon them. Like everything else they are bursting rapidly into leaf: but it is curious and interesting to note that most of our best bearing sorts, that are hardly ever without a crop, are among the latest in starting into growth. Hawthorn-den, Cellini, Ecklinville, Stirling Castle, Nonesuch, Warner's King, Blenheim Orange, and King of the Pippins have scarcely started a bud when most other sorts are nearly in full leaf. The Codlin tribe, including Lord Suffield, are early starters, but prolific bearers when they get a chance.

"Plums have an abundance of fine healthy blossom now setting freely and promising a heavy crop. Cherries are looking equally well; indeed there has not been such an appearance in this district for a crop of Plums and Cherries for many years past.

"Gooseberries were in full flower and nearly in full leaf when the frost set in; still they have suffered very little injury and promise a good crop. Currants and Raspberries had their foliage nipped by the frost, but have now quite recovered and promise to bear a heavy crop. Strawberries are coming up strong and healthy, and are also likely to be a fine crop.

"On the whole the prospects of a good fruit crop are much more encouraging at the present time than we could have expected after such a wretchedly bad autumn and winter for maturing the wood and blossom, which would have been easily injured by frost previous to the fine and dry weather between the middle of February and the end of March. That dry period, no doubt, was the primary cause of the comparatively small amount of injury done by the late severe frost; and probably the severity of the weather at so recent a date accounts for the freedom from insect pests which the trees still enjoy. The comparatively mild winter and early spring was greatly in favour of all kinds of vegetables, which have been unusually plentiful and good this spring. Under the influence of the present genial weather kitchen-garden crops are growing very fast, and with a continuance of such weather they will be both early and good.

"I have been over a large extent of the country lately—from Carlisle in the south to Aberdeen in the north, and everywhere there is the same fine appearance: trees and bushes in fine health, and the flowers where open simply magnificent. The weather is as good as we can wish it, and good crops of fruit are anticipated."

WALES.

"I have been looking over our trees to ascertain how the fruit crops of 1878 are likely to stand, and upon the whole I think there is reason to be thankful so far. The Apricot trees were in full bloom by the end of February. At that time and during the first half of March the weather was extremely favourable, and the promise of Apricots was enormous, but the severest part of our winter came in the latter half of March and the first week in April; bold winds were more prevalent than frost, and nothing injures vegetation more than cutting east winds. On All-Fools'-day I had quite given up all hopes of having a single Apricot, but now that the fruit is formed and nearly as large as walnuts I see there is a fair sprinkling on most of the trees. Last year we hung nets in front of Apricots when they were in blossom and we had no fruit. This year we left them to Providence, and notwithstanding the severe weather the result is as stated above. When fruit blossoms can be thoroughly protected I think it is a decided advantage, when only partially it is worse than nothing.

"Since the second week in April the weather has been excellent, and Plums on walls and as standards, also Peaches have set well. Cherries are just going out of bloom. Every branch of every kind, especially the Morellos, has been a perfect sheet of white, and if only half the flowers swell into fruit the crop will ultimately be splendid. Many of the Pears are in bloom and a few are past, and all are looking well. Only a few of the earlier Apples are in full bloom. Midseason and late sorts are well covered with buds.

"Gooseberries are loaded with fruit. All kinds of Currants

will soon be in the same state. Raspberries are not forward enough yet to tell what the crop will be, but the shoots are pushing strongly. Strawberries promise well, Black Prince is in full flower. This is an excellent Strawberry for preserving, as it is a certain bearer and always produces an immense crop of highly coloured fruit. Altogether our fruit crops are in a very favourable state at present, and should the weather prove favourable throughout the result will be satisfactory.—J. MUIR."

HOUSE SEWAGE FOR MANURE.

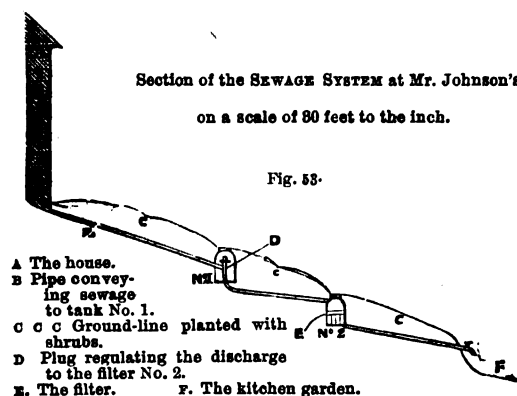

THE best reply we can make to our "Woolwich correspondent" is to reprint the following, which was communicated to us by the late Mr. C. W. Johnson:—

The Collection of the Sewage.—If the house is on a very steep declivity it may be collected in the following mode:—

"I have the advantage of a considerable fall between the house and the kitchen garden, yet that circumstance is not essential to the success of the plan; for even in the case of a perfect level it would only be necessary to add a common iron lifting pump to the second tank; or the object might be accomplished by even one tank only, if furnished with a division. My plan was to test the possibility of filtering the entire sewage of the house through a filter of sand sufficiently fine to remove almost all the mechanically suspended matters of the sewage, so as to render the filtered liquid available as a rich liquid manure, without being offensive to those who had the use of the garden. For this purpose I had two tanks constructed of bricks and mortar and lined with Parker's cement,

Section of the SEWAGE SYSTEM at Mr. Johnson's
on a scale of 80 feet to the inch.

Fig. 58.

of about 5 feet cube each. Into the first, marked No. 1 in the annexed plan, all the sewage of the house is discharged through an iron pipe of $1\frac{1}{2}$ -inch bore. This tank is furnished with an iron pipe of the same diameter which (regulated by a long-handled plug from the top of the tank marked D), discharges the sewage as it is needed from the tank No. 1 into the tank No. 2. This lower tank is also of a cube equal to about 5 feet in diameter. This is furnished with a filter, through which the liquid portion of the sewage finds its way; and is thence drawn off from the bottom of the tank by means of iron pipes of three-quarters of an inch bore to convenient places in the garden. The filter (E) is placed, resting on bricks, about 18 inches from the bottom of the tank. The bottom of the filter is formed of perforated tiles used by malsters for their kiln-floors; on this is laid a layer of gravel about 2 inches thick, on this about 2 inches of coarse sand, and on the top of the sand, to prevent disturbance by the rushing-in of the sewage from the upper tank, another layer of the malster's tiles. Thus constructed, the sewage finds its way through the filter with sufficient rapidity for the copious supply of the kitchen garden. As thus prepared the liquid manure passes through so as to possess but little smell and without leaving any obnoxious appearance on the surface of the ground. I need hardly say that the effect of this liquid is exceedingly powerful; and we have noticed it as remarkably so in the case of some newly planted beds of Asparagus and Rhubarb which have been irrigated with it; and, in fact, there is no doubt of its value for insuring the rapid growth of all kinds of newly planted culinary vegetables. I have so arranged the pipes in my kitchen garden that I can irrigate to any portion of it by merely turning a cock. This plan of filtering seems, in fact, to remove all the objections that can possibly be urged

against the use of the house sewage. And in the case of gardens, both for the amateur and the poor cottager, I feel convinced that, by such a mode as this, many of the difficulties of incessant cropping and little-varied exhausting rotations may be successfully met. The waste of fertilising matter in such sewage is, in fact, so much larger than is commonly supposed—a loss by the ordinary mode of constructing these tanks disguised in every possible way, that I feel assured it only needs the adoption of some such a mode as that which I have described, of rendering its use no longer distasteful to the occupants of the house, to insure its almost universal employment. The amount of sewage is much larger than is commonly understood; and in dry weather, when the demands of the gardener are larger, it is, we find, very easy to increase its bulk, in case of need, by pumping water into the tanks through the ordinary means."—(*Manures for the Many*.)

MARÉCHAL NIEL ROSE.

I CAN truly supplement Mr. Moorman's letter encouraging the growth of this grandest of Roses in conservatories. My Rose was budded on the common Briar and planted-out in the central bed of a cool greenhouse (20 feet long). Last year, its first year of blooming, it bore about thirty flowers. This year, having grown over a greater part of the roof, it produced 480 splendid blooms during March and April. On Easter eve seventy blooms were cut for the church decorations, and that without stripping the tree. My friends tell me that this tree, having bloomed so freely this year, will linger on but never again bloom satisfactorily. I gather from Mr. Moorman that this is not his experience, but perhaps he or some other rosarian can recommend a treatment which may avert such a calamity.

I succeeded in effectually keeping under that pest, green fly, by a liberal use of the syringe. Shortly before the buds were ready to expand the house was well fumigated on two successive nights. I found it far better to hang the tobacco pans from the cross rafters than to place them on the ground; by this means the strength of the tobacco was brought close to the foliage.—J. M. FULLER, Vicarage, Bealey.

ROYAL HORTICULTURAL SOCIETY.

MAY 7TH.

A REALLY splendid and very extensive exhibition was arranged in the conservatory: both sides of the central promenade of the large structure were occupied by admirable collections staged by the chief nurserymen and private gardeners who usually exhibit at these instructive and attractive meetings. The exhibition was in fact quite equal to some that we have seen when large prizes have been offered; indeed, it was in some points superior than where competitive collections have been staged. The plants at a miscellaneous gathering of this nature do not consist primarily of a few large formal specimens which have been trotted out again and again, but are composed of a great number of plants that are either new or rare, or which are specially valuable for decorative purposes. Besides extensive collections of plants there was a small but creditable supply of fruit, and a few good vegetables exhibited.

FRUIT COMMITTEE.—Henry Webb, Esq., Vice-President, in the chair. Mr. G. T. Miles, The Gardens, Wycombe Abbey, sent a dish of each of Elton and Black Tartarian Cherries of very fine quality, to which a cultural commendation was awarded. Mr. Parr, The Gardens, Harrow Weald Park, Stanmore, sent a dish of a large coarse-looking Strawberry, incorrectly named Alice Maud. Mr. Iggulden, gardener to R. B. Wingfield-Baker, Esq., Orsett Hall, Romford, sent a basket of fruit consisting of two bunches of Black Prince and two of Foster's Seedling Grapes and Victory of Bath Melon, to which a letter of thanks was awarded. Mr. R. Gilbert, The Gardens, Burghley, Stamford, sent three bunches of Foster's White Seedling Grape, a dish of each Hathaway's Excelsior and Carter's Green Gage Tomatoes, and Myatt's Prolific and Alpha Potatoes, also a dish of Mushrooms; a cultural commendation was awarded. Three new varieties of Broccoli were submitted for certificates. Mr. Gilbert of Burghley sent one called "The Chairman;" Mr. Ellam of The Gardens, Bodorgan, sent a dwarf white; and Mr. Howard, Priory Gardens, St. Osyth, sent "Model." Neither of them was considered an improvement upon varieties which are already in cultivation. Mr. Gilbert also sent a seedling Cucumber called "Montrose."

Mr. Killick of Langley, Maidstone, exhibited dishes of Dumelew's Seedling, Gooseberry Apple, Kingswood Crab, and Sturmer Pippin in a fine state of preservation. A letter of thanks was awarded. Mr. Gilbert exhibited a dish of Early Beatrice Peach perfectly ripe, to which a cultural commendation was awarded.

Mr. Osman, South Metropolitan District Schools, Sutton, Surrey, sent a dish of Late Rose Potatoes of crop 1877.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. James Veitch & Sons exhibited a very choice collection of new plants, amongst which the following were awarded first-class certificates—*Azalea Madame Charles Van Eckhaute*, semi-double, white, large flowers; a splendid variety. *Azalea Kaiser William*, rosy salmon, very double and free; a valuable variety. *Coleus George Bunyard*, a distinct and remarkable variety of the *Verschaffeltii* type, the centre of the leaf being deep rose veined with purplish magenta. *Rhipidopteris peltata gracillima*, an elegant garden hybrid; a chaste gem among dwarf Ferns. *Adiantum Lawsonianum*, a garden variety, almost as slender as *A. gracillimum*, but with the triangular-shaped pinnae more thinly arranged; and for *Primula acaulis sulphurea*. So many inferior and useless *Primroses* are from time to time exhibited that it is a treat to find something really valuable and useful as this is sure to be. The flowers are $1\frac{1}{2}$ inch in diameter, and the plant is of vigorous habit and flowers with great freedom. It will prove very acceptable for spring decoration. A botanical certificate was awarded to the same firm for the elegant *Dioscorea retusa*.

Mr. William Bull was awarded a first-class certificate for a remarkable plant, *Marica pacifica*, having a beautiful Iris-like flower. It has coriaceous foliage, arched, and the flower stem appears to grow up the interior of the leaf and produce its flowers an inch or two from the summit. The three-fall petals are pure ivory white, and the upper petals reddish brown striped with intense violet blue, with a central blotch of white; it is both curious and beautiful.

Mr. B. S. Williams had first-class certificates for *Coleus Kentish Fire*, leaves serrated and waved, colour bright maroon with purplish crimson veins, very bright; for the distinct and fine Fern *Anemidictyon phillidites tessellata*, and for *Adiantum Lawsonianum* above noticed; it is said to be a sport from *A. cuneatum*, and is very distinct. Mr. Williams also exhibited highly coloured examples of the two bright *Dracenas Frederickii* and *Renardae*.

First-class certificates were also awarded to Mr. Douglas for his fine Alpine *Auricula Silvia*; to Mr. Dean for *Aquilegia alpina cærulea*, a dark and massive flower; to Mr. Elwes for *Iris Leichtlinii* and *Camassia Brownii*; to Rev. H. N. Ellacombe for *Bomaria Caldasii*; and to Mr. James Atkins, Painswick, for *Saxifraga calycifolia*. A botanical certificate was also awarded to Mr. Atkins for *Androsace sarmentosa*.

We can only glance rapidly at the miscellaneous collections in the order in which they were arranged. On entering the building the first was an extensive and imposing group of *Azaleas* from Messrs. Wm. Bollislon & Sons, Tooting. They were low standard plants on stems ranging from 1 to 3 feet high with heads of the same diameter. The plants were excellently bloomed, admirably grown, and were composed of select varieties. Associated with them were Heaths and New Holland plants, the group being backed by a row of Palms and fringed with small plants of Ferns. It was altogether a superior collection.

Adjoining it was a striking group of *Roses* and *Azaleas* arranged by Messrs. Veitch. The *Roses* were in 8 and 10-inch pots, the plants being dwarf and very fine in foliage, each carrying from twelve to twenty remarkably fresh blooms. They included the best varieties, such as *Marie Van Houtte*, *Marquise de Castellane*, *Duchesse de Vallombrosa*, *Louisa Wood*, *Dupuy-Jamain*, *Victor Verdier*, *Madame Lacharme*, *Royal Standard*, &c. It is impossible to speak too highly of such plants as these for decorative purposes. The *Azaleas* also were highly effective, some of the plants being pyramids 4 to 5 feet high and through. The finest plant, and a fine variety, was *Extraneal*, a rich glowing pink. Amongst the smaller plants *Flambeau* was intensely rich; and *Roi des Belles*, one of the best of the double scarlet varieties, and *Marie Van Houtte*, a superior bright flower, were noticeable in this collection. The same firm also exhibited an imposing collection of cut blooms of *Rhododendrons* in fine trusses and splendid varieties; *Azalea mollis* in variety was extremely fine, and *Magnolias*. This collection, arranged at the extreme end of the building, had a commanding appearance and was much admired.

Mr. Wills exhibited a large group arranged in his usual pleasing style, Ferns, Orchids, Lilies, Palms, *Richardias*, &c., being associated in a natural and attractive manner. He also exhibited a collection of *Gloxinias* raised from seed at the Anerley Nursery by Mr. Bause. The plants were excellently grown, and the varieties were of great merit, the flowers being very large and stout and the colours rich and well defined. They produced a very imposing effect, and commanded much attention. One of them, *Beauty of Anerley*, a large crimson flower of great substance, was awarded a first-class certificate.

Messrs. H. Lane & Son, Great Berkhamstead, contributed an extensive collection of *Roses*. The plants were in small pots, and contained remarkably fine blooms. They had, as a front row, small and densely flowered plants of *Azalea mollis*, which were not only intrinsically good but imparted a good finish to the bank of *Roses*.

Messrs. William Paul & Son, Waltham Cross, Herts, exhibited an effective collection of *Roses* in pots, also half a dozen boxes of cut blooms. The blooms both on the plants and in the boxes were very fine.

We now reach the end of the conservatory and find a very attractive group of cut flowers from Mr. Peter Barr. They were composed of *Narcisuses*, *Scillas*, the brilliant *Anemone fulgens*, and other hardy flowers, and produced a most cheerful effect.

The first collection on the opposite side of the building was composed of a highly interesting assortment of bulbous plants exhibited by Mr. H. J. Elwes, Preston House, Cirencester. Tulips were represented in different species, also *Ornithogalums*, *Cypripediums*, *Leucojums*, *Orchis*, *Fritillarias*, *Cyclobotras*, *Watsonia fulgens*, *Polygonatum macrophyllum*, very fine, &c.; and near them Mr. Cannell exhibited a box of cut blooms of the lovely *Salmon Vesuvius Geranium*, also the pure *White Vesuvius*, as well as very fine *Mimuluses*.

The next group on the same side of the building was a large collection of *Azaleas* in 6 and 8-inch pots, arranged by Mr. O. Turner, Slough. The plants were admirably bloomed, and their effect was enhanced by the few elegant Palms that were interspersed amongst them, and the refreshing margin of *Isolepis gracilis*. A few of the more striking of the *Azaleas* were *Bon pour le Commerce*, scarlet semi-double; *Jean Vervaene*, rosy-salmon feathered, white, fine; *Grandis*, cerise, a remarkable flower; *Mons. Thibaut*, scarlet; *Dr. D. Moore*, rosy-pink, double; and *Apollo*, very fine white. Mr. Turner also exhibited a bold and striking single *Petunia Mount Beauty*, colour purplish mauve, and a white *Gloxinia*-like throat.

Messrs. Osborn & Sons, Fulham, staged a fresh collection, in which Palms predominated, interspersed with *Rhododendrons*, *Anthuriums*, &c.

In fine contrast with the above was a contribution of twelve boxes of cut *Roses* from Messrs. Paul & Son, the Old Nurseries, Cheshunt. The blooms were extremely fresh and good in colour, especially *Céline Forestier*, *Duc de Rohan*, *Cheshunt Hybrid*, *La France*, *Annie Laxton*, *Belle Lyonnaise*, *Duke of Edinburgh*, *Madame Denis*, pure white; *Madame Willermoz*, &c.—an excellent collection. Mr. W. Iggulden, gardener to R. B. Wingfield-Baker, Esq., Orsett Hall, Romford, exhibited a basket of blooms of *La France*; both flowers and foliage were alike superior, and they were arranged with much taste. Mr. James Wheble, Bulmershe Court, Reading, exhibited trusses of *Rhododendrons* from a tree upwards of eighty years old. The variety is *Russelliana*, scarlet. They were surrounded with trusses of a white variety, *Snowdon*, from the same exhibitor.

We next arrived at an extensive, varied, and excellent miscellaneous collection from Mr. B. S. Williams. Flowering plants predominated, the most effective being *Franciscea calycina*, *Azaleas indica* vars. and *mollis-Ericas*, &c. The collection also contained small and heavily fruited plants of *Oranges*. *Dracena Bausei* was very striking in this group, as also was *D. Goldiana*.

Adjoining Mr. Williams' group was a remarkable collection of Orchids from Sir Trevor Lawrence, Bart., Burford Lodge, Reading. In the centre of the group a large plant of *Oncidium Marshallianum* spread its golden branches, which drooped over the smaller plants like a fountain of gold. In fine contrast with this plant was the dwarf and equally bright *Oncidium bifolium major*, the plant being on a block and profusely flowered. *Dendrobium thrysiflorum* and *D. Dayanum* were very fine, and *Lælia majalis* with its reticulated lip was in grand condition. *Cattleya Skinneri* was represented by a large plant with highly coloured flowers. *Odontoglossum Cervantesii decorum*, *O. Dawsoni*, *O. scepterum*, *O. Andersonianum*, *O. cirrhosum*, and *O. vexillarium* were all excellently exhibited. The flowers of the last-named grand Orchid were the finest that we have ever seen. They were $4\frac{1}{2}$ inches across measured diagonally. The plant was only in a $3\frac{1}{2}$ -inch pot, and contained two spikes, seven flowers being expanded. The health and vigour of the plant was altogether remarkable. The *Masdevallias*, especially *M. Harryana*, were also very fine, as were *Oncidium papilio* and *Cypripedium caudatum*. It was a grand collection of plants—an exhibition of itself.

Mr. Aldous, florist, Gloucester Road, arranged a group of decorative plants, but they were too much crowded. Mr. R. Parker, Tooting, staged plants of *Scillas*—*S. nutans rosea*, *S. n. violacea*, *S. campanulata maxima rosea* and *S. c. maxima alba*, very fine; also cut blooms of *Irises*. Mr. Green, gardener to Sir G. Macleay, Bart., Pendell Court, Bletchingley, had a botanical commendation for *Ichroma elegans*, a *Solanum*-like plant with drooping lilac-purple flowers; and a cultural commendation for *Houstonia cærulea*, a low-growing North American perennial, growing only an inch high, and covered with a profusion of small blue and yellow flowers, which produced a charming effect. Mr. J. Day, Tottenham High Cross, was awarded a vote of thanks for *Cypripedium Stonei* var. *platytanum*, a striking and beautiful variety. Mr. Brown, Brent Nurseries, Hendon, exhibited a new crimson decorative *Pelargonium*, *F. A. Dickson*; it was very floriferous, and will be useful for market purposes. Mr. J. Mayo, Oxford, staged about a hundred blooms of *Maréchal Niel* *Roses*. Mr. Dean exhibited cut flowers of a few hardy border plants; and last but by no means the least noteworthy was a collection of *Gloxinias*, which contained some splendid varieties from the Society's garden at Chiswick.

Large gold Banksian medals were awarded to Messrs. J. Veitch

and Sons for groups of Roses, Azaleas, and cut blooms of Rhododendrons; and to Sir Trevor Lawrence, Bt., M.P., for his collection of Orchids. Small gold Banksian medals were voted to Mr. J. Wills for groups of Gloxinias and miscellaneous plants, and to Messrs. Rolisson & Sons for a collection of plants. Silver-gilt Banksian medals were awarded to Messrs. H. Lane & Son for groups of Roses and Azaleas, and to Mr. B. S. Williams for a group of plants. Silver Banksian medals were voted to Messrs. Paul and Son for cut blooms of Roses, and to Mr. J. Aldous and Messrs. Osborn & Sons for collections of plants. Silver Flora medals were awarded to Messrs. W. Paul & Son for Roses in pots and cut blooms, and to Mr. Turner for Azaleas and Palms; and bronze Banksians to C. Winn, Esq., for *Odontoglossum cirrhozum*; and to Messrs. Mayo & Son for cut blooms of *Maréchal Niel* Roses.

Votes of thanks were awarded to Mr. B. Parker for a group of herbaceous plants, to Mr. W. Iggulden for a basket of Roses, to Mr. J. H. Goodacre for flowering sprays of *Stephanotis* and *Bougainvilleas*, and to J. J. Wheble, Esq., for cut blooms of *Rhododendrons*.

NOTES AND GLEANINGS.

WE are pleased to learn that His Majesty the KING OF THE BELGIANS has been elected an Honorary Member of the Royal Horticultural Society. His Majesty is well known as an ardent patron of horticulture, and has done and is doing much to promote the extension of that industry both in Belgium and England. His Majesty has graciously accepted the honour tendered to him by the Council of the Society.

— AT the General Meeting of the ROYAL HORTICULTURAL SOCIETY held on the 7th inst. the following candidates were duly elected Fellows of the Society—viz., Thomas Benskin, Mrs. Bolton, Mrs. Buchanan, J. Scarlett Campbell, David Carnegie, Lady Emily Cavendish, Admiral Sir James Drummond, Lady Augustus FitzClarence, Captain Thomas Gardner, Charles Clayton Glyn, William Grogan, William Hurst, R. R. Hyatt, Major Charles Keith-Falconer, Hon. Mrs. Locke King, John Jekyll Kingsford, Robert A. Laing, George Murray Lang, Major Lawrie, James Ebenezer Saunders, F.R.S., Mrs. Arthur Tower, Lady Turing, Florence Lady Westbury, Charles K. Wild, Arthur J. Wright, &c. Miss Desvœux, William Beddoe, Miss Kate Jurgensen, Henry Armstrong, were admitted Guinea Members.

— ONE of the richest and most satisfactory displays of *HERBACEOUS CALCEOLARIAS* that has come under our notice is in the conservatory of R. Hudson, Esq., at Clapham Common. Mr. Rapley, the gardener, has grown about three hundred plants in a manner that places him high on the list of successful cultivators. It is not the large size of the plants that renders them noticeable so much as the exuberance and cleanliness of their foliage, and the quality, freshness, and brightness of the flowers. Many of the plants are in 8-inch pots, and these are quite worthy of being arranged at any public exhibition. They are not, however, more noteworthy than are the plants in 5 and 4-inch pots. It is only by judging a plant in conjunction with the size of the pot it is grown in that the true estimate of its merits can be determined. Judging the smaller plants by this test we can assert that we have never seen plants to surpass Mr. Hudson's. They are altogether admirable, and their owner may with commendable pride show them to the most critical of his many visitors. They are home-decorative plants of the first order of excellence, and are giving a rich reward for the care that has been bestowed on their culture. It is worthy of mention that not one plant out of the entire number grown has "gone off," and that there is not one variety unworthy of a place in the conservatory. The seed was saved from selected flowers by the grower of the plants, and was sown in July, and the plants were grown on generously without check from any cause. That is the secret of their excellence—steady onward growth which can only be secured by unremitting attention. They are grown in very strong soil and are potted firmly. The plants are correspondingly strong, yet dwarf—so much so that sticks are not needed to support them, but only to enable the branches being tied out so as to afford room for the expanding flowers. Although the side shoots are numerous and the heads are level and symmetrical, yet the leading shoots have never been pinched nor stopped; the plants have branched naturally, as they will do under good cultivation, and the advice that is not infrequently given to "stop the shoots in order to secure bushy and sturdy plants" may be regarded as obsolete, for it is impossible that plants more dwarf, bushy, and sturdy can be grown than the unstopped specimens referred to. The only stimulant employed to sustain the vigour of the plants is clear soot water, and the rule of applying it is the safe one—weak and often

— MR. WILLS, who is the only English exhibitor of plants at the PARIS EXHIBITION, besides having furnished in an artistic manner a conservatory erected by Messrs. James Boyd and Sons of Paisley, is also, we learn, competing with French exhibitors in several classes, including those for new plants. His Royal Highness the Prince of Wales, accompanied by H.R.H. the Princess of Wales and their Royal Highnesses the Crown Prince and Princess of Denmark, paid a special visit to the conservatory referred to on the 4th inst., and were received by Mr. Wills and Mr. James Boyd, who had the honour of explaining the construction of the building and the arrangement of its interior to their Royal visitors. Mr. Wills and Mr. Boyd were very highly complimented on the success of their undertaking. Mr. Wills has employed some of his choicest plants in the arrangement of the house, and has avoided all staging and vases in order to show the natural style of artistically arranging conservatories and winter gardens. Her Royal Highness the Princess of Wales, charmed with the beauty of the arrangement, requested Mr. Wills to carry out a similar work in the gardens of Marlborough House. Mr. Wills had the honour of presenting bouquets of Roses to the Royal ladies on the occasion of their visit. On leaving the conservatory H.R.H. the Prince of Wales shook hands with Mr. Wills, and thanked him for the pleasure the conservatory and its contents had afforded him. Many English manufacturers of horticultural implements are represented at the Exhibition, and their products are, we are informed, attracting much attention, and are securing the high approval of visitors who are interested in this important department. The Prince has carefully inspected the several exhibits, and has gracefully acknowledged, as President of the British section, the enterprise of the several exhibitors and the excellence of their work. The first purchase made by the Prince at the Exhibition was of one of Barnard, Bishop, and Barnard's slow combustion stoves.

— THE following is the arrangement of Judges for the GREAT SHOW AT PRESTON, which opens on July 10th:—Stove and greenhouse plants, Ericas, &c., Messrs. Baines and Stevens. Orchids, Ferns, and new plants, Messrs. Dominy and Smith, Kew. Crotons, Dracenas, Mr. Bull's cups, &c., Messrs. Parker and Moore. Pelargoniums, Fuchsias, Begonias, &c., Messrs. Fraser, and Harrison, Knowsley. Roses, Messrs. Peach and John Lane. Groups of plants, miscellaneous, bouquets, Conifers, &c., Messrs. Findlay, Wills, and McNab. Fruits (Society's prizes), Messrs. Miles and Smith. Fruits (Messrs. Veitch's prizes), Messrs. Thomson, Drumlanrig; Judd, Warwick Castle; Clarke, Studley Royal; and Speed, Chatsworth. Vegetables (Society's prizes), Messrs. Bartram, Sefton Park; and M. Saul. Vegetables (Messrs. Carter and Suttons' prizes), Messrs. Douglas and Penny. Implements, &c., Messrs. Hibberd, and Ingram, Belvoir. Judges of cottagers' produce to be appointed by the Preston Committee.

— WE regret to learn that much DAMAGE is being done to the FRUIT TREES IN KENT by the presence in great numbers of a small weevil, *Otierynchus picipes*. The weevils infest the trees in thousands and devour both blossom and young leaves, and also eat the dormant buds and bark. The same pest has destroyed some Rose trees in Mr. Druce's garden at Woodford. An useful hint has been communicated to us by Mr. Druce, who has been endeavouring to prevent the weevils ascending the stems of his standard Rose trees. He found that smearing the stems with a ring of birdlime completely arrested the progress of the weevils. The weevils when not feeding conceal themselves in the earth. Applications of gas lime and moderately strong solutions of ammonia to the soil are recommended as means of checking the increase of the destructive pest. It is probable that a weak solution of paraffin and water would have the same effect. It would be advisable also to apply paraffin very much diluted to a portion of the stems and even foliage of the trees with a view of ascertaining if they cannot be rendered distasteful to the insects, while the solution is not sufficiently strong to injure the trees.

— MESSRS. FOLLOWS & BATE, Dutton Street Works, Manchester, have introduced an ingenious contrivance for fastening Vines and climbing plants to the wall or paling against which they are to be trained.

— WE learn that H.R.H. the Prince of Wales, when inspecting the English exhibits at the PARIS INTERNATIONAL EXHIBITION, was much impressed with the magnitude and general excellence of the stands of the eminent firms of Sutton and Sons, Reading; Carter & Co., High Holborn; and E. Webb

and Sons, Stourbridge. The collections of seeds, roots, grasses, &c., arranged by the respective firms will represent the extent and high character of the British seed trade. His Royal Highness expressed his congratulations to the exhibitors on the superiority of their stands, and accepted catalogues of their seeds.

— THE MEMBERS OF THE BROCKHAM ROSE ASSOCIATION are this year to hold their Show on June 27th in the grounds of Holmwood Park by invitation of Mr. Gough Nichols. The membership of this Society is restricted to sixty, to be confined for the future more especially to West Surrey. The Judges who have undertaken the office for 1878 are "D. Deal," the well-known Hon. Secretary of the National Rose Society; W. W. Saunders, Esq., F.R.S.; and Mr. George Paul of Messrs. Paul & Son, Cheshunt. The Local Secretaries are the Rev. Alan Cheales and Charles Mortimer, Esq. The Hon. Treasurer is Capt. E. W. Lang, R.N., under whose able management the Society shows a balance of £19 1s. 6d.

— WE are pleased to observe that the SHROPSHIRE HORTICULTURAL SOCIETY is in a flourishing state financially. According to the balance sheet the expenditure last year was £716 5s. 10d., while the income, including a balance from 1876 of £469 1s. 1d., was £1444 10s. 11d. The balance in hand at the commencement of the present season, amounted to £728 5s. 1d., or £12 0s. 1d. in excess of the whole of last year's expenditure. It is seldom that we have the pleasure of noting such satisfactory financial results in connection with horticultural societies. Prizes to the amount of £275 are offered at the next exhibition, to be held on August 14th and 15th.

— BY the aid of correspondents situated in the various districts of England—also in Ireland, Scotland, and Wales—we are enabled to submit the most reliable estimates attainable as to the FRUIT PROSPECTS OF THE PRESENT YEAR. The accounts, as may be expected, vary somewhat in the different localities, but the most important crop of all—Apples—is, weather permitting, expected to be very large in almost all districts. Pears are very variable, but in the aggregate the yield can only be regarded as a poor one. Plums have sustained injury by the frosts of March and April, yet fairly good crops are expected. Cherries promise to yield well. Peaches, Nectarines, and Apricots vary extremely; in some districts the trees are barren, in others they are laden with fruit. The yield on the whole will probably be moderately good. Gooseberries and Currants promise to produce good but not heavy crops, and Raspberries and Strawberries have an excellent show of blossom. The foliage of the trees is expanding freely, and will afford valuable protection to the fruit against any frosts that may yet occur, and the trees are singularly free from insects.

— WE have received the first schedule of the PUTNEY, FULHAM, AND WANDSWORTH CHRYSANTHEMUM SOCIETY. The Society has been established by the gentry and gardeners of the district with the object of stimulating the culture of flowers and fruits. Baron Pollock is President of the Society, which has also the advantage of an influential body of Vice-Presidents and a practical Committee. The show is to be held on November 12th. Upwards of forty prizes are offered for Chrysanthemums, and classes are also provided for stove and greenhouse plants and fruit. Special prizes are further offered by F. D. Galpin, Esq., and by Mr. Stevens of St. John's Nursery, and Mr. Moore of the Richmond Nursery, Putney. The Society appeals for support to all lovers of horticulture in the district, and we shall be glad to hear that the appeal has been well responded to. Mr. J. Moore, Upper Richmond Road, Putney, is the Secretary of the new Society.

— AT the READING HORTICULTURAL SOCIETY'S SHOW, which is announced to be held on May 23rd, we are informed that besides the prizes offered by the Society, a Veitch memorial medal and a prize of £5 will be offered for three stove and greenhouse plants, Orchids excluded.

— WE recently recorded that fifty thousand TULIPS were flowering in the nursery of Messrs. James Carter & Co. at Perry Hill, Sydenham. We have subsequently had a glance at the gorgeous beds, for gorgeous they were, and indeed are. Such a brilliant mass of colour is seldom to be seen, in England at least, as the display in question. It is difficult to determine which are the more beautiful varieties, as beauty is a relative term and is solely governed by individual taste; but especially glowing are such useful sorts as Vermillion Brilliant, Keyzers Kroon, Duchesse de Parma, Gloria Solis, and Artus. Of more delicate tints are Rose Gris de Lin, a

charming variety, and Royal Standard, an attractively striped flower; and of the self colours the white and yellow Pottebakkers are wonderfully fine. Murillo and La Candeur are fine double white flowers. Only a combination of favourable conditions, such as good bulbs, good soil, and genial weather during the blooming season, could have produced a display so eminently satisfactory as the great and glowing exhibition that the firm has provided.

— WE are requested to state for the information of amateur growers and exhibitors of Roses in pots that Mr. Charles Turner, Mr. George Paul, and Messrs. Veitch & Sons have decided not to exhibit in the open class for six Roses in pots at the Royal Botanic Society's Show on May 22nd; thus, by the consideration of the great exhibitors named, the "open" class referred to practically becomes an amateurs' class with prizes amounting to £6, £4, and £2, for we cannot suppose that any other trade growers of celebrity will oppose any amateur exhibitors who may compete, and who have no class specially provided for them by the Society.

AURICULA SHOWING.

YOUR correspondent "EMBRYO" has hit a blot in the schedule of the Show at the Crystal Palace, and one which, owing to the unfortunate illness of the Secretary at the time of preparing it, could not be remedied. I had proposed that, seeing there were several who wished to commence growing, and perhaps showing, Auriculas (for I had started two friends myself with small collections), that classes should be instituted for them in the same way as in the National Rose Society—viz., that while if possible still retaining the classes already in the schedule, there should be added classes for four and two Auriculas for exhibitors not competing in the previous classes. I should much prefer this to "EMBRYO's" plan of mixing-up Auriculas and Alpines. Anybody can grow and bloom the latter, but what we want to see is the Auricula taking its place about London as it used to do "when I was young," and instead of two or three growers competing having ten or twenty, and this arrangement would give such beginners a chance. The plan met with the approval of one or two of the members of the Committee, and if all goes well I fondly hope may be adopted another year. As there may be persons good-natured enough to imagine I write with an eye to business, let me say I should never consider myself a small grower however my collection may have been diminished.—D., Deal.

KNIGHT'S PROTECTING BROCCOLI.

THIS Broccoli is just now in fine condition with us. We have grown about a dozen leading sorts during the winter, but not one of them has equalled this. The seed was sown about the second week in May last year. When the plants were transferred to the main quarters they were planted only 18 inches apart each way. They have grown about the same in height, and the heads average 7 inches in diameter. At this size they are in prime condition, and many of them are perfectly good when about as large again. Five or six hundred Broccoli plants growing 18 inches apart and bearing firm white heads of these dimensions are not to be despised, and I should like to know how much finer anybody would have expected the heads to have been had the plants been growing as wide again apart? I shall save some of the best of the plants for seed, as, excepting Veitch's Autumn Protecting, I have not seen a Broccoli to equal it for a very long time. Meanwhile let me advise those who want Broccoli at this time next year to lose no time in sowing a little seed of the true Knight's Protecting, and I am sure they will always try to have it afterwards.—A KITCHEN GARDENER.

VEGETABLE CULTURE.

CHAP. XVII.—KIDNEY BEANS.

BEING a native of India the Kidney Bean is one of the most tender vegetables in our gardens. Its season in the open air is rather short, but it submits to forcing better than any other vegetable, and in this way it may be had very early in spring and late in autumn without much trouble; but as the mode of outdoor culture is much more general our first attention will be given to it.

As everyone knows, there are two kinds of Kidney Beans—the tall growers, or Scarlet Runners as they are called, and the dwarfs or so-called French Beans. Although many consider

the dwarf kinds the most tender and best to eat, the runners are equally good when well grown, and about the whole of them it may be said that no greater delicacy can be had in the way of vegetables than a dish of tender well-grown Kidney Beans; and they have one great claim on poor people that must be overlooked, or Kidney Beans would be more grown in cottage gardens than we find them. The claim referred to is their palatableness without any expensive accompaniment, as no sauce nor gravy is necessary to make them toothsome. As to their cultivation, that is simple enough. A rich open soil not less than a foot in depth suits them admirably. We never make any great preparation for our Kidney Bean crop, especially for the dwarf-growing kinds, and we have never failed with them in any kind of soil; but when a really superior row of runners is wanted and the soil is poor a trench should be taken out as for Celery and have a large quantity of manure dug into the bottom of it, sowing the seed 3 inches deep and covering it carefully over as the trench is filled in.

The last week in April or the first week in May is early enough to sow Kidney Beans in most localities. The young growths will not stand the slightest frost, therefore the leaves should never be aboveground until all chance of frost is past. Of course those who are inclined to put in a chance crop earlier may do so. We often do this as we did this spring, when seed of the Canadian Wonder was sown at the end of March, and the plants were showing themselves in the row before the end of April. Luckily there has been no frost, or we should have had to sow again. The dwarf-growing sorts may be sown in rows 18 inches or 2 feet apart. As a single row of moderate length will produce a great quantity of runner Beans; and as nothing is better than these tall-growing Beans for affording shelter to tender crops, or a screen to hide unsightly objects, it is in positions of this kind that they should be grown. The seed of runners may be sown 3 inches apart, dwarfs 2 inches; or the drills may be taken out the width of a spade and the seed be spread thinly over the whole width. As soon as the young plants are 4 inches high a little soil should be drawn to their stems with a hoe. Few of the dwarfs require stakes, but stakes should be put to the runners as soon as the first-formed rough leaves are formed. The stakes may be from 3 to 7 feet high. They should not be allowed to exceed the latter height. The pods should all be gathered immediately they become ready, as leaving them until they are too old to use soon weakens the pod-producing power of the plants. The same remarks apply to dwarfs. From the beginning of May seed of dwarfs for succession should be sown every three weeks until the beginning of August. In fine autumns this last sowing often proves very useful. The tall sorts continue bearing for a much longer time than any others. Runners coming into fruit in June will frequently bear abundantly quite up to the time of frost if the pods are gathered before they become too old, and a few waterings of liquid manure be given in August and September. Where there is a spare frame or two empty in August it is a good plan to sow a few rows in them of the dwarf sorts, and when frost occurs to place the lights over them. By this means the gathering may often be prolonged three weeks or a month longer than out of doors. They should have a firm rich soil in which to grow in frames, and they should be planted the same distance as out of doors. Bending sticks over the rows and covering them over with mats will often give a few dishes later than when uncovered.

Amongst dwarf sorts for general cultivation Canadian Wonder is very far in advance of all others. It grows about 2 feet high. The pods average a foot in length and their numbers are prodigious. Newington Wonder, Fulmer's Forcing and Osborn's Forcing are the next best sorts. The two latter are unsurpassed for forcing. Notes on forcing may, however, be deferred until a more seasonable time.—A KITCHEN GARDENER.

GREENHOUSE ROSES.

THE description "M. M." has given of his splendid Maréchal Niel Rose tree induces me to say a word about Lamarque, Eugène Appert, and Céline Forestier, which are flowering profusely in a cool vinery here, along with Alba rosea and Bessie Johnson. All of those Roses have been a perfect picture for some time. They are planted out in a bed in the middle of the house with a walk all round it, and trained over bent arches made of iron rods and on the rafters as well, where I have removed some of the Vines. Lamarque especially has grown to a great size, and is at this moment covered with its

beautiful white buds and flowers, against which quantities of the large bright pink blossoms of Eugène Appert look lovely. The buds of Lamarque are perfect for buttonholes. Céline Forestier, too, grows well and is flowering, its blooms being great favourites with ladies for their dresses. Alba rosea flowers well, but is not a quick grower like the others; and Bessie Johnson, with its delicate pink flowers, is as deliciously sweet-scented as the old-fashioned Attar Rose. We have been cutting from these plants for the last three months, and they are still a mass of flowers and well repay the trouble that has been spent upon them. Underneath them is a kind of spring garden, Rhododendrons, Azaleas, Lilacs, bulbs, &c., looking very gay at present. On the back wall I have young plants of Maréchal Niel and Gloire de Dijon which have already produced some flowers, and I hope by next year the former may equal "M. M.'s" large plant, as it has started to grow and is in fine health.

Later on these arches and almost the whole house will be covered by the beautiful hanging flowers of Tacsonia Van-Volxemii and the pale blue Maurandya; and in the next house I have a plant in a 12-inch pot of Tropæolum pentaphyllum which has grown along wires in all directions, and its gracefully hanging shoots covered with its curious flowers form a very pretty object. I have brought a shoot of Lamarque into the next house by removing a pane of glass, and intend trying it on the back wall, and will write you the result, as I am a constant reader of your Journal. All my Roses are on their own roots.—H. T. KILLNER, *Gardener, Middleton Hall, Llanarthney, Carmarthen.*

WORMESLEY GRANGE.

THE small parish of Wormesley with its richly wooded hills and picturesque valleys forms one of the most secluded districts of Herefordshire. At the last census in 1871 there were only eighteen dwelling houses with eighty-seven inhabitants, and except at one spot it is difficult to see any two of the houses at the same time. Wormesley Grange is the chief house in the parish, and it is celebrated as the birthplace of Richard Payne Knight and Thomas Andrew Knight, *par nobile fratrum*, the one as distinguished for his literary genius and taste as the other was for his scientific horticulture. Richard Payne Knight was M.P. for Leominster and Ludlow, author of the long didactic poem "The Landscape," and the munificent donor of ancient bronzes, coins, and other articles of vertu to the British Museum; and Thomas Andrew Knight, as has been seen in the sketch of his life in a former number, was the President of the Horticultural Society of London for many years, and he may be called the founder of horticultural science in Great Britain.

Wormesley is mentioned in Domesday Book as one of the possessions held by Roger de Lacy of the King. It is, however, chiefly known in history from the foundation of a Priory of Augustine Canons of the Order of St. Victor in the parish. This Priory is believed to have been established (Dugdale's "Monasticon") as early as the time of King John or the beginning of Henry III., by Richard Talbot of Painswick. It was largely endowed by his successor, Gilbert Talbot, Lord of Credenhill, who gave to the Priory lands in Wormesley, Eardisley, King's Pyon, Weobley, and Lyonshall. It was dedicated to St. Mary and St. Leonard de Pyona. The charters granted to this Priory were very numerous. In the twenty-sixth year of Henry VIII. the total value of its revenues amounted to £89 3s. 9d. per annum, the nett income to £73 10s. 2d. George Earl of Shrewsbury, the descendant of the Talbots, in his letter to John Scudamore, surveyor of monastic property at the dissolution, prays that "the poore house of Wormesley, which is of my foundation (wherein) many of myne ancestors do lye, and the moost parte of the furst of the poore name that I am comyn of" might be spared.—(*Camden Soc. Publ. vol. xxvi.*)

The other chief benefactors to Wormesley Priory were Sir Walter Mass, Edmund Earl of Lancaster, Roger Mortimer, Adam Lucas, John de Oldcastle, John Miners, Roger Pychard, William de Baskerville, Robert de Croft, and William de Capeson. There is a register of Wormesley Priory in the Harleian MSS. in the British Museum, No. 3686, in folio, and some proceedings relating to this property were among the records of the Augmentation Office.

"The Mansions and Manors of Herefordshire," by the Rev. C. J. Robinson, thus traces down its history. After the dissolution the site of the Priory with the appurtenances in Wormes-

ley, together with the rectory and advowson, were granted by Henry VIII. in 1547 to Sir Edward Fiennes, Lord Clinton. From his heirs they passed to Thomas Baskerville, and reverting to the Crown, were given by Queen Elizabeth in 1602 to Silvanus Scory and his heirs, the son of John Scory, Bishop of Hereford, 1559-85.—(*Blount's MS.*) Shortly afterwards they were in possession of Walter Vernon of the Inner Temple, who sold them in 1629 to William Crowther, citizen and haberdasher of London, sometime M.P. for Weobley, and founder of the grammar school in that borough. He was succeeded in 1653

by his nephew, John Crowther, whose widow left Wormesley in 1716 to her cousin, Thomas White of the Inner Temple. He died in 1742, and in 1747 the estate was sold to the Rev. Thomas Knight, who took up his abode at the Grange House, and whose two gifted sons, as we have already said, were born there. The present owner is A. R. Boughton Knight, Esq., of Downton Castle.

The foundation of the old Priory may still be indistinctly seen in the grass of a meadow near the Grange House. Some remains were standing in 1718, but they retained little of their

Fig. 54.—WORMESLEY GRANGE.

monastic character, as shown by a sketch preserved among the Phillipp's MS., except in the stone-mullioned windows and the lofty archway which formed the chief entrance of the house. The only remains existing at this time are scattered stones more or less richly carved, which are preserved as relics or built into a neighbouring wall.

The Grange House was rebuilt by one of the Whites, and was improved and afterwards occupied by the Rev. Thomas Knight from his marriage until his death in 1764. The tombs of himself and his sons—massive monuments in granite—form the chief objects in the little churchyard of Wormesley. There are no traces there of any monuments to the Talbot family, the Gages, or the Baskervilles, though written records say they should be there.

The present use to which Wormesley Grange is now applied

is that of an ordinary farmhouse. The pilgrim of science who travels here in search of traces of Mr. Knight's life-long labours will be disappointed, for though the old orchards which he planted are still in existence, there are no records of any kind connected with them, and even the traditionary evidence of what they formerly were is all but extinct. We naturally looked for the original trees of some of the fruits Mr. Knight succeeded in raising, but none were to be found. The orchards are much decayed which he planted, and the present occupier is ignorant even of the names of the kinds which constitute them. From what we saw we think that the trees are merely seedlings which have been planted out to prove their merit; but merit there is none, for though our visit was made in autumn when the fruit was ripe, there was none that could be considered worthy of being named. For the historical portion

of this paper we are indebted to the courtesy of our friend Dr. Henry Bull of Hereford.

THE NATIONAL SOCIETY'S AURICULA SHOW AT MANCHESTER.

THE first question that would be put to me by Auricula growers and lovers, knowing that I had seen both the northern and southern Shows, is, Which do you think the best? And strange to say my answer would have to be an undecided one, or rather it would be governed from the standpoint from which they were viewed. In extent the southern one, although with fewer exhibitors, was vastly in excess. The classes for fifty and twelve have no place in the northern Show, and I think it would tend greatly to a better appreciation of the flower if the former of these were done away with in the south. To outsiders it is most misleading. The amount of the prizes and the number of the plants leads the uninitiated to believe it to be the best and to contain the finest flowers, whereas in effect, while some good flowers are shown, there are a vast number of inferior and middling sorts; yet, if we turn to the reports of the daily papers, this class is evidently regarded as containing the *crème de la crème* of the Exhibition. If, on the other hand, the quality of the two Shows be inquired after I would unhesitatingly give it to the northern Show. There was a freshness and brightness about many of the plants—indeed the majority—which were in vain sought for at the Crystal Palace. The fact was that the flowers of the southern exhibitors were past their best. The date was sufficiently late, and the steaming weather of the week preceding the Exhibition had been too much for them; while I for one cannot believe that Auriculas opened in 60° of heat, and brought up there a couple of hundred miles, and two or three days out of their pots, can look as fresh or as bright as those grown in the old-fashioned way without heat and shown close at home. Independently of these considerations the blooms were younger and consequently brighter than those shown in the south.

It happens that we are sometimes obliged to eat the leek, at least unless one is so obstinately pigheaded as never to acknowledge a mistake. Only in last week's Journal I said that I should never break the tenth commandment in connection with Prince of Greens; but Mr. Wilson of Halifax has made me eat the leek, for he exhibited it in such condition that it was entirely a different flower to any I have seen of it before. It has indeed one grand defect—the watery tube, but the green is so fine and the paste so solid that one can put up with this; and we have a right to echo Mr. Horner's words when he said that all Auricula growers were much obliged to Mr. Wilson for showing what can be done with it. It is no slight tribute, too, to the success of the late Mr. Traill that the premier prizes in the green-edge class and the premier green edge in the Show were awarded to two of his flowers, Anna and Prince of Greens. Alexander Meiklejohn was also shown in better condition than I have yet seen it by Mr. Woodhead of Halifax, and occupied the position of premier grey edge in the Show, but then neither George Lightbody nor Lancashire Hero were up to the mark this year. In white edges John Simonite will, I imagine, take one of the highest places in a limited class. George Levick was only shown in one instance and not in good condition, and there were no other new flowers of any mark exhibited. Mr. Booth's fine white was past. The northerners repudiate, and I think justly, the southern notion of crutches for their flowers, for all who have ever written on the Auricula have given as one of its characteristics a strong stem that will support the truss; but I am sorry that they still think that three pipes form a truss.

The highest class was for six, and some of the collections exhibited in it were of great excellence. The first prize was awarded to Mr. Ben Simonite for the following—Seedling, George Lightbody, Mrs. Douglas, Lovely Ann, Alexander Meiklejohn, and Talisman; the last was exhibited also at the Crystal Palace, and is a bright green-edged flower. The second to Mr. H. Wilson of Halifax for Alexander Meiklejohn, Countess of Wilton, Leigh's Colonel Taylor, Traill's Prince of Greens, Heap's Smiling Beauty, and Pohlman's Garibaldi; these were all fresh well-bloomed plants, and were a great credit to the grower. The third to Miss Stewart of York for Ann Smith, Lightbody's Lord Clyde, Alderman Wisbey (coarse), Lovely Ann, George Lightbody, and Lancashire Hero. The fourth to Mr. Pohlman for Smiling Beauty, a very lovely example of this fine flower; Blackbird, Colonel Taylor, very beautiful; Ne Plus Ultra, George Lightbody, and Complete; and the fifth to C. Royds, Esq. In Class B, for four Auriculas, one of each class. Mr. Simonite was again first with Talisman, Frank Simonite, George Lightbody, and Duke of Argyll. Mr. Wilson second with Smiling Beauty, Page's Champion, a good example of this fine old flower; George Lightbody, and Richard Kay. Mr. Woodhead was third with Alexander Meiklejohn very good, Pizarro, Ashworth's Regular, and a seedling; and C. Royds, Esq., fourth with Traill's Mayflower, Ellen Lancaster, Litton's Imperator, and Smiling Beauty. In Class C, for two Auriculas, Mr. Royds was first with John Waterston and Blackbird, Miss

Stewart second with Robert Traill and Smith's Lycurgus, Mr. B. Simonite third with John Simonite and George Lightbody, and Mr. T. Mellor fourth with Blackbird and Alexander Meiklejohn. The class-showing brought out some fine flowers, a premier prize and eight others being awarded in each of the four classes. In green edges the premier prize was awarded to Mr. H. Wilson of Halifax for Traill's Anna, who thus carries off double honours in green edges. He was also first with Prince of Greens; Mr. Taylor second with Lancashire Hero, a pure green edge; Mr. H. Wilson third with Colonel Taylor; Mr. Wilson fourth with Page's Champion; Mr. Simonite fifth with a seedling and sixth with another seedling; Mr. Royds seventh with a seedling, and Mr. Wilson eighth with Highland Laddie. In the class for single grey edges Mr. Woodhead took the premier prize with Alexander Meiklejohn well-bloomed and fine; Mr. Booth first with Richard Headly, Mr. Woodhead second with John Waterston, Mr. Booth third with George Lightbody, Mr. Taylor fourth with Lancashire Hero, Mr. Wilson fifth with George Levick, Mr. Simonite sixth with Samuel Barlow a seedling, Mr. Booth seventh with Queen Victoria, and Mr. Simonite eighth with Conqueror of Europe. In single white edges Mr. Taylor took the premier prize with a good plant of Smiling Beauty. Mr. Wilson was first with Regular, Mr. Partington second with Kenyon's Ringleader, Mr. Simonite third with Traill's Beauty and fourth with Frank Simonite, Mr. Booth fifth with Traill's White Rival, Miss Stewart sixth with Ann Smith, Mr. Mellor seventh with Maggie Lauder, and Miss Stewart eighth with Richard Headly. In selfs Mr. Royds took the premier prize with Ellen Lancaster and first with the same, a fine smooth self; Mr. Bateman second with Blackbird; Mr. Wilson third with C. J. Perry, fourth with Garibaldi, and fifth with Netherwood's Othello; Mr. Royds sixth with Mrs. Smith; Mr. Pohlman seventh with Lord of Lorne; and Mr. Wilson eighth with Meteor Flag.

In the special prizes the prize for the best green edge in the Exhibition was awarded to Mr. H. Wilson for a beautifully bloomed plant of Traill's Anna, and for the best grey edge to Mr. Woodhead for Alexander Meiklejohn, and another for the best Lancashire Hero to Miss Stewart.

I have already given the names of the winners in the Alpine class; and I should add that, independently of the Auriculas, there was a very beautiful show of other flowers. Mr. Broome of Didsbury, Mr. Yates of Sale, Messrs. Standish & Co. of Ascot, and others exhibited some very charming groups of Orchids and other stove and greenhouse plants; while Messrs. Paul & Son showed a very beautiful collection of Roses, cut blooms, and a few in pots. The cut blooms comprised Edouard Morren, Maréchal Niel, Cheshunt Hybrid, Gloire de Dijon, Alfred Colomb, Souvenir d'Elise, Madame Victor Verdier, Marquise de Castellane, Catherine Mermet, Marchioness of Exeter, Camille Bernardin, La France, Madame Julie Daran, Madame de St. Joseph, Duke of Connaught, Capitaine Christy, Annie Laxton, Céline Forestier, Madame Falcot, Royal Standard, Perfection de Montplaisir, Princess Mary of Cambridge, Souvenir d'un Ami, Prince Camille de Rohan, Alba rosea, Marie Baumann, Madame Caillat, Comtesse d'Oxford, and Mrs. Laxton. Those in pots were Souvenir de Louis Van Houtte, Madame de Montchauveau, Mrs. Laxton, and Magna Charta. I am very much mistaken if we do not find Mrs. Laxton to be one of the very best Roses ever introduced. In shape, texture, and colour it is all that can be desired.

Polyanthuses, or "Pollys," as they are familiarly termed in the north, were not as extensively shown as I had supposed they would have been. The principal exhibitors were Mr. Beswick and Mr. Dyson, the former taking the chief place, the chief flowers exhibited being George IV., Exile, Lancer, Cheshire Favourite, and Lord Lincoln.

I had intended to have made a few remarks of a general character touching the Auricula, but as the report has gone to some length I must reserve them for another paper.—D., Deal.

MESSRS. JACKMAN & CO'S CLEMATIS SHOW AT THE CRYSTAL PALACE.

A MOST excellent display of the Clematis was arranged by Messrs Jackman at the Crystal Palace last week. The Show will be continued for some time. There is very great variety among the spring-flowering section of these beautiful climbers. The plants are of medium size, the object being not so much to show specimen plants of magnitude as a well-assorted number of the better varieties.

Among novelties I was most pleased with Sir Garnet Wolseley, belonging to the Patens type section. The flowers are of a very deep blue in colour, the next approaching to the old Jackman, but much more beautiful in the way in which the petals are shaded. The Queen is an improvement on Lady Lonsborough. There are some good specimens of Vesta, Maiden's Blush, and Miss Bateman among the whites. Fair Rosamond and Edith Jackman are both very fine varieties. New varieties, to me at least, named Robert Hanbury and Countess Lovelace, are also very good.

Mr. Jackman has diversified his stands with pots of choice

Rhododendrons, and has most effectively introduced window boxes of Clematis combined with Pyrethrums.

The whole Exhibition is good and well worthy of notice, and will repay any florist who will take the trouble to go so far as Sydenham.—WYLD SAVAGE.

A MINIATURE HOTBED.

HAVING neither plant stove, hothouse, nor hotbed, I was until lately rather at a loss for means to strike cuttings and cause seeds such as Vegetable Marrows, &c., to germinate quickly, and have tried many plans, one of the most successful having been the following, of which I enclose a sketch (section).

Let the inner pot be nearly half full of corks, the remainder of course being earth, and the space between the pots filled with moss pretty closely. Well soak the whole, and after

Fig. 55.

A, Outer pot.
B, Inner ditto.
C, Cork in outer pot.
D, Drainage.

E, Earth.
G, Glass cover.
M, Moss.

thoroughly draining cork the hole in the outer pot. Sow seeds or plant cuttings in the usual way and cover over both pots with a piece of glass (for cuttings a common round-topped glass shade will be required), and put on the top of the kitchen range, oven, or boiler farthest from the fire, the heat arising from which will start them in a short time. I have started Vegetable Marrow and Cucumber seeds in three days.—COTTAGE GROVE.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PROVIDED the weather proves mild the planting-out of Celery for the early crops may be proceeded with. We plant two rows in quincunx order in a trench, the plants being about a foot apart. For early crops, however, we often resort to the bed system, the beds being 4 feet 6 inches wide, with 4-feet space between them. The plants are put out crosswise of the trench in rows 15 inches apart, and the plants 12 inches asunder. Those plants from seed sown early in March should, after they have been well hardened off, be pricked out 8 inches apart in rich light soil in an open situation, keeping them moist and shaded from bright sun until established. Instead of pricking off the plants they may at once be planted in the trenches at about 4 inches apart to allow for casualties, afterwards thinning them to a foot distance from each other. Vegetable Marrows and ridge Cucumbers plant out under handlights. We like to take out a trench about 2 feet 6 inches wide and a foot deep, filling it with hot dung and leaves about 6 inches higher than the ground level, and cover with the soil from the trench. The ridges are 6 feet apart from centre to centre; the Vegetable Marrows are planted 6 feet apart, and the ridge Cucumbers 4 feet apart. The Marrows are planted singly, and the Cucumbers in pairs. Potatoes above ground should be well hoed, and when they are 6 inches high earth them up moderately, making the ridges wide so as to allow plenty of tuberous space. If it is intended to crop between the rows with Broccolis, &c., the space between the rows should be well forked before the tops have spread much. Remove the flower stems from Rhubarb, cutting them back to the base. The young growths of Asparagus are often eaten by slugs. A dressing of salt at the rate of a peck per rod will destroy them and benefit the crop; but as slugs increase rapidly two or three applications of salt are necessary at twelve to fifteen days' interval.

HARDY FRUIT GARDEN.

Strawberries which have been forced may be planted out. The soil should be made quite firm about the balls and a good watering given. The plants will afford some fruit in late summer and an abundant crop the following year. If such varieties as Vicomtesse Héricart de Thury (syn. Garibaldi) be shaken out, potted, placed under a north wall until established, then stood in the open

and well supplied with water and liquid manure, they will fruit in autumn on shelves in a light airy house with a temperature of 60° minimum after they show for bloom. Established plants should not have the mulching delayed beyond the flowering period, and should be well supplied with water after the principal flowers open whenever the weather is dry. Carefully examine the foliage of all fruit trees, and if any caterpillars are found destroy them at once. Proceed with the stopping of the shoots of Apricots which are growing very vigorously. Nail in all well-disposed shoots, stopping all not required to three leaves, cutting forerights clean away; or, if the trees are very vigorous, that may induce "gum," in that case stop the shoots at the first leaf. The fruit from the abundance of foliage is now so well protected as to render the removal of the protecting material necessary. Thinning the fruit where it has set thickly should be attended to in good time. With young vigorous trees the fruit may be left 9 inches apart. It is the greatest of evils in fruit cultivation to allow the trees to carry too much fruit and to put off the thinning in fruit-ful seasons to a late period, which so exhausts the trees that they bear very heavily one year and are very nearly barren the next. Thin early: the fruit in its small state is good for culinary purposes; but some desire a full crop of tart Apricots, and expect fine ripe fruit, which is practically impossible. Allowing the fruit to remain on until the size of small walnuts takes very much more from the size of the fruit allowed to ripen than were they removed when the size of marbles. Peaches and Nectarines should be commenced disbudding, but it should be done gradually, commencing with the more forward growths. Retain a well-placed bud at the base of each bearing shoot to replace the one now bearing fruit, and another at its extremity to secure a due supply of sap to the fruit; this shoot should be stopped at the second or third leaf unless required for extension, when train in its full length. The shoots upon young trees should be disbudded to 15 inches apart, and there will be the bearing shoots next year; the shoots intended to form branches should be trained 12 to 15 inches apart, overcrowding tending to sterility and small fruit. Fan training is the most suitable. Disbud and regulate the young shoots of Vines against walls, and if mildew appear apply flowers of sulphur. Recently planted fruit trees should be well watered and be given a mulch of short manure.

FLOWER GARDEN.

Press of work at this busy season often causes the mowing of lawns to be neglected, which impairs their beauty throughout the season. This ought not to be, a well-kept lawn and clean smooth walks being indispensable to the enjoyment of the garden. The planting-out season being at hand we have a few remarks to offer—viz., Complete as soon as possible the final arrangements, make good use of the lessons gleaned during the previous year, but do not strive to imitate others; it is the way to be always behind your neighbours. Strike out into a fresh path, aim at originality, arrange the colours carefully. Place scarlet and yellow in the distance, and tone down homewards, and have at least one panel or carpet bed near home; it will always be appreciated, and especially when the flower beds have their gaudiness washed out of them. Do not be in a hurry to plant out, but have the plants well hardened off, and every fine day fork over the beds and bury the sun heat. It will add air and warmth to the soil, and where these are the plants thrive gloriously. Turning over the beds in the spring when the surface is warm is of more consequence than many imagine. It was a good and common practice of old gardeners long ago. Roses must be carefully looked over for maggot. Any leaf from its curled appearance likely to harbour the pest should be squeezed between the thumb and finger. This is a better plan than opening the leaf and picking out the insect, which can hardly be done without injury to the young foliage. Green aphides are often troublesome, infesting the young shoots. If they attack them before the shoots are of sufficient length to be dipped in tobacco water, apply the latter overhead on a calm evening through a fine-rose watering pot. Annuals require attention in warding off slugs and other predatory vermin. A sprinkling of soot over the plants during a calm evening or early morning will make them distasteful to the slugs. Dry wood ashes will check their progress, and a dusting of quicklime will destroy those it falls upon. When annuals are sufficiently large to be handled the plants should be thinned out, which will allow of them attaining to stronger growth and finer flowers. Sweet Peas when a few inches high require trellises or sticks of some kind to support them, as also do Nasturtiums (*Tropæolum*), and *Convolvulus* vars.

FRUIT HOUSES.

Figs.—In the earliest house the main object will be the ripening of the fruit, those highest in colour usually being highest in quality. A little air should be left on constantly day and night, and a free circulation of warm air secured whenever practicable. Syringing must cease when ripening commences, and must not be resorted to again until the crop is gathered. A superabundance of water at the roots will cause the fruit to be poor in flavour, but enough must be given to maintain the trees in a healthy state. If the fruit has to be sent a distance it should be gathered before it is quite ripe, otherwise it should remain on the trees for some

days longer—until it is perfectly ripe. If the second crop of fruit be very abundant it should be well thinned, or the fruit will be small besides impairing the energies of the trees for early work another season. Attend to stopping, thinning, and tying-in the shoots, cutting out the strong unfruitful growths in order to admit air and light to the fruit. Trees in borders of limited area will require water two or three times a week, and if the growth is not luxuriant and carrying a heavy crop of fruit the water should hold guano or some approved stimulant in solution. Syringe the trees twice a day.

Pines.—Fruiting plants with the fruit in an advanced state require a moderately high temperature and moist atmosphere to secure large well-finished fruit; but ventilation must be strictly attended to, admitting air at the top of the house at 80°, maintaining the temperature by day at from that point to 90°, or 5° more with liberal ventilation, closing at 85°. Early closing, too close and moist an atmosphere with a high night temperature, enlarges the crowns, which are generally quite large enough without needing any special incentive to growth. Unless ventilation is early and ample scorching of the crowns may result, and large or scorched crowns spoil the appearance of the fruit. Examine the plants twice a week, applying water only when it is required; it may be enriched with guano or some other manure, but let it be weak, and do not give it after ripening commences. Syringe plants and house two or three times a week, employing fire heat to maintain the temperature at 70° by night and 75° by day. The bottom heat keep steady at about 85°, not less than 80°, nor above 90°. Plants from which the fruit is cut may be placed in a light or part of the house by themselves, keeping the suckers on them for another fortnight, or until the end of the month, when they may be potted along with those held in reserve from March. Potting the suckers as the fruit is cut entails corresponding constant potting, which is not necessary to secure a supply of fruit throughout the year. Three general pottings of suckers are all that are required—viz., March, June, and September.

Cherry House.—The stoning will now be complete. If the crop be heavy and fine fruit are wanted thin the fruit, and as the syringe will be laid aside the roots of the trees must be well supplied with water, giving a thorough soaking to the borders, whilst those in pots or tubs will require daily attention, the roots requiring a plentiful supply of water for the perfection of the crop. Care must be taken not to allow the fruit to get wet, as may occur through the open lights in case of rains. Measures must be taken to exclude birds by netting of sufficiently small mesh to keep them at bay.

Melons.—Directly it is noticed that any of the fruit commences changing for ripening water must be withheld and the temperature increased, also the fire heat if requisite, so as to admit of freer ventilation, for nothing contributes so much to high flavour as a free circulation of warm air. The soil, however, must not be kept so dry as to affect the foliage, or the chance of a second and subsequent crops will be seriously impaired. The atmospheric moisture also must be lessened, and even withheld altogether if the weather is dull. If the plants are very vigorous it will be well to cut the fruiting shoot partly through when the fruit commences ripening, so as to restrict the supply of sap and prevent the fruit cracking. We find, however, that a close moist atmosphere is promotive of cracked fruit, which must be cut when the first indications of cracking are noticed. They will ripen in a warm dry atmosphere, but are poor in flavour. The fruit should otherwise be cut before it parts from the footstalk, but not until it is very nearly ripe, and may be kept in a dry room at a temperature of about 60°. Some experience is necessary to know exactly when a Melon is fit to cut; they have most flavour when under rather than over-ripe. Plants should be held in readiness to plant out in pits and frames as they are cleared of bedding stuff. Sow seed for late crops, as good plants planted out early in June will afford fruit of good quality in August onwards. Plant one plant in a light, disbud to four shoots, take two to the front and two to the back, impregnate the blossom when six or eight female flowers are expanding upon a plant, stopping the shoots one or two joints beyond the fruit. One fruit may be retained upon each primary shoot, four to a plant; but if large fruit are wanted two to a plant are ample. Overcropping is fatal to high flavour.

PLANT HOUSES.

Greenhouse.—*Cassia corymbosa* is fine for late summer flowering, and should be encouraged to make robust yet short-jointed wood by having a light airy position and as near the glass as the growth permits. It does not make a great number of roots, and should not therefore be overpotted nor overwatered. Light turfy loam with a little leaf soil and good drainage will grow it well. *Neriums* pushing the flowers must not be neglected for water or the buds will drop. Syringe freely to keep down red spider. Cuttings may be taken off plants that have been placed in heat for early flowers, but the shoots should be well ripened. Plants in 6 or 8-inch pots are very useful for decorative purposes.

Richardia athiopica.—Large plants which have ceased flowering should be divided, potting the suckers into 4 or 5-inch pots, to be placed on ashes in a cold frame, keeping them close and moist, encouraging growth for a few weeks, when they may be planted

out in heavily manured beds or trenches in the open ground, treating them very liberally with water. They will make very much stronger plants than if kept in pots, and the spathes are large in proportion to the strength of the plants. Instead of potting the plants may be hardened off, divided, and planted out at once in the open ground, lifting and potting them in early autumn.

Pelargoniums of the show and fancy kinds should have the assistance of liquid manure from the time the first flowers are set if they are intended to afford a succession of bloom. It is well to leave a little air on at night, as the sun falling powerfully upon the foliage whilst at all damp causes them to spot. Zonals for late bloom should be encouraged by shifting them into larger pots, removing the flowers as they show.

Tuberose after they throw up the flower stems should be assisted with liquid manure, keeping the pots upon a moist bottom, nothing being so injurious to these plants as dryness at the roots after the latter are well formed. They are light-loving plants and should be kept near the glass. A gentle bottom heat, such as that afforded by a hotbed, until the pots are well filled with roots, is requisite, potting in moist soil and not giving any water until growth takes place, then give very liberal supplies and also increased warmth. The keeping them near the glass will secure sturdy plants with well-developed flowers.

Azaleas as they go out of flower should have the seed pods picked off; they are unsightly, and impoverish next season's growth. The plants should be encouraged to make growth by keeping them somewhat warmer and more moist than during the flowering period, syringing twice a day, and affording shade from bright sun. It is a mistake to place them in houses densely shaded by Vines or Peaches, they not making such firm wood nor setting the flower buds so well as in houses with less shade. Similar remarks apply to the Camellia; all they require is to have the fierce rays of the sun broken so as to prevent scorching. Neither class of plants should ever be allowed to want for water at the roots.

Hardwooded plants are very effective for conservatory decoration, and if assigned a light airy situation will suffer no injury from a sojourn there during their blooming season, but they must be removed as soon as they are going off. Pimeleas are the better of slight shade from bright sun, also *Acrophyllum venosum*; indeed the latter does best in an old-fashioned house, but quite well in a light house if not kept too near the glass and slightly shaded. Young stock of hardwooded plants, such as *Aphelexes*, *Boronias*, *Choroemas*, *Croweas*, *Dracophyllums*, *Eriostemons*, *Epacrises*, *Gompholobiums*, *Leschenaultias*, *Polygalas*, *Tremandras*, &c., should be lightly sprinkled overhead every afternoon in bright weather, and the shelf or stage on which they stand should be well damped every evening, also the floors of the house, closing rather early with sun heat, but a chink of air should be left on at night, and additional ventilation should be given early in the morning. Slight shade from hot sun for about four hours will be beneficial; avoid, however, anything like gloom for any length of time, as it only induces weak soft growth which is sure to fall a prey to mildew, which must be destroyed upon its first appearance by being dusted with flowers of sulphur.

FLORIST FLOWERS.

Auriculas.—The time for repotting these is now at hand, for although some defer it until the autumn, the generality of growers pot their plants in May. The compost we use is three parts fibrous loam of the best quality procurable, one part cow manure well decayed, and one part of leaf soil from Beech and Oak leaves. The plants should be well shaken out, the pots cleaned, and great care used in potting. They should then be slightly watered, placed in a frame, and kept close for a few days. The larger leaves will gradually decay, but neither they nor the footstalks of the flowers should be rudely broken off.

Dahlias should now be hardened ready for planting out after the 20th, when we may hope all fear of frosts may be over. *Carnations* and *Picotees*.—Stakes should now be placed to the flowering shoots, whether grown in pots or beds, and the plants kept clear of weeds. Tulips will now be in the south coming full into bloom, and choice collections will be protected by a good awning; indeed without it, it is well-nigh impossible to grow them to perfection.

Ranunculuses.—The beds should be stirred over, covered and top-dressed with decayed manure. This will give them fresh vigour and prevent evaporation. They are fond of moisture, but it is better not to water if it can be avoided.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn, London.—*Catalogue of New and Choice Plants.*

William Bull, King's Road, Chelsea, London.—*Catalogue of New, Beautiful, and Rare Plants.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Bedding, Border, and Store and Greenhouse Plants.*

Stephen Brown, Weston-super-Mare.—*Supplementary Catalogue of Bedding Plants.*

W. E. Rendle, 3, Westminster Chambers, Victoria St., London, S.W.—*Illustrated Catalogue of Glass Structures.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (Etc).—The "Orchid Manual" published at this office will suit you, price 2s. 8d. by post free. (*Lincoln*).—Your query is rather indefinite; probably Tanner's "First Principles of Agriculture" would suit you. It is very clearly written, and explains much in a small space.

ADDRESS (G. C.).—Methven & Sons, Nurserymen, Edinburgh.

RAISING APOGONETON DISTACHYON FROM SEED (W. G.).—This lovely aquatic seeds rather freely and soon spreads, covering in a few years a large extent of surface. The seeds vegetate freely when dropped upon loam in a few inches depth of water. We do not know where seeds may be procured. Any of the principal nurserymen could supply plants, which are not expensive, also other hardy aquatic plants. We do not recommend dealers.

WINTER-FLOWERING PLANTS FOR COOL GREENHOUSE (Idem).—By "cool" greenhouse we presume frost is excluded. Plants of easy culture are—*Abutilon* *Boule de Neige*, *Acacia oleifolia* elegans, *A. platytera*, *A. armata*, and *A. Riciana*, *Chorozema cordatum* splendens, *Coronilla glauca*, *Correa* *Brilliant*, *C. speciosa* major, *Cytisus racemosus*, *C. Everestianus*, *Perseveria retusa*, *Epacris* in variety, *Eupatorium riparium*, *Cyclamen persicum* vars., *Primula sinensis* vars., and *Camellias*. Add to these Christmas Roses, *Laurustinus*, early-flowering *Rhododendrons*, *Dentia gracilis*, *Schizostylis coccinea*, *Primulas* denticulata, *nivalis*, *cortusoides* amena, and bulbs, not omitting *Chrysanthemums*, the grandest of autumn-flowering plants. No zonal *Pelargoniums* flower well in a cool greenhouse in winter. They require a minimum temperature of 50° to flower well, and then there is no difficulty in having flowers plentifully, the plants being young, well furnished, and not allowed to flower previously.

CINERARIA FLOWERS DISCOLOURED (Cineraria).—The flowers are discoloured by moisture having rested upon them during the night or for a lengthened period. The only remedy is to prevent water falling upon the flowers, and to admit a little air at night as well as day, with shade from bright sun. It is not unusual for some flowers to be affected while others escape; this applies not only to discoloration by moisture but from over-fumigation with tobacco. Were the plants having injured flowers so placed as to receive drip from the roof?

CHINESE PRIMULAS AFTER FLOWERING (H. S., Killee).—Remove the flowered trusses, and place the plants on ashes in a cold frame or outdoors in a position sheltered from winds and sun at midday. They should be kept supplied with water, and may be shifted into pots a size larger early in July. They will flower again in August and through the autumn, but are not so good as plants raised from seed sown early in the year and well cultivated.

SOWING PRIMROSE SEED (Idem).—Sow in the open air in an east or slightly shaded border at once, making the surface fine and covering the seed lightly with fine soil and keeping it regularly moist. It is not unusual for an *Anemone* to have the leaf below the flower.

VINES UNFRUITFUL (An Irish Subscriber).—The Vines making good growth yet not producing fruit would suggest that the wood has not been well ripened. Immature growth may be caused by a crowded state of the foliage, a deficiency of heat, or the roots having passed into wet soil. We should train the shoots thinly, stop them closely, and keep the atmosphere considerably drier, so as to favour the ripening of the wood. If these means fail the only remedy will be to lift the Vines and bring the roots near the surface. Is the house shaded?

PURCHASING ATRICULAS (W. C.).—In commencing a collection of Auriculas you cannot do better than order the plants at once of some florist who has them to sell, and he will send them as soon as they are ready—probably in June.

ROSE OF SHARON (E. S.).—Both a Lincolnshire vicar and a Lincolnshire gardener inform us that the St. John's Wort (*Hypericum calycinum*) is commonly known in their district as the Rose of Sharon. The seed you have received is possibly of this *Hypericum*; if so, it may be sown at once in light soil in the open air.

BRIARS (C. P.).—The most direct way of obtaining Briars for budding is through some of the nurserymen. If you live in a part of the country where Briars abound in the hedges and woods you could employ labourers who are out of work in the winter to collect them for you. We do not know the prices that are paid.

PEACHES AND GRAPES STONING (Cold).—It is not easy to give such instructions as you require without an object lesson. For a time after the fruit has set it swells regularly, but afterwards the swelling ceases, and for a week or more the fruit is apparently stationary. When swelling again commences, which is plainly perceptible, the stoning is completed. When the Grapes are as large as peas and the Peaches of the size of horsebeans examine them at periods of a few days, and you will not afterwards have any difficulty in detecting the stoning period.

INSECTS ON FUCHSIAS (L. F. O.).—Fumigation will not injure the Grapes unless you apply it too strong to injure the plants. Fumigate moderately two nights in succession, then syringe your plants with a solution of soft soap, about 2 ozs. to the gallon of water, and mix with each gallon half a pint of tobacco water. Apply it at a temperature of 100° and it will not leave any sediment on the foliage. If more convenient dissolve 2 ozs. of Gishurst compound in a gallon of water, and with it syringe the plants. Both mixtures are safe and efficacious.

PLANT FOR SCHOOL FLOWER SHOW (A School Girl).—If you will give us some data to guide us, such as the date of the flower show, the aspect of

your room window, and whether you require a fine-foliated or a flowering plant, we will endeavour to answer your question.

ROSES (South Hants).—The Shah cannot be termed a fragrant Rose: none of the Duke of Edinburgh race are full-scented. Prince Arthur we think is not fragrant; W. Wilson Saunders and John Bright are moderately fragrant, Mrs. Laxton has a peculiar perfume. As a rule, amongst crimson Roses the brighter the colour the less fragrant is the flower. Notwithstanding that the varieties are not fragrant they are yet admirable "garden Roses" in consequence of their excellent colours.

ASPARAGUS (A. A. M.).—Allow the small shoots to remain; it is only by permitting the growth of foliage that stout crowns can be formed for producing still stronger stems another year. The best book for you or your gardener is the "Cottage Gardeners' Dictionary," which you can have from this office free by post on receipt of 1s. 2d.

NAME OF FRUIT (W. Godwin, jun.).—We do not recognise the Apple. It is much grown in Lincolnshire, and is doubtless a good keeper.

NAMES OF PLANTS (H. S.).—3, *Erica Wilmoreana*; 4, *Erica intermedia*. We cannot name plants that are not in flower. (*W. H. W.*).—*Selaginella denticulata*. It no doubt wants repotting into fresh soil. You had better also propagate from the plant by taking off some of the shoots and inserting them into a compost of turfy loam and peat, and placing the pots in a shaded place and sprinkling frequently with tepid water. (*Somerset*).—They are both *Laurus nobilis*, but the one is a male and the other a female plant. That which bears the berries is the female. (*A. B. C.*).—1, *Orobis vernus*; 2, Can you send in flower? *Selaginella* shortly. (*A Mayo Subscriber*).—*Saxifraga granulata*, or a near ally; the *Spiraeas* seem to be rightly named. (*Us Garcon*).—2, *Saxifraga umbrosa*; 3, Apparently an *Andromeda* (*Lencothoe*); the Grass we cannot name from scrap sent. (*S. Morley*).—You must send better specimens; 4, is *Astilbe barbata*, often misnamed *Spiraea japonica*. (*A Boyle*).—*Limnanthes Douglasii*; try *Calla* or *Richardia*. (*Mary Duns*).—1, *Epiphyllum Russellianum*; 2, *Mesembryanthemum inclaudens* (*Bot. Mag.* t. 1863.)

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

MANAGEMENT OF LONG-WOOLLED SHEEP.

THESE breeds of sheep consist chiefly of Cotswolds, Leicesters, and Lincolns; there are, however, others, some of which are of a mixed or cross-bred origin. Either of these breeds of sheep are especially adapted for the home farm owing to their quiet and contented habit of feeding, and they will do well with cattle side by side, as they, like the cattle, will eat and lie down. This is particularly desirable in the home pastures or park lands for several reasons. The long-woolled sheep will in conjunction with cattle not injure the food like many of the short-woolled sheep, the west-country and South Downs especially, as these have a roaming and discontented habit, which in open pasture feeding spoils or renders the grass distasteful to cattle as well as themselves. The short-woolled sheep, too, usually in feeding gather together in flocks, and in consequence are not so ornamental as the quiet long-wools, which lie about and feed singly like the cattle, and are therefore more sightly objects in the park pastures. In order to make sheep profitable as well as ornamental on the home-farm pastures care should be taken to fairly stock the land—that is to say, the numbers of each should be adjusted to the acreage or area of grass land to be fed. It is also necessary to consider whether the sheep are to accompany dairy cows or fattening steers, because we always find it best to run ewes and lambs with the dairy cows, which only require short food, whereas a full bite of grass is necessary for the fattening steers, in which case the hogs or tegs will do well in the same pastures with the cattle, and both usually go to the butchers' market about the same time.

In the event of ewes and lambs being made ready for the butcher together when the lambs are about twelve or fourteen weeks old, it will be necessary to feed them separate from the cattle, and as they usually are allowed a liberal allowance of cake or corn or both they are mostly in such case kept on the arable land. We have often noticed in the western and midland counties that both Cotswolds and Leicesters do well with their lambs upon the clovers and one-year's lea, although the grass is often fed down very close and bare, taking off the young sprouted grass as fast as it makes its appearance. In this way with cake and corn they will come ripe for the market at a very early age. It is, however, a matter for consideration when it is required to fatten the lambs at the earliest age whether the same breed of tups should be used, or whether a tup of another breed should be selected. We have often found that the only point against fat lambs of any pure-bred long-woolled sort is the long and hollow coat, and this

is especially the case when there are a large proportion of twin lambs, and which is commonly the case with the long-woolled tribes, particularly of the Leicesters and Cotswolds. Now this is against their sale as fat lambs, for nothing is so taking in the eye of the butcher in buying lambs as a short close coat, and in order to secure this we recommend that a tup should be used of some short-woolled breed. In preference to a down ram of any sort we would use a well-bred horned Dorset ram. We have often known rams of this breed sent into the midland counties for the purpose of crossing with the Leicesters when the lambs are required for the metropolitan market at the earliest period. The advantage of this cross is, not only that the lambs will come to hand with short firm wool, but the horned Dorset and Somerset stock are noted for the number of twins they propagate. When first we heard of this cross many years ago we imagined that the lambs would come horned like the sire, because many writers when speaking of crossing give the sire credit for being the most impressive on the style of the offspring; but it is a fact that ninety-nine out of every hundred come polled lambs. This is altogether a very singular matter when we consider that the horned ewes when put to down rams for breeding early lambs also come polled in the proportion above named. This matter at first sight may appear to be quite unimportant, but it will be found that horned lambs never find favour in the eyes of the butcher. When this kind of stock is required for park lands it is not necessary to have the lambs to fall much before the grass comes ready for feeding; October will therefore be soon enough for the tup to be turned with ewes, after which it is of consequence to consider the best way of keeping the ewes so as to ensure healthy lambs.

The mode of providing for them will depend to some extent upon the proportion of arable and pasture land of which the farm consists. Where there is a considerable extent of arable land it is well to provide a good breadth of cabbages, for these are certainly preferable to either turnips, Swedes, or mangolds as food for in-lamb ewes, and it is advisable to hold a portion of the wheat eddishes, the clover seeds, and Italian rye grass for feeding during the autumn and winter months, so that the ewes may have daily a portion huddled off and also a portion of cabbages in the same way; field hay must, however, be used with cabbages after the grass is gone. If the fields are some little distance apart so much the better if the ewes are carefully driven by the shepherd. In our own practice we have always found that exercise in this way is favourable towards a healthy fall of lambs; and we must here mention particularly that we never allow a dog to be used by the shepherd, we prefer to have a strong lad instead to assist him. This not only gives better assistance to the shepherd than he can ever have from his dog, but it is at the same time bringing young men forward to take the position of shepherd at a future time, a matter of no slight importance in view of the labour question as it at present exists; for although the labour of the farm in many cases may be done by new implements, yet the duties and requirements of the shepherd cannot be carried out by machinery. Again, where the home farm consists principally of pasture the ewes will not have the advantages of the change of food as upon farms with a due proportion of ploughing land, but must be kept more upon grass, still a portion of the arable should be cropped with cabbage. Ergot is often found in pasture hay, but not so often in field hay, because field hay is usually cut and made before the seed of the grass is formed, but not so with pasture hay; for it being composed of a variety of sorts of grass, some early and some late, it often happens that some sorts are seeded enough to be attacked by the fungus, particularly in moist seasons of low temperature. In order to avoid the formation of ergot it is best, instead of feeding with hay, to carefully preserve grass in portions of the pasture land which may have been fed down bare up to the month of August and upon any dry soil. The grass which will be produced after that time will furnish the very best of food for pregnant ewes. When the tup is turned with the ewes at the time above named the lambing time will not be generally attended with so much risk as when it occurs during the dead of the winter; it will therefore be quite sufficient, where the pastures are at all sheltered, to keep a shifting fold on the driest part of the pasture, and if it is of a south aspect so much the better. It will, however, as it always must be, necessary for the shepherd to give all possible care and attention at lambing time both by night and by day, for although it is reasonable to expect that the worst winter weather will have passed away, yet the usual casualties of the lambing season must be reckoned upon.

The mode of management of the young lambs having been treated of in a former article upon down sheep we will pass on to the period when both ewes and lambs will be strong enough to commence feeding the pastures with such assistance as they may require, according to the object in view, whether of fattening the ewes and lambs together or be retained and kept only in store condition, the lambs being fairly fed with the view of the wether lambs being fattened at eighteen or twenty months old, and the ewe lambs being weaned and pass into the flock to be maintained for future breeding purposes. In either case the lambs will begin to eat before the grass will be entirely sufficient, and to

maintain them in condition with assistance by root-feeding and with artificials such as best American oil cake, bean meal, or cracked peas. Here again we find, after the cabbages are gone, the best food for young lambs is firm and hard white carrots, and when passed twice through the cutter and mixed with finely ground cake and bean meal they will eat such food at the earliest period. Swedes cut in the same way will answer in the absence of carrots, but we do not approve of mangolds for lambs either for fattening or otherwise until a later period and after the lambs are weaned. The weaning of lambs is of some consequence, for when they are removed from the ewes it is difficult to get them to feed properly for some days; we therefore prefer to remove the ewes from the lambs, allowing them to remain on the ground where they have been lately fed; in this way they remain much more contented, being also fed upon their accustomed food.

Having referred to the rearing of fat lambs to be sold early we will now consider the rearing of lambs for stock to be held on in store condition, and sold or kept for fattening as tegs or wether sheep. In breeding lambs to be reared as stock the best plan is to use the down tup for the purpose of crossing with the long-woolled ewes, as this mixture of blood effects a great improvement in the value of the stock by not only making a great weight of mutton at a given age, but by producing it of better quality as compared with the long-woolled breeds. The crossbred animals are therefore more inquired for by the purveyor, who is induced to give a higher price for the animals in the live market, and but little below the value at which pure-bred down sheep are sold. Before concluding the subject we must remark that when it is required to maintain a long-woolled flock in all its purity of blood it is necessary in a great measure to adhere as much as possible to the best type of animal, which matter must always remain a question of selection by the farmer, and having once made a suitable choice of animals adapted to the soil and climate upon which they are to be kept it will be desirable to breed from the same blood. Although this is commonly called in-and-in breeding, yet it is preferable to taking stock for continuing the stock, of which you may know but little or nothing of their origin. It is, however, necessary in purchasing tups or ewes for maintaining the flock to select stock of same origin, but having been reared and fed in a different district; following this plan will give all the advantages of in-and-in breeding under a skilful selection without the disadvantages.

WORK ON THE HOME FARM.

The horses will be employed where the Lent corn is all sown and the land seeded to clover and grass, and in preparing land for mangolds, and drilling as soon as the ground is ready. The season for mangold sowing cannot longer be deferred without some disadvantage, for although extra manure applied will force-on a later-sown crop, yet there is more probability of obtaining full crop when early sown. The preparation of the land for Swedish turnips should now be proceeding as soon as the mangold ground is finished; in fact, it will be going on simultaneously or alternately. Sometimes the work of carting-off couch and weeds may be done on one piece, whilst ploughing, harrowing, &c., may be proceeding on another field, an alternation in the work being sometimes favourable, unless the weather proves very dry, in which case the quicker one sort of work follows on the other the better, because it does not give time for the land to become hard and rough.

Hand labour will now be required in sowing artificial manures on the wheat, Lent corn, or grass, whichever may require it. If nitrate of soda is used a dry day or two is best for it, particularly when salt is mixed with it, but when guano is used it is best to sow it whilst the land is damp and moist, and in order to prevent its driving before the wind moist ashes should be mixed with it. Should the men be driven to the homestead by showery weather, work should be looked out for them under cover: they may prepare and break guano, and put by in bags of 2 cwt. each in readiness for use. It is well for the odd horse when at leisure to bring home to the farm buildings a few loads of sand. It should be soft yellow sand, not sharp white sand. This will be ready for various purposes, amongst others that of mixing with half-inch or ground bones, for we cannot help recommending an old plan, notwithstanding that we can get bone superphosphate ready made for use—that is, to take an equal number of bushels of ground bones and of sand and mix them together, and at the time of mixing to add water until it becomes a mass like mortar; it will absorb a considerable quantity of water, which should be continually added until it runs away freely from the mass. It will then be in a condition to heat and rot the bones in heap, the heap to be made up in a conical form, and covered over about 6 inches thick with more pure sand and beaten down firm with the shovel. At the end of about three or four weeks the bones will have become partially decayed, and the sand will then be of a dark colour, showing that it has absorbed and fixed the ammonia whilst the bones were rotting. In order to reduce all the bones to the desired state of decomposition the heap should be turned once or twice, adding water as before, then make-up the heap again and covering it with another layer of sand. At the end of about a

month the heap will be ready for use, and a capital manure it is, either for drilling with mangold, Swedes, or turnips, and likewise for sowing broadcast upon pasture land. It is, however, especially adapted for drilling to manure the root crops, because the sand being a maiden earth it is well fitted for the rootlets of the infant plants to feed upon, more particularly as the sand is enriched by absorption of manure from the decaying bones; besides which the structure of the bones will be completely broken down and become available as food for plants, in the same way as bone or superphosphate, and better in some respects, as it will contain a considerable quantity of ammonia imbibed by the sand. We have sometimes found that parties use ashes, peat, or sawdust. Anything that will ferment with the bones will answer the purpose of decomposing the bones; but sand is the most useful adjunct, and it must be borne in mind the larger the quantity of bones and sand in the heap the better, because the larger heap will ferment and decompose the bones better than a smaller quantity.

Women will now be employed in weeding, which may be done with an ordinary spud for cutting-up the annuals; but for the strong-rooted weeds such as docks, which now begin to make their appearance, a small pickaxe is best, pointed at one end, and a cutting-edge about 1½ inch wide at the other. By loosening the ground round the roots of the weeds they may be rooted-out entirely, or cut off much below the surface and destroyed. Thus it will be seen that the pickaxe answers the purpose for destroying all kinds of weeds, but the small spud is only useful to destroy annuals. These implements for weeding must be made light and handy for women to use (yet strong enough for the purpose), otherwise the women who have only been used to the light spud will object to use them. The horse-hoeing of peas, beans, wheat, &c., must be done the first dry weather, and it is important that this work should be done whilst the plants are young and before the weeds get very strong. Some farmers object to early hoeing, saying there is nothing to do the weeds are so small, but we consider it so much the better, because if the land is hoed whilst the weeds are in their infancy they are much more easily killed; therefore the first dry weather should not be lost, for in some seasons by waiting the weeds get strong, and if wet weather follows the hoeing many sorts will not die off as required.

PRIZE POULTRY.

THERE seems no limit to the credulity of the British public. In most things we are willing to profit by the experience of our forefathers or neighbours, but when some incredible advantage is offered, or some ware is advertised of a cheapness so startling as to seem contrary to the principles of political economy, then the major part of us refuse to be guided by the experience of others, however disappointing it may have been, and prefer each to buy it for ourselves, and that often at a singularly high price. Were it otherwise the company of the quacks, from the Mesdames Rachel downwards, would be far smaller than it is and meet with far less encouragement. The question of imposition in the abstract is not within our province, but so many practical examples of it in the poultry line have of late come within our notice that we think it incumbent upon us to say something on the subject. Advertising columns are week after week crowded with lists of "prize" poultry and Pigeons for sale of such length that a foreigner might well conclude that poultry showing was the chief occupation of Englishmen, and that the number of our shows must be simply infinite. A large margin must of course be allowed for the ignorance of advertisers, some of whom are probably under the misapprehension that the term "prize poultry" includes any birds of pure or tolerably pure breed. As instances of this *bona fide* ignorance we may quote one or two cases that have happened to ourselves. An advertiser, through a well-known medium for the disposal of all possible and impossible things, offered not long ago, we believe in perfectly good faith, a "splendid prize cock" of a variety which we wanted. We asked for further particulars, and were informed that the bird had never actually been shown, but was considered a "prizetaking" bird, as it came from eggs bought of a lady who originally had her stock from "a lord" who had frequently taken prizes at Birmingham! Again, in distress for broody hens we answered a most promising advertisement from a lady offering them at 5s. each. We naturally inquired how long they had been sitting; the reply was that they were not sitting at all, but were of a kind specially calculated for brooding chickens. Why a China egg should have been offered with each hen did not transpire; perhaps to teach them the act of incubation by the way. Leaving, however, as we said, a large margin for these cases of *bona fide* ignorance, there still remains a large residue of cases in which birds are sold and bought as prize birds which have taken no prizes at all nor are ever likely to take them, besides numbers which have received notices at little local meetings that are no guarantee of their merit and should not enhance their value. We have lately visited the yards of several beginners who wished to start with well-bred birds, but did not feel inclined to give long prices for them. We have actually seen Buff Cochins with long featherless legs, deeply striped neck hackles and lapping combs; Brahmas with five claws, and Dork-

ings with four—all "prize poultry!" Now, as long as there are ready purchasers for such rubbish so long is the market sure to be well supplied with it; we will therefore attempt to give a little advice to that large and daily increasing class of fanciers who wish to obtain well-bred poultry, though not specimens of the most perfect exhibition type.

To begin with, we may remark that a prize card is a very relative honour. There is a difference between shows that can scarcely be appreciated save by those who have had some experience in them. We could without over-refining divide those which are advertised and tolerably well known into at least five classes of merit. The first-prize birds in the lower of the classes of shows would, as a rule, have little chance of a bare commendation at those of the first class. We have often seen small shows where the judge had simply to choose the birds with least glaring faults, even for a cup, and where we would not have taken the highest winners at a gift. Far be it from us to depreciate the use of shows as a valuable means of comparing high-class stock and as giving a stimulus to its cultivation. A notice at a first-class show is a great and generally a reliable guarantee that a bird is a good specimen of a certain distinct type, but purchasers are too apt to think that a prize card wherever obtained gives intrinsic worth to a bird. Doubtless it always does add a certain saleable value, but often unjustly so. Even in the best shows too much value is often placed on position. Judges are not infallible, and so carefully are the more favourite kinds now bred that there is often little to choose between six or eight pens in a class at the Crystal Palace, Oxford, or other great shows. Still we find £10 more readily given for a first-prize winner than £5 for a third, though the few really discriminating purchasers often give far higher sums for even an unnoticed bird than are placed upon the winners. One of the first things to be remembered by a would-be purchaser of high-class poultry is this—the principles of atavism (to use a word of modern coinage), or the return in the produce to the type of their ancestors, are at present very imperfectly understood; still, this much we know, that many generations of breeding to some particular stamp are necessary before we can have any certainty as to the produce. People talk of purity and impurity of breed without considering that these terms are necessarily relative, and without having any idea as to the number of generations of one particular type which they would consider to constitute a pedigree of purity. Those who have attempted to breed on anything like scientific principles well know how very many are required, and how unjust it sometimes is to attribute fraud to those who have sold birds which do not quite reproduce their like. What, however, we specially wish to deduce now from these facts is, that it is far better if possible to buy from yards where it is known that certain varieties have long been carefully bred, even though only faulty specimens from them can be afforded, than to buy veritable prize birds which have been produced in a happy-go-lucky manner. Great harm has been done by the necessity of what is called "introducing fresh blood" being exaggerated. It is true that now and then by a fortunate chance some indiscriminate union of birds from two dissimilar strains has had a good result in the first generation, but generally in the second and third it is an utter failure.

Our first piece of advice, then, to those who wish to get up a good strain of any kind is to eschew these cheap so-called "prize birds," and to go to an old-established yard for stock to start with. We have done this ourselves with several varieties, and have so formed famous strains at little original cost, save that of intelligent and scrupulous care in breeding and accurate noting of pedigrees. For the most part, of course, the yards of those who have long exhibited particular varieties will be those to select from, but we know others who do not show at all and yet have by no means despicable studs long bred with care. Furthermore, when once a particular strain has been chosen we advise the fancier to keep to it. Where it has been carefully kept up there are sure to be several families, and when "fresh blood" is really required a reliable fancier will select birds for a purchaser not too nearly related. In this way a vast amount of disappointment from the produce of raw and ill-judged crosses will be avoided. Certainly a prize bird for 7s. 6d. sounds most tempting, but such bargains are generally dear ones and often spoil the whole produce of a year. We do not for a moment mean to deny that many good and reliable prize birds are advertised and sold.

It not unfrequently happens that a beginner wishes to make his or her *début* at some country show, and for this object tries to get some "certain winners." Our counsel to such is, Go to the most reliable and famous breeders, state exactly the purpose for which you require birds and the time of the show. Prize birds at even a first-class winter show are often utterly unfit for even a local show by the summer. We believe that there are very few breeders of eminence who will not do all in their power to help a beginner. "Perfect birds" which are so frequently asked for at 5s. a head, of course they will not sell for £1 or £2 each, but they will generally describe honestly what they have to spare, and state the faults as well as the excellencies of the birds. It is a great error on the part of beginners to expect to find or even to ask for perfection. The honest seller at once replies that he has

not such birds, and if he had could not sell them save at extravagant prices. The dishonest advertiser offers in reply stock with every conceivable merit for next to nothing. If purchasers would but listen to these hints, and be less sanguine in their expectations and more discriminating in their purchases, we should not hear of so many disappointments, and the trade in spurious "prize poultry" would be appreciably checked.—C.

WHARFEDALE POULTRY, &c., SHOW.

THIS venerable Society held its eightieth Exhibition on the 4th and 5th inst. The first day was devoted to agriculture proper, and the second set apart for dogs, poultry, Pigeons, and Rabbits. The entries were very good throughout, and the quality was likewise very high. The day was fine and the visitors numerous. The pens were those of the Society; they were of wood with wire fronts and moveable tops, and in consequence the birds were very easy to handle.

Game headed the list, the first class being Black Reds. The first cock was a stout well-built bird, sound in feet and in fine order, but the hen a little rusty; second a capital pair; the third best except that the cock's eyes were too light. Brown Reds.—First a good even pair in fine order, and the cup was awarded to them; second good, but the cock a little coarse; the third grand in quality, but small and young, and the cock out of feather. The three following classes contained but few birds, but the single Black Red cocks were good. Single cocks of any other variety.—First a grand old Duckwing, second and third Piles. Single Red Game hens were the best class in the Show, scarcely a bird but what was well deserving of a good position, the winners being Brown Reds. Hens, any other variety.—First a Pile in the pink of bloom, second a fine Duckwing, and third also a Pile. In the large section of poultry—viz., Spanish, Dorkings, &c., the cup was awarded to the pen of Spanish containing the celebrated hen of which there has been so much controversy as to her proper sex, the second being a fine even pair. *Brahmas* were pretty good in both classes, though some of the Light cocks were very yellow. *Dorkings* were excellent, large and good in feet. *Polish*.—First Silver, and second and third Gold. The first-prize Golden-spangles were sent all the way from Cornwall, and were a capital pair. The cup was awarded to Silver-spangles, the hen being superior. Gold-pencils.—First a pen containing one of the neatest cocks we have yet seen, but most of the hens were a little faded. Silvers a moderate lot. Black Hamburgs were about the best of the Hamburgs, and in good bloom throughout. Hen-feathered cocks produced six entries, and we are glad indeed to see this most useful and handsome variety again encouraged; the first was a Silver-spangle, and second and third Silver-pencils. *Game Bantams*.—Black Reds were very good in style, but some of the best a little large. Brown Reds were the best class we have seen of late, the cup for Bantams being awarded to a capital pair, except that the cock was rather short in head. Any other variety.—First and second Duckwings, and third Piles.

Rabbits were a capital entry, the classes averaging fourteen in each, for 15s., 7s. 6d., and 2s. 6d. as prizes. Lops were first; the winner, a Fawn doe, of grand all-round merit, 23½ by 5½ inches; the second a Tortoiseshell, 22½ by 4½ inches; the third a Fawn, 25 by 4½, but not near so good in other points. Angoras were a very even class, but many were very badly mated. The winners were very fine in fur and well shown, though young and not full grown. Silver-Greys were the best class in the Show; the first quite young but of exquisite ticking and silvery, though slightly clouded on the head; the second more even on the head, good throughout, but not as sharp in silvery; the third a large well-silvered doe in capital order. Himalayans were a smaller class, the winners good in points. The Variety class was a good one, almost every one being noticed; first a very rich-coloured Silver Fawn, second Grey Dutch, and third a large Belgian Hare, failing only slightly in ticking.

Pigeons were a nice lot, but in some cases the birds were bad to get at, the doors of the pens being at the back. *Pouters*.—First a Red, and the other winners Blue. The cup for the best Pigeon went to a capital Black Carrier cock. The cup for the best, entered for sale at £6 6s., was again won by the donor, Mr. Horner, no one caring to enter good birds at such a price. In Jacobins Reds were first and third, and Black second. *Dragoons* were a superior class, and more might have been noticed. Almonds won the prizes for Short-faces. *Turbits* a fair lot; first Blue, second Red, and third Silver. Six classes were provided for Antwerps, and these were well filled, showing the popularity of the breed. In the Variety class a Spangle Ice was placed first.

POULTRY.—GAME.—Black Red.—1, J. Fletcher. 2, H. Hick. 3, J. Craven, *etc.* T. Dyson, W. Rudd. *Brown Red*.—Cup and 1, W. Rudd. 2, Weeks and Etheridge. 3, W. A. F. Fenwick. *Duckwing*.—1, W. CROSS-BREEDING RABBITS.

I AM a breeder of the Silver-Fawn Rabbit, and have been for years, and the first I ever bred were from Silver-Greys of the purest prize strains that could be obtained, and this leads me to think that the Silver-Fawn is simply a sport from the Silver-Grey in the same manner as a white Blackbird, white Sparrow, white Crow, &c., all these differing in certain respects from their parents—i.e., colour, &c., which is precisely the case with Silver-Fawns, for they agree exactly with the shape, size, colour of eye, &c., of the Silver-Grey, and differ only in the colour of the ground fur, which in the case of the former should be a rich fawn, and the latter a slate blue. "GETA" asserts that the Silver-Fawn is now a distinct variety, and if paired with Silver-Greys would throw them too mealy. This is wrong. Silver-Fawns are not bred together, but are always (to obtain the proper exhibition shade) crossed with Silver-Greys, otherwise they would have the same fault as "GETA" ascribes to the crossing of Silver-Fawns—viz., too much meal.

The best way to breed Silver-Fawns possessing at once richness in fawn and silver ticking (which is essential before a Rabbit of this breed can be put into a show pen) is to put a Silver-Fawn buck to a dark even-shaded Silver-Grey doe, if possible Fawn bred, and amongst the produce will be least 50 per cent. of Silver-Fawns of a rich shade.

"GETA" does not mention a cross from which there might be a variety produced never yet seen in a show pen. That is Silver-Grey Dutch. This might be produced by putting a Black-and-white Dutch buck to a light-shaded Silver-Grey doe, and selecting the best marked young ones and putting them to Silver-Greys. Out of this mixture select the best, and put them to Dutch, and so on, until the breeds were thoroughly intermixed.—EDWARD MCKAY, 5, Station Road, Darlington.

VARIETIES.

As soon as we discover any symptoms of gapes among our chickens we know that there are worms—very small red worms—in their windpipes, and we give them camphor in their drinking vessels strong enough to make quite a taste of the camphor. Then if any get the disease quite badly before we discover it, we force a pill of gum camphor down the throat about the size of a small pea, and the fumes of that dose will kill the worms. No kind of worms can live in camphor.—(*Poultry World*.)

—**BOXES FOR BIRDS' NESTS**.—Some of the Berlin papers report the most favourable results consequent upon the novel introduction, at the suggestion of the respective school boards of different districts of Berlin, of small boxes or caskets destined for the shelter of birds, principally starlings. Koeniggratz and

Neustadt, two school board districts of Berlin, have entered with great zest into this movement. Some 6000 such baskets and boxes for starlings have during the winter been fastened and hung up in every available position in the district of Koeniggratz alone; and as many as 11,862 boxes, each of them now occupied and inhabited by a family of starlings, have been likewise distributed and hung up in the district of Neustadt for the purpose of giving shelter to the birds during the hardness of the season, and preserve their, to horticulture and agriculture, so valuable existence.

— *THE American Cultivator* gives the following good advice on feeding poultry:—Where fowls have a free range it is the most economical to feed them twice a day. The fowls should be let out early in the morning; in fact, if there is no fear of enemies or thieves the hen house had better be left open, so that the birds can come out at will. This they will do at daybreak, and by wandering over the fields secure a large amount of worms and insect food. They should receive their morning meal at a fixed hour, and immediately after breakfast is usually a convenient time. So much depends on the size of the birds that it is impossible to give a precise rule as to the quantity of grain to be given to each. It is obvious a Dorking of 10 lbs. weight and a Game fowl of 4 lbs. would require very different quantities of food. Again, more food is required to keep up the due amount of animal heat in winter than in summer. When a hen is producing eggs she will eat nearly twice the amount of food that she requires at another time; hence the successful poultry breeder will need to observe carefully the requirements of his fowls, and govern himself accordingly. The best rule, both as to quantity and time, is to give the fowls a full meal in the morning, and a second shortly before going to roost. There is one important advantage dependant on having fixed hours of feeding—namely, that the birds soon become accustomed to them, and do not hang about the house door all day long, as they do if irregularly and frequently fed. They consequently obtain a greater amount of food for themselves and are less troublesome than they otherwise would be.

— *MUCH* of the prevailing taste and fancy in Europe for some of the popular cheeses must, says an American writer, be wholly acquired. In some English dairies the leaves of sage, parsley, and other herbs are infused into cheese to give it a green colour. In other dairies part of the curd, when ready for the press, is exposed in a sieve to the air, in order that it may become oxygenated and may render the cheese, into which it is mixed with newly prepared curd, of a diversified colour and of a tendency to run speedily into putridity. In a few dairies rapid putridity is induced by an intermixture of beaten potatoes. In Ross-shire cheeses are for several days buried at the seashore, in order that they may acquire a blue colour and a peculiar taste; while in France a considerable quantity of cheese receives an offensive smell, resembling that of a pigsty, from the intermixture of fenugreek.

— *THE American Cultivator* in alluding to the slow or complex methods of testing milk speaks favourably of Professor Feser's improved lactoscope. This lactoscope consists of a glass tube about 11 inches long by 1½ inch in diameter, except at its closed end, where the diameter is greatly reduced. Attached to the bottom of the inside of the tube at a fixed distance from its sides is a short white porcelain rod, on which several black lines are enamelled. The tube itself is graduated in cubic centimetres (0.893 inch), and also bears a scale registering the per-centage of fat contained in the milk under examination. To find this a small quantity—about four cubic centimetres (a cube of about 1½ inch)—of the milk, which must previously be thoroughly stirred up, is introduced into the tube, while water is added little by little till its opacity is so reduced that the black lines on the rod become visible. By reference to one set of graduated marks on the tube it may be ascertained how much water has been required, while the other records the corresponding per-centage of cream present in the samples. The richer a milk is the more water will it require for the completion of the test, while the more it has previously been watered or deprived of its cream the less additional water will be needed to bring the black marks in view.

A STEP IN ADVANCE.

"J. R.," who has been a bee-keeper and reader of the *Journal of Horticulture* for many years, wishes to replace his old straw hive with one that would be profitable and simple to work at moderate expense, and would be happy to adopt any suggestion likely to be a step in advance of the old straw hive. Our correspondent is not alone in wishing to get a step in advance of existing hives and practices, for that is what many apirians are aiming at and making great efforts to reach. "J. R." must have seen in this Journal's pages recommendations of many kinds of hives and pretty full descriptions of them.

The bar-frame hive has been for many years strongly recommended by many bee-keepers, and the mode of working it has been fully explained; and all this may be said of the Stewarton hive. A good hive of either the Stewarton or bar-frame school costs between 20s. and 80s. We recommend our correspondent to

try both hives, and thus find out which is the most profitable and simple to work. Of these two hives we should prefer the Stewarton for several reasons. It is better adapted for supering, ventilation, and enlargement, more natural to the bees, and more easily and successfully worked by the bee-master. I think it is "a step in advance" of the bar-frame hive; and it appears to me that the bee-keepers of the Stewarton school have greater confidence in their hive and system of management than the bar-frame school have in theirs, and we cannot help attaching some importance to this confidence. We read of no efforts being made to improve the Stewarton hive, whereas almost every advanced bee-keeper of the bar-frame school is trying to improve their hives or to remove difficulties and drawbacks in their management.

One gentleman in trying to improve the hive has united, or fancied he has united, both systems in a pretty and rather expensive hive called "the Carr-Stewarton," which, in our humble opinion, is not a step in advance of either of the hives. I commend the principle or mode of managing the Stewarton hive to the consideration of the bar-frame school. The bar-frame hive is not made or meant for enlargement by eking or additions, and this in the eye of practical management is an evident and serious defect; but doubtless our friends of that school, who are looking ahead and seeking improvement, will strike on some idea that will be a step in advance of their present practice. If we were working bar-framers we would use two hives in one, by removing the crown board of the bottom hive and placing the other over it.

One word more in answer to our correspondent's letter, which says that in order "to get a little honey from straw hives we have to call to our aid fire and brimstone." I am sorry to learn that he resorts to such practices, for hundreds of poor cottagers and many ladies of position can take honey from straw hives without the use of fire and brimstone. Having taken honey for fifty years from straw hives without the destruction of bees, and having taught hundreds if not thousands of bee-keepers to do the same successfully, our friend will excuse me if I venture to tell him that if he cannot handle bees in straw hives and take honey from them without fire and brimstone the probability is great that he will be in the same fix and difficulty when he shall have adopted another kind of hive. Both skill and courage are necessary in managing bees, and without these a change of hive or system of management will not help us much.—A. PETTIGREW.

SWARMING VERSUS NON-SWARMING.

It afforded me pleasure to find your correspondent "B. & W." had accepted my remarks under the above heading in the same fraternal spirit as they were tendered; true it is we travel the same road, my sole aim being to show that that road leads on many stages beyond natural swarming. The apirians readers of this Journal are much indebted to your able contributor for so clearly demonstrating the superior advantages of wooden hives, and aiding to remove the antiquated prejudice that bees can only be successfully kept by "the old skep fashion," which as a swaddling band has too long kept apiculture bound in its infancy. Had he but further taught that the inconvenience and loss of time to both bees and their keepers by natural swarming, or as part and parcel of the straw-skep system, from which those keeping their bees in boxes were happily relieved. As bearing directly on the point at issue, I may be permitted to quote verbatim from a quaint old author. Dr. Warder, in his "True Amazons," writing more than 150 years ago (1726), says—"Thus having given directions how to manage your bees in straw hives, which I was willing to do (because most of the people of England will never attain to the keeping of them in boxes), for two reasons. First, Because 'tis a hard thing to put them out of their old road, which every old woman thinks she understands; and secondly because it is a more changeable way than the other, and therefore they cannot attain thereunto."

"I shall now go on with my design in teaching the way to keep bees in boxes or colonies, which is more pleasant and profitable than the other, and more merciful, because in this way which we are about to treat of we kill no bees, yet have great quantities of honey."

The non-swarming system, or that of keeping bees in colonies, is by no means a modern idea in these northern regions, for it is recorded more than two hundred years ago in the "Philosophical Transactions" of Gresham College with regard to the octagon hive—"A bee hive useful to prevent swarming, and used with success in Scotland." Its history in the south is interesting, the invention being attributed by Hartlib to the Rev. W. Mew, minister of Eastington, Gloucestershire, so far back as 1653. The afterwards celebrated Sir Christopher Wren, then a young man of twenty-one, had turned his attention to its improvement, first recommending in a letter the following year the doubling of swarms to stock it. Twenty-two years after the invention seems to have been basely pirated by John Gedde, who alleges to have then obtained a patent from Charles II., styling himself as "Gent. Inventor;" while Moses Rusden, the apothecary of Bowling Alley, who sold licenses to use the hive, confesses in his book published in 1687 that he had just seen the octagon hive in possession of Dr. Wilkins

Bishop of Chester! Subsequent writers' description show the hive of Mew little altered from the first.

So far as I have been able to trace, an Ayrshire man, Robert Kerr, cabinet maker, Stewarton, a keen bee-keeper, and at the same time a most ingenious mechanic, about the year 1819 revolutionised the octagon hive, now known as the Stewarton, by closing up the large square central communication and clothing each top with $1\frac{1}{4}$ -inch fixed bars and moveable slides between working in grooves therein, which materially facilitated communication from box to box. He, too, introduced the separate honey-compartmental arrangement, by which the pure virgin nectar was stored in a series of shallow supers; free communication between each of those by the same $1\frac{1}{4}$ -inch fixed bars and slides, and the admission of the honey gatherers solely by the end spaces, was a most invaluable part of his plan, thereby circumscribing the movement of the queen and her attendant train of nurses and pollen collectors to the central brood-bed. When first that hive came into my possession some twenty years ago, I tried to further improve it by increasing the depth of the breeding boxes, removing the broad $1\frac{1}{4}$ -inch bars and substituting those $1\frac{1}{2}$ wide or $1\frac{1}{4}$ inch from centre to centre, so that I might have the combs with guide built perfectly straight, and each attached to but one bar, and further on substituted frames for bars, so as to make every comb moveable and interchangeable from hive to hive, coming up to your correspondent's Ne Plus Ultra, a hive expandable with the season and of easy contraction at its close; but I overlook "B. & W.'s" stipulation was expandable in "every direction." He says, "Such a hive has yet to be invented, if, indeed, it be within reach of the possible." A hive exactly answering his description combining the storifying and collateral systems, I invented and not a little proudly wrought in novitiate days. When my central stock, or Pavilion of Nature, as styled by Nutt, got crowded, I simultaneously opened communication with super and end box; but the heated atmosphere would ascend, and with it went my little favourites to take possession, leaving my well-ventilated end apartments utterly untenanted. Feeling annoyed at their seeming perverseness, I would shut them out, the super forcing them as it were into the side compartments; to my surprise found their first act was to propolis up the perforations in the ventilating tubes therein. I thus saw the absurdity of Nutt's theory, and taking the hint have ever since carefully wrapped up all supers with warm woollens with the best results. From experiments with this hive became thoroughly convinced that bees will extend their works much more readily in an upward or downward direction than laterally.

Your correspondent's lack of success with the non-swarming system I have no doubt arose, in common with many others, from the want of a hive wherein a due proportion of breeding and storing space could readily be maintained. We storifiers never expect to find honey in nadirs, that being simply an extension of breeding room, but by the honey gatherers bred therein a large augmentation of that nectar in the supers.—A RENFREWSHIRE BEE-KEEPER.

FEEDING BEES.

I SHOULD be glad to know whether you really agree with the suggestion that lately appeared in your columns for feeding bees on barleysugar. I have kept bees with more or less success since 1858, but I have not been able to devote sufficient time to the work to enable me to render reliable notes on the subject. I have always considered the insect as unable to assimilate solid food; therefore I presume if bees can eat barleysugar it must first have become liquid from the moisture of the hive (and this is not a nice idea), or the bees must have had the extra work of carrying water to liquefy it, and all such extra work is labour thrown away. As far as the mere fact of feeding the plan has the merit of simplicity, but I fear that if it is a fact that bees can thrive upon barleysugar we shall shortly have a multiplicity of nostrums, such as sugarcandy, hardbake, toffee, bulls'-eyes, &c. A simple plan to be used with a minimum of trouble is doubtless a great thing, and any of these simple products would be preferable to the syrup recommended by Dr. Bevan in his treatise on the honey bee published in 1838, where on page 206 appears the following recipe, which seems to me to be a mild imitation of the contents of the witches' cauldron in Macbeth:—"A pound of coarse brown sugar and three-quarters of a pint of ale or sweetwort, boiled to the consistence of a syrup, to which should be added a teaspoonful of table salt." For the purpose of forming a closer imitation of honey, by increasing the pungency of the compound, Mr. Golding combines with his syrup a portion of wine and rum! This recipe follows:—"Sugar, 1lb.; honey, a quarter of a pound; salt, a teaspoonful; beer of moderate age, one pint. Boil for a minute, and as the syrup cools add to it half a glass of wine and a tablespoonful of rum!"

I should be glad to hear your comments on the subject; meanwhile I will state for the benefit of brother apiarians the composition of the syrup that I use, and which is, I am sure, grateful to the bees, as I have the greatest difficulty in excluding them from my laboratory, which is a dark room in a retired corner of the house, but into which they persistently find their way in

search of the glass measures which have been used in the manufacture. I use only filtered rain water, to every pint of which I add about three-quarters of a pound of loaf sugar. When dissolved I add to each two quarts of the syrup, 8 ozs. of barleysugar, and a large tablespoonful of glucose. The latter substance was originally added only for autumnal feeding, as it has the property of preventing sugar from crystallising, but of late years I have added it indiscriminately, as I believe it is very acceptable to the bees.—C. M. MAJOR.

[We hope other apiarians will send us a detail of their experience on this practice.—EDS.]

OUR LETTER BOX.

PIGEONS (*Fancier*).—If your neighbour shoots the Pigeons he can be made to pay their value by suing him in the County Court.

A KILKENNY BEE-KEEPER.—A correspondent wishes to write to him.

COMBS IN HIVES (*W. B. Tate*).—If the combs of the hives in which the bees died during the winter are sweet and were built last year by swarms, they will be of advantage to the swarms that may be put amongst them this season; but if they are the combs of stock hives last year swarms will do better in empty hives than amongst them. A few pounds of sugar given to swarms enable them to build combs rapidly on being hived.

TIME FOR ARTIFICIAL SWARMING (*Tom Tower*).—Your hive in ordinary weather will be ready for swarming about three weeks after the hive shall be filled or nearly filled with combs. If the combs which were cut out last year were outside the brood ones and not large pieces the hive may be ready to swarm sooner, but the usual time of swarming is three weeks after hives are full of combs and brood from side to side.

REMARKS.

1st.—Heavy showers in morning between 9 and 10 A.M.; dull and heavy all day, slight shower in afternoon, very close in evening with thunder and lightning, beautifully clear and bright night.

2nd.—Fine warm day, but rather cloudy.

3rd.—Fine day, though occasionally very overcast; very slight shower in evening.

4th.—Fine morning, rather cloudy afternoon.

5th.—Rather hazy morning, but bright afternoon and evening.

6th.—Somewhat dull and overcast day; shower in the evening about 10 A.M.

7th.—Fine bright morning, but clouds began to gather in the afternoon, and it looked rather threatening for some time. Rain began about 5.10, and in half an hour 0.85 had fallen; the rain then abated somewhat, but continued almost without intermission till 9 A.M. on the 8th, by which time the large amount of 1.705 had fallen.

The weather during the week was much warmer, the mean temperature being 5° above last week, and on the whole fine though rather cloudy and often close and oppressive.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 8.

TRADE is somewhat improved, but with increased supplies prices remain much the same with the exception of early fruit, which are generally lower.

A JAPANESE GARDEN—A SUGGESTION.

THROUGH a vista of years my mind is looking backward to a secluded spot enriched with many of Flora's richest treasures, and known by the somewhat vague appellation of "The American Garden," derived, no doubt, from the fact that the majority of its trees and shrubs were natives of America. Circular in outline it was bisected by a broad gravel path leading from and to other lawns and gardens, for it was situated in the very heart of shrubberies some forty acres in extent. Advantage had been taken of this division of the garden to impart a distinct appearance to each part, and yet this was so well done that there was an air of unity and connection in the whole of it. On one hand was a semicircular space rising gently from the path to its boundary, a wall, very high along the central part and sweeping downwards in bold curves to a pier at each end of the curved part of the semicircle. Magnificent old *Magnolia grandiflora*s had grown right up to the top of the wall, and most seasons produced hundreds of their large white flowers rich with a perfume that seemed to cloy the air with its sweetness. Many fine old climbers were there too; some of them I cannot recall to memory, but I shall never forget an immense spreading *Chimonanthus fragrans* which we used to think so wonderful with its winter crop of curious flowers, clusters sweet as a Hyacinth. A *Wistaria sinensis*, "old Harry's" pride, running all along the top of the wall and down among the other creepers; an *Abutilon striatum* that went on year after year bearing its curiously veined pendant bell-flowers, and passed through many winters in perfect immunity from frost; a *Solfaterre* Rose had grown over the top of the wall; and a *Bignonia radicans* twining along the top of one of the lower curves of the wall and bearing aloft clusters of its bold orange-coloured trumpet flowers, were some of the favourites which still haunt my memory.

Along the foot of the wall ran a border, and the remainder of the garden was laid out in beds and grass walks. In the beds were all sorts of rarities—*Calycanthus floridus*, with its curious aromatic brown flowers; bright pink patches of *Erica carnea*, fragrant *Daphnes*—it was here that I first learned to know and value the sweet green-flowered *D. pontica*, and the equally fragrant pink-flowered trailer *D. cneorum*—*Azaleas*, *Ledums*, *Roses*, *Yuccas*, all mingled with perennial flowers and bulbs.

The other half of the garden was a lawn shut in by a belt of *Rhododendrons* and other shrubs, with sheltering clumps of lofty *Fir* trees, mingled with *Oaks* behind. About the lawn was dispersed a collection of deciduous *Magnolias* and a *Salisburia adiantifolia*, all of them so large as even then to be regarded as trees. Some of these *Magnolias* remain still; they have braved the storms of probably fifty winters, and are 40 feet high. All the other trees, &c., referred to have been swept away by the hands of "improvers." My object in dwelling upon this old garden is not, however, to indulge in vain regrets, but to convey to the reader some faint idea of its form and beauty

as an inducement to act upon the suggestion now to be made.

Considering the rich store of the Japanese flora now in our hands a novel feature might be added to all gardens affording the requisite space by making a Japanese garden—that is to say, a garden containing only plants and trees introduced from Japan. That such a garden would be attractive there can be no doubt, for everything brought from that country has peculiar points of beauty either in habit of growth, form, or colour of foliage or blossom. Take, for example, the Conifers: what can be more curious and ornamental in their way than the *Retinosporas*? Then there is the Umbrella Pine (*Sciadopitys verticillata*), which I have heard termed the most ornamental of all Pinuses; certainly it presents a very distinct and striking appearance in such examples as have come under my notice. *Thuja borealis* is one of our very best Conifers, and *T. dolabrata* is full of promise. There are also four or five varieties of *Abies*—notably *A. Tsuga Hanburyana*, the Japanese Hemlock Spruce; and who does not admire *Cryptomeria elegans*? We have also *C. japonica*, *Juniperus japonica*, a *Larch* (*Larix leptolepis*), a *Cephalotaxus*, the more common but very peculiar *Taxus adpressa*, *Thuja falcata Standishii*, and the well-known *Salisburia adiantifolia*.

Among shrubs and trees what a host of beauties do we find! One is quite at a loss which to select—perhaps the Maples should come first, as they are just now so beautiful in their vernal clothing of fresh young foliage. The one which I regard as most ornamental bears the wonderful name of *Acer polymorphum atro-purpureum*. One planted three years ago has made annual growths of about a foot; its elegant palmate foliage is now of a rich crimson colour tinged with purple, and nothing can be more charming than the effect of sunlight upon the brilliant mass of foliage. The others, all worthy of a place, are *A. polymorphum*, *A. p. roseum marginatum*, *A. p. sanguineum*, *A. p. dissectum*, *A. p. palmatifidum*, and *A. p. reticulatum*.

With the dwarf lovely white-flowered *Deutzia gracilis* all are familiar, and there are some *Hydrangeas*, of which perhaps *Otoko* with its immense heads of pale rosy flowers, and *hortensis variegata*, may be known pretty generally; but the charming *H. paniculata grandiflora*, with white pink-blotched flowers, is not so well known. Then there is the early-flowering *Azalea mollis*, with some twenty varieties; the pretty pink evergreen *Azalea amena*. A *Rose* which is so very Japanese in being different to all other *Roses* is named *Rosa rugosa Regeliana*. The shoots are thickly set with small spines, and have a dense clothing of deep green foliage, bearing numerous flowers, which are single in large clusters of a bright crimson colour, and are followed by a crop of bright red berries. I first saw it growing in Messrs. Wood's nursery near Uckfield, and I regard it as an ornamental shrub of much beauty. We have also a Japanese *Laurustinus* (*Viburnum Sieboldii*) which I have planted for the sake of its bold glossy foliage; *Skimmia japonica*, and its varieties fragrans, *laurifolia*, *oblata*, and *ovata*; *Raphiolepis ovata*, an evergreen with spikes of white flowers; the popular and useful *Ligustrum japonicum*, *L. coriaceum*, valuable for clothing pillars with

its stout glossy foliage, and *L. glabrum aureo-variegatum*; the singular *Elaeagnus longipes*, said to be very ornamental, with orange berries, but as I only planted it last season I cannot say more than it has a curious appearance. Then come all the *Aucubas*, *Mahonia japonica*, *Ilex japonica* and its three varieties; a *Daphne*, a *Bamboo*, a *Palm* (*Chamaerops Fortunei*) which has proved quite hardy in the south, growing so freely that the noble specimen at Lamorran is upwards of 15 feet high; an *Elm* (*Ulmus Kaki*), an *Oak* (*Quercus glabra*), the evergreen *Aralia japonica*, with large handsome foliage, and which has already attained the dimensions of a dwarf tree in Cornwall, and many others which I need not enumerate, enough having been named for my present object.

For walls we have several *Clematises*, the familiar *Cydonia japonica* with its rich red flowers; the best of all Honeysuckles, *Lonicera flexuosa*; the pretty variegated *L. aureo-reticulata*; the evergreen *Photinias*, *Ampelopsis japonica*, the curious *Akebia quinata*, often termed a greenhouse climber, but quite hardy in the south; *Cissus japonica*, and *Wistaria macrobotrys*.

For borders plenty of *Lilies* of the auratum and tigrinum species, the scarlet-flowered *Lychnis speciosa*, *Iris Kämpferi*, *Eulalia japonica* for both borders and lawn clumps, with stems 5 feet high, slender variegated foliage, and panicles of pink flowers. The stately *Bocconia japonica* is also suitable for either purpose. *Primula japonica* is now well known, and one might continue the list with the yellow *Hemerocallis*, *Rodgersia*, *Polygonatum*, &c., but I refrain, and conclude with the wish that cause has been shown why more particular attention should be given to the collection and culture of what, may fairly be termed Japanese beauties.—EDW. LUCKHURST.

VEGETABLE CULTURE.

CHAP. XVIII.—VEGETABLE MARROWS.

THE Vegetable Marrow is a native of India. It is very useful and not difficult to cultivate. Being a tender annual it can only be grown in the open air throughout the best part of the summer and autumn. As a rule it may be turned out with bedding plants about the third week in May, and it will remain healthy in autumn until about the time the Dahlias are cut down by the frost. In the north we have never found it safe to plant out Marrows until the first week in June, but we have planted them two weeks earlier than this in the south. The plants should not be less than a foot in height when they are planted out, and if they are longer all the better. They are very easily raised from seed, which should be sown about a month before the plants are wanted for planting out. The soil used should be very rich. A mixture of half horse dung and half loam suits well in which to sow the seed, which may either be sown singly in 3-inch or 4-inch pots, or five or six seeds may be placed in a larger pot. When placed in a bottom heat of about 75° it germinates quickly, but at the same time healthy young plants are soon formed in any ordinary house or even cold frame during April and May. The plants from seed sown singly in 3-inch pots should be shifted into 8-inch pots as soon as they are 8 or 10 inches high. Those sown together in one pot must be potted off and be treated in the same way. Where there is no convenience for raising plants under glass the seed will germinate freely if sown in the open soil after the middle of May. When raised under cover the plants should always be kept close to the glass, as it spoils them to become drawn up weakly. Ten or twelve days before planting out they should be freely exposed to the air night and day, and if possible they should be protected with hand-lights for a fortnight after they are planted out, but these are not indispensable.

Those having large dung beds generally plant their Marrows out on them, and they answer the purpose capably. Where there are no dung heaps a quantity of newly cut grass litter, old Broccoli leaves and stumps, and fermenting material of any description may be thrown together, mixed and made into a firm heap on which to grow them. The heat which rises from this pushes the plants on rapidly. Heaps of this kind should be covered a foot in depth with rich soil in which the plants must be planted. They may also be planted in good soil without any heat underneath, or on the top of old hotbeds which may have been used for propagation or for the raising of plants of early vegetables in spring. When once they have begun growing they go along rapidly, and the points should be taken out of all the shoots that are inclined to straggle. All small shoots with no fruit on them should also be removed. This is about all the training they require. In dry weather

they should be copiously watered. When the fruit is shy in setting it is well to impregnate the female blooms with pollen from the male flowers. All fruit should be cut before it assumes a yellow ripe-looking appearance, as the supply can only be kept up by giving the small fruits a fair chance at first. Vegetable Marrows are much grown in some districts by cottagers for exhibition; and it is gratifying to observe that some seedsmen are inclined to encourage this, as Messrs. J. C. Wheeler & Sons of Gloucester not only supply Marrow seed gratuitously to cottager exhibitors at our local show, but offer handsome prizes for the produce as well.

Long White and Moore's Vegetable Cream are two of the best to grow for all purposes. The fruit of the Custard Marrow is prized at the table for its peculiar shape.—A KITCHEN GARDENER.

CULTURE OF DOUBLE PRIMULAS.

FEW plants are more useful than double Primulas, and more especially as they bloom during the duller part of the year, and no plants can be more valuable for cutting. The rosette-like flowers not only last for a lengthened period whilst in a cut state, but they "make-up" well in bouquets and associate well in vases with other flowers. They are consequently much sought after by bouquetists and decorative florists. A great advance has of late years been effected in the raising of new varieties, and the flowers are larger and the colours more varied than formerly.

The best of the double varieties can only be propagated by cuttings. Some growers find some difficulty in striking the cuttings, or these plants would be more largely grown. It is not advisable to divide the plants every year if the cultivator's aim is to have large specimens, but it is desirable to strike cuttings every year so as to provide a stock of healthy young plants. The cuttings should be selected from plants that have made long growths and have become "leggy." After they have ceased blooming and have again started freely into growth the side shoots or the divisions should be taken off with a sharp knife; a heel should be secured to each cutting. Place them singly in small 60-sized pots in some light sandy soil, securing the cuttings if they are large to small sticks to keep them firm. Plunge the pots in a brisk heat, but do not keep the soil or atmosphere too moist, or the cuttings will damp off. When they are rooted remove them from the propagating pit, and when well established repot into large 60-pots in a compost of two parts of light turfy loam, one of leaf soil, and a little very much decayed cow dung and silver sand. Care must be taken to have the pots well drained, as the plants very much dislike stagnation at the root, and when potting it is necessary to keep the collar of the plant well up. After potting keep them in an intermediate temperature with an abundance of air circulating about them. When they are well rooted inure them to a cooler atmosphere (a cold frame will suit them admirably), and by the end of July they will be ready for shifting into a size larger pot. About the end of August they must be removed to a warm and airy position in an intermediate house, where they will bloom freely. Particular care must be exercised in the watering during the winter months, as the roots are very tender. After they have finished blooming, those that will not be required for propagating purposes should be repotted into larger pots, keeping them rather close and warm until they are established, when more air must be given and the plants be treated as during the preceding season.—A SOUTHERN GROWER.

SYRINGING VINES.

I AM more than ever a convert to the non-syringing process, at all events where Vines are planted outside; but for Vines planted inside it is possible that syringing may be an advantage, but I doubt it. I have just been reading an article on Vines. It says, "Syringe to prevent red spider;" it should have been, "Syringe to produce flabby growth, and then red spider will come." I have always found unsyringed Vines to have foliage of a stronger texture and more free from red spider than Vines grown in much heat and freely syringed. I am acquainted with Vines which have been excessively syringed for twenty years, and the crops have always been miserable. I am firmly convinced that the undue use of the syringe has greatly contributed to this unfortunate result. The more experience I gain the more strongly I am convinced that syringing is one of the greatest mistakes in Grape-growing. The Vines under my

charge have been bearing heavily for a quarter of a century, and this year the crop is finer than ever. They are never syringed.—W. W. B.

EXPERIMENTS IN ROSE CULTURE.

YOUR readers might perchance be interested in a brief account of a few experiments I have carried out in the cultivation of several classes of plants. My object in view was to grow plants on scientific principles, so as to obtain if possible perfect development. The first essential was the provision of the requisite elements for the construction of the plant, resting on the theory of Liebig that the neutral salts must be provided for the roots, and that the carbon required would be obtained from the air by the action of light.

My first process on the Rose was by incineration and analysis to ascertain the neutral salts and their relative amounts. The results on practical application were various—great stimulation in certain cases, but in most gradual sickening and death of the plant. A careful examination of the soil showed that with the addition of my neutral salts to those already in the earth, the ratio of certain elements had been given too great a predominance, and had acted as a poison. The conclusion I arrived at being that the theory was sound; but as it required a quantitative analysis of each spadeful of earth, it was practically useless for my greenhouse purpose.

On analysing the sap of flowering Wheat I failed to detect phosphate of lime, and yet I knew it was there, as bread will support life, which it could not in its absence, as in Potatoes, on which a horse dies in about eight days, whilst he will fatten if chopped straw be added.

In the seed of the Rose I found a complete store of the neutral salts obtained from the ash of the stem. It was, therefore, manifest that the blossom acted under the sun's rays as a chemical battery for eliminating from the sap the neutral salts to be stored up as the pabulum of the future plant. Acting on this, I collected the Roses as they faded in the garden, taking them off to the second leaf where the first bud is found in its axil, and packed the Roses in a cask with the seed pod and first leaf as above described, and after a few months when this was decayed I rubbed up this rose-leaf mould with various sorts of loams and peats, in the proportion of nearly one-fourth of the former to three-fourths of the latter. I then planted therein *Devoniensis* of the same size and age, all cuttings of the previous year. Their growth and health were marvellous, and the number and size of the blossoms exceeding everything I had ever seen before; and what struck me as being peculiar was, that plants grown in loam from Epping, loam from Weybridge, loam from Coombe Wood, or peat from Wimbledon manifested no diversity, excepting that in the last (peat) the leaves were slightly purple and not quite so large, though the wood was fully as strong.

I also found that the Roses (in pots of course) retained their vigour and blooming power, and resisted the cold of winter (for I had no heat) with wonderful impunity, by giving them a top-dressing of the powdered rose-leaf earth with about a quarter of a pound of iron filings. These, of course, oxidised; and as I used rain water containing ammonia, and sometimes guano water very weak, the ammonia was fixed by the oxide of iron, forming ammoniate of iron—a soluble salt, and was therefore the means of conveying to the roots the nitrogenised compounds as well as the iron that is an element in almost all plants.—AMATEUR.

P.S.—I was told by a friend the other day that there is nothing new under the sun, for in the first book printed in England on horticulture (I cannot remember the title), it says "If you want your Roses to grow fine and be extra sweet, grow them always in an old Onion bed."

FRUIT PROSPECTS.

THE Dutch do not say a man is a bankrupt, but that he did not "keep accounts" or "take stock." Let me take stock of my fruit prospects.

Small Fruits.—Currants, Gooseberries, Raspberries, Strawberries are uninjured, and will be a very good crop. Cherries.—Morellos are a heavy crop, both the old sort and Morello de Chameux, dear kind Mr. Rivers' present. Dessert Cherries.—These are in fine crop and apparently safe: Bigarreau Napoléon, Empress Eugénie (two trees), Late Black Bigarreau, Brant, and Governor Wood.

Pears.—Beurré Hardy, Dr. Trousseau, Doyenné du Comice,

Beurré Clairgeau, Duchesse d'Angoulême (splendidly cropped on the Pear stock, the gift of Mr. C. Turner), Louise Bonne of Jersey, Poire Peach, Beurré d'Amanlis, Beurré Mauxion, Beurré Diel, (two trees), Beurré Bachelier, and two culinary trees not named, are in good crop and apparently safe, but till July (dropping time) we cannot decide the fate of Apples and Pears.

Apples are in fine bloom, but not forward enough to decide upon them.

Plums.—Belle d'Orleans, Rivers' No. 4, figured in the "Florist," Mitchelson's, Belle de Septembre, and Diamond are in good crop and apparently safe. Of Pears, Plums, and Cherries there are a good many failures.

Peaches and Nectarines.—These are well cropped under glass—namely, Royal George, Rivers' Early Silver, Barrington (two), Grosse Mignonne, Early Alfred, Early Louise, and the two Nectarines Prince of Wales and Violette Hâtive. Early Louise in my judgment is the best very early Peach, and the Royal George for indoors and out-of-doors work is the best Peach to have. The following are in good crop and apparently safe. South aspect—Peaches.—Royal George (three), Early York, Bellegarde, Nectarine Peach, Early Ascot, Early Alfred, Lord Palmerston, Barrington, and Violette Hâtive Nectarine. East aspect—Royal George (two) and Bellegarde. West aspect—Noblesse, Royal George, Dr. Hogg, and Rivers' Orange Nectarine. The east walls were most cut up. Had it not been for the "royal sail" coping little could have been saved. I observed that during the severe frosts the blossoms kept perfectly fresh and set their fruit most close under the dark shade of the sail. The pistil (female) is an unit, and if injured before impregnation there can be no fruit; also if the stamens (male organs) are injured there can be no fruit. Some of my sheets are ringed, but the last "royal sails" sent have an eye let into the sheets and tied by thick rope. We like these better than the ringed sheets, because the winds are so violent that the rings saw the sheets. I put on the "sails" March 10th and removed them April 29th. Many trees of all kinds have lost their crop, and some have a few fruits. I shall, notwithstanding droppings, have more fruit than I shall know how to do with.—W. F. RADCLIFFE.

THE NATIONAL AURICULA SOCIETY'S SHOW.

I SUBMIT myself unaffectedly to the strictures of your correspondent "VISITOR" and your remarks in the report of the National Auricula Show as set out in your last week's number, albeit somewhat exaggerated as to fact. I trust, however, you will allow me to say in explanation the evil arose rather from misfortune than fault.

Partially recovered only from the prostration due to long-continued acute bronchitis I lacked strength alike for the speech and action requisite for effective direction or leadership, and in this unhappy predicament had to contend with unusual difficulties. First my friend and colleague, Mr. Charles Turner of the Royal Nursery, Slough, was unable to be present from severe indisposition, and therefore his great aid was wanting. Next three exhibitors from the north from whom a considerable contribution was expected failed to put in an appearance, thus making the final arrangement and distribution of the several classes up to the time the Judges should have commenced their labours an impossibility. And finally our northern friends, Messrs. Horner, Barlow, and Simonite, who contributed so effectively to the importance of the Exhibition, and whose plants required by far the largest amount of preparation, were so worn down by thirteen hours of railway travel during the previous day and night that it was hopeless to attempt to hurry them in those needful preparations; and I presume to think, had I exercised the power vested in me of rejecting contributions not ready at the hour named—10 A.M., I should have taken a course fatal to future exhibitions of the Society, and such as would have produced an unanimous feeling of indignation in every person interested.

"VISITOR" and your reporter may be assured the matter of their complaint will not be treated with indifference; and the Judges who suffered—the Rev. Mr. Tymons and Mr. Tandy—who had come from so far to render us such signal aid, will, I trust, allow me to assure them they shall not in the future, if they will again serve us, be exposed to such annoyance.

To "EMBRYO" I would simply say he does the Committee only justice when he assumes they desire to develop and encourage new exhibitors; and if he will put himself in communication with me, though I cannot think his proposal to

create a class for exhibitors who have never before won prizes at all desirable or advantageous, yet I will give him proof of this desire on the part of the Committee, and I trust the arrangement of prizes in future years will satisfy and gratify every legitimate aspiration.—E. S. DODWELL, *Secretary*.

A RUN THROUGH CHATSWORTH GARDENS.

BEING rather unwell I went into Derbyshire lately to have a change of atmosphere and a short season of rest, and there finding myself within ten miles of Chatsworth I went one morning last week to see its gardens and my friend Mr. Speed, who manages them. I was greatly pleased with much that I saw. "The Palace of the Peak" appeared to my eye larger and more stately than it did on former visits, and the gardens seemed grander and broader in their features than they ever appeared to my eye before. Finding Mr. Speed near the kitchen gardens he took us through them first. What ranges of forcing houses we walked through! Eighteen vineries, a number of Peach houses, &c. I will not attempt here to review all that met my eye in the gardens at Chatsworth, for I took no notes and cannot remember the half, and therefore will confine my remarks to a few things that struck me in following Mr. Speed through his hothouses.

Let us look at the vineries first. Two of them are full of Vines in pots, eighty in each house, three bunches on each Vine, and some of the bunches I was told would weigh from 2 to 3 lbs. Capital practice this for early work. These Vines are grown from eyes every year and yield their crops in May, and thus prevent the pressure being put on the early houses before their fruit is fully ripe. The fruit in the first house of Hamburgs seemed quite as ripe as the fruit on the Vines in pots; and the history of this house as given by Mr. Speed is interesting. The Grapes in it last year shrank very much, and the Vines were considered worthless—mere cumberers of the ground. There was no risk in trying an experiment with them. Mr. Speed knew that there was food enough in the border, but fancied it was locked up in some way and might be liberated. He thought of bark-bound trees and men with sluggish livers. After the Grapes were cut last year he dusted the borders thickly with caustic lime; in fact, gave them a good coat, and forked it in during the winter. This coating of lime did all—perhaps a little more—than he anticipated, for the leaves of the Vines became healthy and vigorous as soon as the lime liberated the food of the borders. And what is the result this year? A house of fruit without a shanked berry; both bunches and berries of moderate size, and well coloured; and the shoots of this year are full of vigour, carrying great leaves blooming with health. The experiment was thoughtfully planned, and well and satisfactorily carried into execution. The Vines have been restored to health at very little expense of either money or labour.

I was so pleased with many things in the vineries at Chatsworth that I advised Mr. Speed to write a small treatise on Vine-growing, and thus give the public the benefit of his experience, now pretty ripe and extensive. In growing Grapes his aim is to have every bunch, and every berry of every bunch, perfect and well finished. The bunches are not only well thinned, but some of the larger are lessened in size with a view to have large berries, or excellence of quality. His borders are never dug, not even pointed with a fork, but are well manured by a three-course rotation of applications—that is to say, they have a different kind of manure this year from what they had last. First year they have stable or cow manure, second year bone dust, third year potash in some form or another, and soot every year without limit. I saw the men making some of the borders black with soot while I was walking through the gardens. Mr. Speed feeds his Vines well, and Mr. Thomson of Clovenfords spreads £100 worth of manure on his borders every year. All people know that great fat bullocks and horses have been well fed, and that without good feeding no such animals can be reared or seen anywhere. The grand Grapes which often meet the eye now-a-days are the outcome of rich borders and good management. Grape-growers have, as a body, been rather slow to estimate good stable manure at its proper value.

Another point in Mr. Speed's management is worth notice. The main rods of his Vines are 3 feet from the glass. Our great teachers on Grape-growing tell us to keep our training wires 16 inches from the glass for securing the rods and shoots of the Vines. Now our friend at Chatsworth, who thinks for himself, makes an amendment on this rule and puts it into

practice with great advantage every way. He lets his rods hang 18 inches below the wires, say nearly 3 feet from the glass. Well, the shoots grow upwards towards the light, and do not get broken against the glass or by the hand of man in trying to keep them from it. The shoots are tied to the wires, and some of them carry and ripen their bunches above the rods, so that on entering a vinery one does not see all the bunches hanging below the rods in orthodox fashion. We have to look amongst the leaves for the fruit. I saw the same mode practised at Temple Gardens near Manchester thirty years ago, and have ever since considered it the best and easiest way of training Vines. By this mode of training Mr. Speed exposes more leaves to the light, and therefore could get more fruit if he wanted it. In the last range of vineries we entered I noticed a Vine showing large bunches, which he said was his seedling, the result of a cross between the Alicante and Muscat of Alexandria. So far as size of bunch goes it is very promising, and Mr. Speed speaks well of its flavour. It is not yet named or put before the public.

I must not forget the Fig house and its crop of fruit, for I never saw Figs growing in such profusion or trees in such robust health. The fruit was as thickly on the shoots as Gooseberries are on theirs, and swelling fast. "Well, Speed, I never saw any gardener that can come near you in growing Figs! Never witnessed success equal to this! How do you manage it?" Answer: "I make my borders like Vine borders, and never prune or touch with a knife either root or branch. Sometimes I bend the shoots so as to fill open places and thus get the light, but never use the knife to shorten the shoots; but probably I owe my success to the fact that I rest my trees in winter. While other growers are ripening a third crop of fruit my trees are put to rest. I am satisfied with two good crops of fruit." Mr. Speed attaches great importance to his practice of letting his plants have a good rest, or in other words as long a winter as possible.

The Cape Gooseberry house always interests me. Last week it was full of fruit from end to end, and from bottom to top. It is hardly ever without a dish of Gooseberries. The Cape Gooseberry plants if treated like a Tomato will grow and bear fruit out of doors. In a span-roofed Melon house I noticed an experiment in progress with his Melon plants. Some twenty plants are planted in pure clay, and the rest, perhaps five times that number, are planted in good maiden loam. Most of the plants were beginning to show fruit. No difference could be seen in the plants. Those in clay were growing and showing as well as those in maiden soil, and the clay was well filled with roots. No experiment could be made in a fairer manner than the one I am now noticing, and I shall be concerned to know if the clay produce fruit equal to the loam.

In going through the plant departments at Chatsworth, the Orchid houses and large conservatory, I found much to admire and think about—plants in great variety, sometimes grouped in kinds and sometimes in mixtures, and all in the floral world of the Peak Palace indicating as much skill and care in their culture as we found in the fruit world below.

After dining with Mrs. Speed in the palace of the late Sir J. Paxton, probably the finest and most costly gardener's house in the world, we mounted our trap and left Chatsworth by the principal entrance, thinking that the noble owner of this princely place was fortunate in having so able and enthusiastic a gardener as Mr. Speed, and that Mr. Speed was highly favoured in having the Duke of Devonshire for his employer.—A. PETTIGREW.

TROPÆOLUM BALL OF FIRE.

A MOST useful and brilliant flower is this variety of *Tropæolum*. It is easy of cultivation, simply and easily trained, effective as a trailing plant, and it is especially adapted for training on the roofs of low-roofed houses, where the flowers are easily reached when wanted. It is useful also in the conservatory, and I hope soon to see this plant in general use. For a supply of brilliant scarlet flowers during the autumn, winter, and spring months I am not acquainted with many plants so serviceable as this is. It also makes a fine decorative plant on trellises of any shape that may be found expedient.

I lately saw in Messrs. Osborn & Sons' Nurseries, Fulham, a proof of the usefulness of this plant. They have it trained on the top of a shallow span-roofed cool house, where it is growing in luxuriance, and blooming in profusion. I was informed flowers had been cut from the plants for many months past, and the plants look likely to continue flowering for

months to come. These plants were growing in 24-sized pots only.

The soil requisite for growing this *Tropaeolum* is simple enough; an admixture of three parts of good friable loam, half a part of leaf soil, and half a part of good decayed cow manure with plenty of silver or river sand suits the plants admirably. Water must be administered judiciously, or rotting-off at the collar may be the issue, especially in the winter months; but as the season advances a good supply of water is necessary, and occasionally guano water may be used with advantage. The propagation of this plant calls for no comment, as cuttings may at all seasons be struck under the treatment given to the commonest bedding plant.—J. P.

AURICULA SHOWING.

I SHOULD not have been surprised had "D., Deal," objected to separate classes being made for new exhibitors, but I did not suspect that he would have opposed the new growers mixing Alpines with show varieties.

The reason that "D., Deal," advances against the admission of Alpines would exclude them from the schedule altogether. If Alpines should not be admitted because "anybody can grow and bloom them," why have classes for them at all? or indeed why have a Pelargonium Society and offer prizes for zonal Pelargoniums? or why have a Rose Society and offer prizes for Hybrid Perpetual Roses? If "anybody" can grow Alpine Auriculas anybody can also grow Roses and Pelargoniums. Admitting that to be the case, we must also admit that "growing" is a relative term. Anybody may grow them, but does or can everybody grow them well? That is the real point. The object of exhibitions is to promote excellence of culture, and surely Alpine Auriculas are as worth growing well as are other flowers.

Assuming that the National Auricula Society desires to gain as great an increase as possible in the number of exhibitors and subscribers it seems reasonable to offer every possible encouragement to new growers, and to allow them at least the same privilege that the old growers enjoy of mixing, if they choose, Alpines and show varieties in one or two small classes. By no other means can new exhibitors be secured so well, for the sufficient reason that the majority commence with Alpines on account of the show varieties being difficult to obtain.

The suggestions made will no doubt be considered by the Committee of the National Auricula Society, a body of cultivators who can be well trusted to arrive at a right decision in the matter.—EMBRYO.

VICTORIA PARK IN MAY.

FROM time to time allusion has been made in the horticultural press to the attractiveness of the various London parks, and especially to the excellence of the summer and autumn decoration of the flower beds and borders. Nowhere in Her Majesty's dominions can better work be found than that alluded to, and probably no work of the Government meets with more unqualified approval of British taxpayers than that accomplished in such parks as Victoria, Hyde, and Battersea. While the summer beauty of these parks is admitted to be of a high order, they are worthy of equally honourable mention for their attractiveness in spring. If in September they are gorgeous, in May they are lovely. In late summer their beauty is of an artistic order; in early summer natural charms predominate.

Victoria Park is now peculiarly enjoyable. The grand masses of foliage and its varied and refreshing tints while yet undefiled by London smoke cannot fail to command the high appreciation of all visitors. Flower beds may be criticised and certain arrangements of colours and combinations of plants may be objected to according to the effects they produce on different minds, but the natural beauty of trees when it is permitted to become fully developed is beyond criticism. Occasionally adverse weather, but more frequently injudicious planting and grouping of trees, mar their beauty; but the weather this spring has been unusually salubrious, and the planting of the trees in this Park has been done with much taste, and the result is that the Park cannot at any period of the year be more really beautiful, more thoroughly enjoyable than it is now.

Neither is the beauty at all monotonous; on the contrary, it is most varied. If you want severe and stately beauty you have it in the imposing avenues of Limes and Elms. The

trees themselves—the play of light and shade dancing amidst the foliage, and the ground beneath dappled with slanting shadows, are all elements of beauty which cannot be passed unobserved during the spring time of the year. "Unter den Lindens" is a favourite resort of the east-enders who repose by thousands in the seats provided for them. These fine young avenues are principal feature of this Park, and the manner in which they are appreciated suggests that shady promenades are indispensable to the full enjoyment of public parks and gardens.

Do you want something less formal—free and rugged beauty? and you find it in the curving walk at the south of the upper lake. Boldness of conception, admirable taste, and skilful execution are reflected in this division of the Park. On the one hand abrupt rising mounds surmounted with choice forest and deciduous flowering trees produce at this period of the year an effect with which carpet beds in summer are puny by comparison. On the slopes of these bold promontories the double-blossomed Cherries have lately been masses of purity, and now the Thorns, in double and single, pink and white, are carrying on the floral display. The *Crataegus* are very numerous and fine. A tree of *C. precox*, the Glastonbury Thorn, is now in full beauty, and there are many attractive specimens of *C. pyrifolia*; *C. tanacetifolia* and others are equally attractive. These trees and golden Laburnums, and dense masses of Lilacs interspersed with the deciduous trees, noble specimens of Hollies and other evergreens, render the mounds of flowers and foliage singularly imposing. The banks are broken by nooks and vistas, and their sides are relieved by groups of Yuccas, *Y. recurva* being largely grown and produces an elegant and distinguished effect. Alpine mounds richly clothed in the most natural manner with Sedums, Rock Roses, Ivy, &c., impart agreeable variety to the surrounding wealth of foliage and flowers. On the other hand, the water is seen through curving vistas. The weeping trees on its margin, Kilmarnock Willows, Birches, Poplars, &c., are now in their early summer freshness. The Weeping Aspen (*Populus tremula pendula*) is singularly graceful now that its ever-moving foliage reflects the light from its glossy leaves. It is one of the most elegant of weeping trees, but to be seen to advantage in the London parks it must be seen in the spring. The several islands are similarly seen to better advantage now than later in the summer; for not only is the foliage fresh, clean, and glossy at the present time, but it is not sufficiently dense to prevent the natural herbage and wild flowers being seen with which the islands abound. The "water scenes" in this Park are extremely picturesque. The rich masses of overhanging foliage of various hues contribute greatly to the attractive appearance of the lakes. One of the most imposing of the overhanging trees is the Weeping Wych Elm (*Ulmus montana rugosa pendula*), its large branches of bold foliage spreading almost horizontally for several feet across the water.

Whatever force there may be in the objections that are sometimes heard as to the "chilling artificiality" of the London parks when the carpet bedding is at "its height," such objections cannot apply now, for natural beauty reigns supreme during the months of May and June. During the present year the tree-beauty of the parks is especially striking, for never before has the foliage expanded more freely and the flowers opened more profusely and kindly.

There is also at Victoria Park flower-beauty of a lowlier form than that pertaining to the trees. The mile-long semi-wild herbaceous border has for a length of time been gay with spring-flowering bulbs, and will continue attractive throughout the season as the different hardy plants unfold their flowers. At the present time the most conspicuous flowers in this border are the snow-like cushions, nearly as large as cart wheels, of Iberises. These telling masses are 5 and 6 yards apart, and equally effective behind them are bold clumps of the large blue German Iris, which is one of the most valuable of shrubby plants for town and country gardens. Exceedingly cheerful now are large clumps of *Scilla campanulata* and the white double Tulip *La Candeur*. Wallflowers impart perfume, and are this year fairly good: usually they perish during the winter and are not reliable London park plants. Neither can Sweet Williams be grown in any satisfactory manner, nor Phloxes. It is sufficient, however, to observe that whatever can be grown is grown; for although "bedding-out" is done so well the Superintendent of this Park is an ardent lover of hardy plants and florists' flowers, and does all that he can to promote their culture.

The Tulip beds in the principal flower garden have been gorgeous, but are now fading. Only three varieties are grown in quantity—namely, Yellow Prince, Rex Rubrorum, and La Candeur : those are found to succeed the best and to give the greatest amount of satisfaction. The beds will shortly be occupied with other flowers which are now in the preparing grounds. In this department men are as busy as bees striking cuttings, potting, boxing, cleaning, and sheltering the quarter of a million of plants that are required for the season's display. A finer lot of plants cannot be wished for than those now nearly ready for the beds. Plant-making, and, indeed, flower-pot making, are still going on and will continue for some time. The pots are made of loam, cow dung, and leaf soil ; in fact, rich potting mixture moistened like mortar. A man with a tin mould makes eight hundred pots per day ; forty thousand of these pots made this spring are now in use. If made in the morning and a fine day follows the pots are ready for use in the afternoon. These pots are planted in the beds, turn soft by the moisture of the soil, and the roots protrude through their sides ; in fact the feeders are through in all directions before the planting is done. Thus the plants are supported and the beds are enriched at the same time. Nearly all kinds of plants thrive in them as well as in properly burnt pots from the potteries ; the exceptions are *Alternantheras*. These plants do not "take to" the "mud pots," but all other small bedding plants grow in them luxuriantly.

Every department of this diversified Park testifies that it is in excellent keeping, and an inspection of it at this period of the year is quite as pleasurable and equally instructive as a visit during August or September.—VISITOR.

A PLEA FOR AMARYLLISES.

UNDER the above heading Mr. Abbey gives an outline of how he grows the *Hippeastrum*. The necessity of a "plea" is in itself evidence that objections and difficulties exist as to the cultivation of these plants, for everyone is ready to admit that few flowers are more beautiful or capable of affording more interest in their management. How is it, then, that they are so seldom met with in greenhouses? Amongst my numerous acquaintances I now know but one who has not discarded the attempt to grow them. The reasons are very obvious : first their costliness, and second the difficulty in getting any information or description of the best sorts to grow. The fact is they have been crossed in every conceivable direction, and for one good variety raised hundreds of worthless seedlings have been produced and, unfortunately, not destroyed, and these form the bulk of the bulbs offered for sale, care being taken to omit all description of the flowers, save of a few old-established species, in the annual catalogues. If anyone, therefore, takes the trouble, as I have done, to send to the first houses for six or eight dozen bulbs and grow them on for a year or two till they come into bloom he will find that not one in ten will repay the trouble of growing, and that he has bought disappointment at a great cost ; whereas, had he in the first instance given several guineas for a single bulb he might have been charmed with a fine variety for years. But such costly bulbs few amateurs are willing to purchase when making their first essay, and the memory of previous disappointment is tenacious and difficult to eradicate. However, of less costly bulbs I can strongly recommend beginners to obtain the following, which will flower well in a cool greenhouse under proper treatment :—Osborn's Defiance, marginatum venustum, pardina, vittata Harrisonii, v. superba, and reticulata major. These can be purchased for about half a guinea each—i.e., flowering bulbs, and will well repay culture provided only they be procured free from thrips and mealy bug.

Your correspondent is quite correct as to the folly of keeping them too dry at any time. I know of nothing that requires drying off, and since I have taken to deluging even *Gloxinias* I have lost none, and as early as March I had in a cool house forty or fifty plants sufficiently advanced to enable me to make cuttings for succession plants for flowering in August and September, and if the season be then mild they will continue in bloom almost to Christmas, as was the case last year.—AMATEUR.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE ordinary monthly meeting of this Association was held on the 7th inst. in The Hall, 5, St. Andrew Square, Edinburgh. There were about a hundred members present, the President in the chair. Twenty-three new members were nominated for admission.

After the usual routine business Mr. John Methven read a paper on a holiday ramble among the Alps, describing the grand and varied scenery of the country, and naming the various plants found in the different vegetable zones. He also told the members of the many beautiful Alpines that grew and flourished there unheeded. Mr. B. Lindsay followed with a paper on their cultivation. He went over the principal cultural points that ensured success, and exhibited some thirty specimens of the most beautiful and rare gems of the long list of Alpines. A short discussion followed the reading of the papers. Thereafter a paper was read from Mr. John Webster, Gordon Castle, on Peach culture in the open air in Scotland. After adverting to the uncertainty that attended a fruit crop in North Britain the writer of the paper detailed his own experience in the culture of the Peach at Gordon Castle. He formed a border along a south wall to the depth of 8 feet with 16 inches of drainage, leaving only 20 inches for the

Fig. 56.—*Erica propendens* (see page 376).

roots to roam in. This plan gave the roots a large share of solar heat, and proved eminently successful. The discussion which followed brought out the truth of Mr. Webster's observations, several members alluding to the high culture of various hardy fruits in the district of which Gordon Castle is the centre. The following plants were tabled for inspection :—Stand of *Violas* and Alpine plants by Dicksons & Co., collection of Alpine plants by Mr. Robertson Munro, one *Auricula* by Mr. W. Young, bunches of flowers by Lady Gertrude, *Viola* by Mr. John Gray, four Alpine *Auriculas* by Mr. G. McClure, one *Primrose* by Mr. John Fraser, and *Primroses* by Mr. G. L. Brown.

TREE FERNS.

IN the course of years one has now and then met with illustrations of arboreal Ferns, either in works on horticulture or trade catalogues, or illustrated papers, &c., yet in no instance that one can call to mind are Tree Ferns represented as they are actually seen growing in many sheltered places. These plants under cultivation in Europe seem to have undergone some trimming process near akin to shaving amongst weak mortals ; here you may see *Dicksonias* bearing their old fronds in a variety of warm shades of ruddy brown. A few days since I counted upwards of fifty layers on a fine old tree, the

accumulated fronds depending in cloak-like fashion with sweeping folds from the crown to the ground. With *Cyathea dealbata* this habit is less constant. Only this day I was rambling amongst some lofty specimens of *Hemitelia Smithii*, which in many instances carried rich coverlets of the old persistent fronds. Are old fronds cleared away from want of space, from notions of tidiness, or from a whim of fashion? Possibly fashion authorises this custom of denudation. I have known a barbarous gardener tear away the natural covering of *Cordylines* till a good reason was offered to his notice. Why, he had better sacrifice his ideas of tidy nakedness, and suffer Madam Nature to arrange her toilet in her own graceful method.—THOS. H. POTTS, *Ohinitahi, New Zealand.*

DOUBLE AND SEMI-DOUBLE WALLFLOWERS.

IN a recent number of the Journal "A SPRING GARDENER," at page 225, earnestly draws attention to the propagation, culture, and charming effect of this, I will say, almost incomparable spring flower—incomparable for outdoor culture when well grown. If you will permit me I will endeavour to enlist the sympathy of your readers for a more extensive culture of this favourite flower and say what I mean by "well grown," premising my remarks by a few observations on propagation.

If new varieties are wished for you must look to raising plants from seed, but the most convenient, certain, and effective mode of increase is propagation from side shoots as early as they can be found in spring. If your plants produce no offshoots cut down the flowering spike and mulch or give liquid manure to encourage their growth, so as to afford cuttings. I give a preference to the former, as they can be had earlier generally, and rootlets are more certain when you have a "heel" and there is then less liability to damping-off. A great object should be to have your plants coming into flower in early winter, when other ornamental flowers are scarce out of doors; you cannot therefore have your future young plants too early. For securing plants for early blooming, their growth might be expedited by starting in a cool frame; but under ordinary circumstances the side shoots referred to will root readily in a sunny border in light sandy soil, and to make certain of your plants the varieties should be labelled. For bedding, border, balcony, or window what can compare with a well-grown double or semi-double Wallflower during the winter and spring months, requiring so little care and yet so fragrant and brilliant in colour? As an amateur I value the plant for those qualities, and will not compare it with those brilliant but evanescent beauties that "sparkle like a meteor and are gone." I enclose you a spike of the first to hand in bloom since last November, and that, you will observe, would take another month to unfold its petals. The colour is peculiar—pale red and yellow softly shaded into each other. The spike is 10 inches in length, and would doubtless be nearly a foot when fully expanded. Four more similar spikes yet continue blooming on the same stem. Much better ones have ceased flowering. This is semi-double and would produce seed, and (making allowance for bee and foreign impregnation) with tolerable accuracy the same variety. At a recent visit to the seat of Mr. John Bagwell, Marfield, one of the most conspicuous features in a charming spring garden was a brilliant display of many varieties of Wallflowers in central chain beds—a glorious contrast of the plain and useful with the picturesque and grand around.—W. J. M., *Clonmel.*

[The spike received is both novel and fine.—EDS.]

PORTRAITS OF PLANTS AND FLOWERS.

LOXOCOCCUS RUPICOLA. *Nat. ord., Palmæ. Linn., Monocæcia Polyandria.*—"This elegant Palm is a native of rocky places in forests of the southern and central parts of Ceylon, from whence seeds were sent to Kew by Dr. Thwaites, F.R.S., Director of the beautiful botanical gardens of the island. Dr. Thwaites describes it as attaining the height of 30 to 40 feet, and adds that the seeds are chewed by the Cinghalese with their betel as a substitute for those of *Areca Catechu*. It flowered for the first time in the Victoria house at Kew in February of this year, and from its graceful habit and its coral-like inflorescence it was a most attractive object."—(*Bot. Mag., t. 6358.*)

ACOKANTHERA SPECTABILIS. *Nat. ord., Apocynæ. Linn., Pentandria Monogynia.*—"Mrs. Barber writes that the seeds are intensely bitter, and the whole plant considered by the natives to be a deadly poisonous one. The genus is, as Mr.

Dyer has remarked, too closely allied to *Carissa*, differing chiefly, if not solely, in the want of thorns. *A. spectabilis* is a native of the western districts of South Africa, from Albany to Port Natal, where it forms a large shrub, with masses of white very fragrant flowers, on woody sand hills near the sea. It was introduced by Mr. B. S. Williams and exhibited by him in 1872. Our specimen flowered at Kew in February of the present year."—(*Ibid., t. 6359.*)

AMBROSINIA BASSII. *Nat. ord., Aroideæ.*—Sir J. D. Hooker says, "For the opportunity of figuring this singular and interesting little Aroid I am indebted to Mrs. Grant Duff, who accompanied her husband, Mr. E. Grant Duff, M.P., F.L.S., of York House, Twickenham, to Algeria in the winter of this year, and brought living plants, which she presented to the Royal Gardens, and which, being in bud, flowered in February. It is one of the most curious of European plants, presenting with something of the habit of *Asarum* a floral economy in many respects resembling that of some of the terrestrial Orchids."—(*Ibid., t. 6360.*)

GREVILLEA ERICIFOLIA. *Nat. ord., Proteacæ. Linn., Tetrandria Monogynia.*—"G. ericifolia was raised from seeds sent by Baron Von Mueller, F.R.S., of whom it is not too much to say that he is the greatest colonial botanist that has ever lived, alike eminent as a traveller, a collector, and a describer of the vegetable products of his adopted continent. It has a wide range in Australia, from the interior of New South Wales to Melbourne and Port Philip."—(*Ibid., t. 6361.*)

CROCUS ETRUSCUS. *Nat. ord., Iridacæ. Linn., Triandria Monogynia.*—"We owe this interesting addition to our stock of cultivated Crocuses to the enterprise and energy of Mr. George Maw. Before 1876 not even a dried specimen had reached England, and it was known to us only by the description of Parlatore. Mr. Maw undertook an expedition to Italy expressly for the purpose of hunting it out, and after much trouble succeeded in accomplishing his object. The locality where he obtained it was Salita de Filetto, near Massa Maritima, in the Tuscan Maremma, where he found it in plenty in full flower at the middle of March."—(*Ibid., t. 6362.*)

SENECIO SUBSCANDENS. *Nat. ord., Compositæ. Linn., Syngenesia superflua.*—"A very fine hothouse climber, which has been for many years cultivated in the Palm house of the Royal Gardens, to which it was presented by the late Dr. Welwitsch. It was first described from Abyssinian specimens, but it has also been found by Meller during Livingstone's Zambesi expedition near the Murchison Falls. It belongs to a small scandent section of the genus, of which there are several tropical African and South African species. In the Palm house it forms a rambling herbaceous climber, trained up one of the iron girders, and flowering freely in January."—(*Ibid., t. 6363.*)

GLOIRE DE DIJON ROSE.

I WAS very pleased to see my remarks on *Maréchal Niel* Rose so ably verified by Mr. Moorman at page 332. "A thing of beauty" is said to be a "joy for ever." A *Maréchal Niel* Rose bush in full bloom cannot always remain beautiful, but most assuredly the recollection of it will not fade with the fading flowers. The Rose which heads these notes is equally well known as the *Maréchal*, and in some respects it is a more desirable Rose. I hope this does not look like detracting from the *Maréchal's* unique merits, but the free way in which the *Gloire* blooms in the open air gives it the advantage over the *Maréchal*.

Those who only grow a few sorts and do not include *Gloire de Dijon* make a great mistake, as it is the first Rose to come into flower in the spring and the last to cease flowering in the autumn. During some years and in some localities it actually blooms all the year round. With us it produces many fine flowers against an open south wall in April, and the tree continues yielding fresh blooms until November. The flowers have not then the irresistible attraction of blooms of *Maréchal Niel*, but they are not by any means deficient in either form, fragrance, or colour, and when cut just before half expanded they are quite elegant. Yet, well as this Rose does out of doors, it does better under glass, especially in the spring months, and I would advise all who can spare room to grow one or more plants of it under glass for supplying cut flowers. We have cut many dozens of fine blooms from a plant climbing up a pillar and running along some wires in the conservatory here during the last two or three months. The flowers are produced in great numbers, and as each new batch of shoots is formed a succession of blooms follows. Excepting

Maréchal Niel I would rather have the old Gloire for producing Roses under glass than any other variety that I am acquainted with.—M. M.

CAPE HEATHS.—No. 5.

MAY.

RESUMING our subject from last month, we now suppose that the repotted plants will be rapidly making roots and also growth, the late very genial weather we have experienced having been specially suitable to them; therefore the frames, pits, or houses should be opened upon all possible occasions, and even during a gentle shower the plants should be left exposed. It will, however, be well to carefully examine them

Fig. 57.—*Erica princeps*.

and water any that are dry, else the rain will only moisten the surface, and thus lay the foundation for that great pest mildew. This plague to Heaths does not show upon them very much so early in the season, but they must be carefully watched for it, and when discovered let them without delay be dusted with sulphur, which, however, should not be used in sufficiently large quantity to disfigure the plants, neither should it be allowed to fall upon the soil, as it is very injurious to the roots. From amongst the numerous kinds which are now in flower we select the following, all of which are deserving of general cultivation:—

E. physodes.—Unfortunately this elegant species is now rare in collections. It is a dwarf but erect-growing plant, producing whorls of little branches. Leaves arranged in fours, linear, obtuse, and spreading; the margins glandular. Flowers terminal, mostly in fours, pendant, and pure white.

E. propendens (fig. 56).—This is an elegant spreading and much-branched plant, bearing a profusion of flowers upon the small pendulous branches. Leaves in fours, linear, reflexed with age, slightly downy, and light green. Flowers mostly in pairs, bell-shaped, and reddish purple.

E. princeps (fig. 57).—A strong-growing shrubby plant, producing stout branches and large terminal umbels of bright flowers. Leaves arranged in fours, recurved, linear, abundantly

furnished with bristly hairs, and dark green. Flowers large, in umbels of five to ten, flask-shaped, with a much-swollen base; colour bright fiery red.

E. Cavendishiana.—A strong, erect-growing, and vigorous plant. Leaves mostly in fours, linear, smooth, and intense rich green. Flowers large, tubular, terminal on the smaller branches, and produced in great abundance; colour clear golden yellow.

E. ferruginea.—An elegant plant with closely-set foliage. Leaves linear, slightly spreading, profusely clothed with rusty-coloured hairs at the margins, and pale green. Flowers terminal in large whorls, tubular, and about an inch long; colour deep shining red, suffused with rose towards the mouth.

E. affinis.—A very handsome garden variety, resembling *E. Cavendishiana* in habit and colour of flowers; it differs in the yellow being much paler, and in having a close contracted neck to the flower, whilst in the kind just named the mouth is quite open.

E. primuloides.—This is a very compact and dense branching little shrub. Leaves mostly in fives, much crowded, linear, smooth, and dark green. Flowers in fours or fives, erect and terminal, neck contracted, base much swollen; colour bright shining red; segments of the limb spreading, pure white above, with a deep red eye.

E. Monsoniana.—A robust, erect-growing, and much-branched shrub, now unfortunately extremely rare in cultivation. Leaves arranged in fours, linear, obtuse, somewhat spreading, and deep green. Flowers in threes, large, tubular with a contracted neck, pendulous, pure snow white, and terminal on the small branches, thus forming a dense long spike of bloom.

E. obbata.—A fine robust branching shrub. Leaves arranged in fours, reflexed, hairy, and light green. Flowers terminal, much inflated at the neck; limb large and spreading; pure white.

E. obbata umbellata.—This is a grand variety of the preceding, differing principally in the larger flowers, which are slightly squared at the base, and also in the larger number of blooms in the umbels; colour pure shining white.

E. suaveolens.—An erect-growing somewhat lax-branched species, producing very large clusters of sweet-scented flowers. Leaves ascending, arranged in sixes, linear, smooth, and dark green. Flowers in clusters of twenty to forty, cylindrical, and soft creamy rose in colour, which becomes tinged with purple by exposure.

E. aristata major.—A splendid variety, in habit dense and much branched. Leaves arranged mostly in fours, recurved, furnished with a long stiff hair at the point, and dark green. Flowers in fours, upon long coloured footstalks, and terminal upon the smaller branches; blooms large, tubular, deep shining reddish purple; segments of limb flat, white at the margin, deep blackish purple at the base.

E. McNabiana (fig. 58).—A very useful and ornamental kind, of which there are several varieties, which differ only in the colour of the tube. Leaves in fours, stout and obtuse, the ends armed with stiff, bristle-like hairs. Flowers in umbels near the apex of the branches, upwards of an inch long, cylindrical, slightly swollen below the middle, rosy red at base, increasing to deep red towards the neck; limb large, and spreading white.

E. Beaumontiana.—A handsome species when in flower. It is a shrubby-growing plant, producing many slender flexuous branches. Leaves mostly in fours, linear, flat above, channelled beneath, ciliated, and pale green. Flowers three to six, terminal on the smaller branches, bell-shaped, with a reflexed margin, pure white.

E. depressa.—A dense compact-growing plant of great beauty, the peculiarly depressed or downward growth of its branches giving rise to its name. Leaves arranged in fours, stout, and blunt-pointed; colour intense deep green. Flowers mostly in threes at the ends of the branches, cylindrical, about an inch long, and rich golden yellow in colour.

E. florida.—An erect-growing kind, with numerous slender branches. Leaves in threes, linear, obtuse, smooth, and pale green in colour. Flowers in threes, terminal upon the small branches, pendulous, bell-shaped, sweet-scented, and delicate rosy pink in colour; footstalks and floral leaves or bracts same colour, which adds materially to the general display.—W. H. G.

GLOXINIAS.

Few if any dwarf-growing, summer-flowering, decorative plants combine such massive beauty of foliage with handsome

and variedly coloured flowers as do Gloxinias. Great improvements have been effected in this genus during recent years, and many fine varieties have been raised by both English and Continental cultivators. Messrs. Veitch & Sons have on several occasions exhibited flowers of fine form, great substance of petal, and rich and clear colours. Mr. Williams has also staged now and then remarkably fine flowers, and at the last exhibition at South Kensington Mr. Wills "came out" with a splendid group of seedlings raised at Anerley. At the same exhibition, too, a singularly fine collection was staged by Mr. Barron, the plants having been grown at the Royal Horticultural Society's Garden at Chiswick. Many of the flowers in this collection were remarkable for the chasteness of their markings, and their merits demand fuller notice than could be accorded to them in the report of the meeting referred to. The following are a few of the finest varieties in this very fine collection:—

Lord Derby.—An upright flower, alike striking by the purity of its throat and the rich contrasting colour of its lobes. The throat is spotless white, and lobes rich violet shaded with pale purple. Very fine.

Dominico Scassi.—Upright, pure white throat; lobes celestial blue. A very attractive and fine variety.

Boule de Feu.—Upright. A large flower of stout texture; colour glowing crimson scarlet. Very rich.

Boule de Neige.—Upright. Pure white, very free. Mont Blanc is equally pure and also larger, but apparently not quite so floriferous.

Madame Thibaut.—Upright. White ground, densely and regularly spotted with rosy crimson and purple. A splendid flower.

Madame Courant.—Upright. Deep and pure white throat spotted with violet; deep violet lobes. Very fine.

Madame Boutard.—Upright. Very free; flowers of fine form, throat much shaded and spotted; segments rosy pink.

Mon Caprice.—Upright. Pure white throat; segments curiously shaded with purple and rose.

Etna.—Semi-drooping. Glowing crimson. Bold and fine.

Madame Haines.—Drooping. Colour rich crimson, edge of lobes paler, pure white throat.

Gloria Mundi.—Drooping. A very broad and fine flower. Colour rosy crimson, white throat with a bright scarlet band.

Alice.—Drooping. Colour rich purple; very dense. A neat and attractive flower.

The twelve varieties named all possess features of excellence, and are worthy of being grown wherever conveniences for growing them are afforded. Provided a moderately heated stove, or even a shelf not too densely shaded in a vinery, are afforded, Gloxinias can be grown in a satisfactory manner. They are of the easiest cultivation, and if due attention is bestowed on them they are seldom troubled with insects. They are increased by leaves inserted now in light sandy soil and placed in heat until tubers are formed, which will produce fine flowering plants next year. They are also readily increased from seed, which may be sown any time from now until August. The tubers so raised will be strong by the autumn, and next year will form plants of great decorative value and much superior and earlier than when the seed is sown early in the spring and the plants are flowered the same year.—J. W.

SHADING FERNS.

A FEW bright days about this time remind us that extra attention will be required to the ventilation of plant houses; and if shading is to be used it should be looked to and got ready. Shading for some plants is necessary at certain times, but the difficulty is to know what amount of shade is required for each class of plants under cultivation. Our idea is that the less shading plants get the better. We have often been asked, Do Ferns require much shade? It is not easy to give a proper answer to such a question without knowing the other conditions under which they are cultivated. If a fernery be so thickly shaded as to exclude every direct ray of sunshine, and with a high moist temperature and rather a limited amount of air, syringe the plants twice a day and throw plenty of water about the floors. Under these conditions the plants will grow fast and have a soft, green, fresh-looking appearance up till about October. From that time the work of destruction will go on, which no amount of skill or attention will be able to stop. Some of the fronds will turn yellow, brown rusty-

looking patches will come on them, and scale will be abundant. The plants will have such a wretched appearance that it will be necessary at times to cut off quantities of fronds till there is nothing left but the skeleton of what should have been good plants. The very low temperature during severe weather, or the drip from the roof, or some other such cause will be blamed, when the fault really is in the summer treatment. Cases of this kind are to be met with in every locality where plants are grown in a higher temperature than that of a greenhouse. I have found treatment nearly the reverse of this to suit the majority of Ferns grown for decorative purposes. Whatever shading is used it should be of the lightest description, and only to break the direct sunshine. The plants should be as near the glass as possible, and receive as much as possible of the morning and afternoon sunshine, in fact in some localities all the sun they can get. Abundance of air should be given them early in the day without lowering the temperature. Under such treatment more attention will be required to watering, the plants will make a firmer and hardier growth, they

Fig. 58.—*Erica McNabiana* (see page 376).

will keep their foliage fresh till the old is replaced with young fronds, insects will give but little trouble, they will stand a much lower temperature in winter, and the fronds, if used for cutting, will last much longer. Ferns growing in a state of nature are often met with enjoying the full sunshine for at least half the day. Some plants of the Tunbridge Fern growing here wild enjoy the full sunshine till about nine o'clock in the morning; other plants of it growing entirely in the shade are not nearly so fine. The only plants of the *Osmunda regalis* I have seen growing wild—and they were in great abundance and luxuriance—was in a position where they were exposed to every blast of sun and wind. These were growing on an Irish bog, round the edge of a pool of water.—P. GRAHAM, *Leyeswood, Sussex* (in *The Gardener*).

NOTES ON VILLA AND SUBURBAN GARDENING.

NEVER, perhaps, have the real beauties of a garden been better displayed in May than during the present year. Under the influence of warm showers and otherwise genial weather there is not a tree nor a shrub that is not decked in its gayest attire and glowing in the fulness of its beauty.

It is a busy time in every department. The grass grows very rapidly and must be kept down by the frequent use of the mowing machine, for one of the principal points in a pleasure ground is the beauty of its turf. We prefer going over it frequently rather than setting the machine so low as to lay bare the roots of the grass, which machines will do if set very low. A happy medium is the best. Should the machine, however, miss any portion of the grass it may be advisable to mow it over again in the opposite direction, and any bents left after that must be taken off with the scythe, but on well-kept lawns this advice will not be needed. Plantains, Dandelions, and such like weeds on lawns must be destroyed by persistently rooting them up.

The recent heavy rains have been excellent for the keeping of walks in good order. Weeds have come out easily, and by the frequent use of the roller all has been made firm and solid. Cut grass verges frequently. We make it a practice to run the shears around the edges of the walks every Saturday; the walks are then swept and afterwards rolled with a heavy roller, this maintains them in excellent order, and the work is less heavy than allowing the verges to grow for a longer time, and then having a good clear-up, which we find is the case in many small gardens.

Roses.—We anticipate a splendid Rose season. The shoots have broken strongly and are getting into splendid leafage, and timely attention must be given them. Nature is doing her part well; we must assist her in freeing them entirely from attacks of aphides and caterpillars, which too frequently infest the young growths. Green fly is perhaps not quite such a destructive pest as the Rose maggot and caterpillars, still the aphides impede healthy growth, without which it is impossible to have good flowers. A tolerable free use of the garden engine will generally clear away the aphids, but to rid the trees of the maggot and caterpillar hand-picking is the only real cure. The pest can easily be detected by the leaves curling up, or two leaves sticking together. A simple pressure between the finger and thumb is sufficient to kill them. While doing this we find it a very good plan to pull off all ridged and despoiled foliage, as well as to thin out any weakly growths that will not bloom. This imparts to the stronger growths more vigour, and better wood is made for next year. Remove any suckers that may arise from the roots of either the Manetti or common Briar, also from the stems of standards, and place supports to such as require it.

From now to the end of this month may be considered safe to commence the bedding-out of the summer occupants of the flower garden. Let everything be well prepared, and commence with Calceolarias, Geraniums, Ageratums, and Petunias, reserving the more tender plants for fear of an unwelcome change in the temperature. Many of the flower beds are still gay with spring flowers; these as they fade must be taken up and removed to the reserve garden. Have everything in readiness, both plants and plans, so that no time be lost in making the beds gay for the summer.

Hardy Fruit.—The prospects of most kinds of fruit could scarcely be better, and we may now begin to feel that we are comparatively safe, as the foliage in most cases has become sufficiently developed to protect the embryo fruit. Unremitting attention is requisite to ward off green fly, which is becoming plentifully enough already. A dusting with tobacco powder and a free use of clear water distributed with great force from a garden engine are the best remedies to apply. Pick off all leaves of Peaches and Nectarines that are curled and blistered, and rub off any superfluous or foreright growths. Strawberries are now throwing up their flower stems very plentifully, and should have some clean straw or long stable litter that has been laid to sweeten placed around and between the plants, to protect the fruit from becoming gritty during heavy rains and to arrest evaporation. The applying of the material cannot now be done too soon.

Kitchen Garden.—The principal work here for the present will be killing weeds and the thinning of advancing crops of Onions, Parsnips, Carrots, Turnips, Spinach, Lettuce, &c. It is not always a good plan in a small garden to thin to the extreme limit at first, as many things—such as Spinach, Onions, and Carrots—can be pulled while small and used in the kitchen; but, on the other hand, do not allow them to become crowded and consequently interfere with each other's progress. Parsnips and Turnips thin to a foot apart. Lettuce transplant in rows a foot apart and the same distance from plant to plant. Make further sowings of Turnips, Spinach, Lettuce, Radishes, and other small salads. Paris White Cos Lettuce is a good variety for summer use, and red and white Turnip Radish. French Breakfast Radish is very good for a quick supply, but it does not keep good long. The main crop of Runner and Dwarf Kidney Beans should now be made. The variety known as Champion Runner is one of the best, and should be planted in a well-manured piece of ground in a very open space; it is useful also for running up palings or for blocking out any unsightly object. Canadian Wonder is one of the best and most prolific of the dwarf varieties; it produces an immense crop of long straight pods. Negro Long-podded is also another very good variety, and does well in most places. Prick out Celery on an open piece of ground, and sturdy plants will soon be provided for planting in the trenches. Vegetable Marrows should be hardened off and planted either on a heap of decayed

refuse and soil, so that the growths may run down all over the surface, or a trench may be taken out about 4 feet wide and filled in with partly spent manure such as been used for the linings of hotbeds, covering the whole over with a good depth of soil. Plant on the top of this and cover with handlights. The plants will soon be established, when the handlights may be removed and the plants left to grow at their own free will.

NOTES AND GLEANINGS.

We are pleased to learn that Her Royal Highness the Princess Louise (Marchioness of Lorne) has been graciously pleased to consent to **DISTRIBUTE THE PRIZES** at the Whit-Monday Popular Flower Show, to be held at the Royal Horticultural Society's Gardens.

—THE usual monthly dinner of the **HORTICULTURAL CLUB** took place on the evening of the 7th inst. Some magnificent Asparagus was sent for the dinner by Mr. Arthur Dickson of Chester grown on the Cheshire coast, which in size and excellence was quite equal to French-grown produce, and had moreover the advantage of a much larger proportion of the edible portion. We understand that it is in contemplation to have a special dinner on the opening day of the Royal Horticultural Society's great Show.

—WE have received the schedule of the southern section of the **NATIONAL CARNATION AND PICOTEE SOCIETY'S SHOW**, which is to be held at South Kensington in conjunction with the meeting of the Royal Horticultural Society on July 23rd. Those who visited the Society's Exhibition in the Westminster Aquarium last year could not fail being impressed with the superlative beauty of these favourite hardy flowers as staged by the chief cultivators. We trust the forthcoming display will be still larger, and hope especially that competitors from the midlands and the north will have a share in the honours provided. Both the weather and the date of the Show are favourable for northern growers whose plants cannot but be in an advanced state, and may, it is hoped, by a little coaxing be had "in" by the day of exhibition, which is five days later than the show of last year. Last year it may be remembered that the best of the southern flowers had been accelerated by the plants having been placed under glass; this year it is probable that they will have to be retarded. A good chance is this year certainly afforded to the northerners, and we trust they will make the best of it. The prizes are numerous and liberal, and are open to all exhibitors, whether subscribers or not. Schedules can be obtained from the Hon. Sec., Mr. E. S. Dodwell, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W.

—WITH the consent of the authorities of the Royal Botanical Society of Manchester, members of the **NATIONAL ROSE SOCIETY** residing in the north of England can have two tickets for the Manchester Show and one for the Crystal Palace, instead of one for Manchester and two for the Palace.

—AT a Committee Meeting of the **WEST OF ENGLAND ROSE SHOW** held on May 8th it was agreed that the entry fee, £2, to be paid by exhibitors in class A 2 (open to nurserymen not residing in Herefordshire) should be cancelled in the schedule lately issued to the public.

—THE Scottish Horticultural Association, which continues doing useful and practical work, has agreed to offer prizes of £3, £2, £1, and 10s., for **COMPETITION BY UNDER GARDENERS**, members of the Association, for the best four plans of kitchen gardens, with fruit, plant, and forcing houses, gardener's house, and offices complete. The plans to be drawn to a scale of one-twelfth of an inch to the foot. The whole area included not to exceed five acres; three and a half acres being devoted to the kitchen garden including outside slips, and one and a half acre to the houses, offices, and yards. Sections and elevations of the stipulated glass erections, showing the arrangements for heating and ventilating, to be given on a separate sheet, to the scale of one-fourth of an inch to the foot.

—WE have received from a correspondent at Bognor flowers of a double variety of the common **CUCKOO FLOWER** (*Cardamine pratensis*), which grows wild in his neighbourhood. Our correspondent states—"The variety grows in some abundance in certain localities, and often by the side of the single variety. The habit of the plant is much the same as that of the latter, and the leaves on the flower stems and also the larger leaves are alike. In one respect the double variety differs from the single—viz., in the flowers being often produced, not in a cluster on the top of the stem, but throughout the greater part of its length, after the manner of the *Rockets*."

The flowers are quite double, pale lilac in colour, and very attractive. It is not common.

— **Messrs. Dick Radclyffe & Co.** exhibit at the **PARIS EXHIBITION** a fernery. It is attached to the boudoir of the Royal pavilion provided for the use of His Royal Highness the Prince of Wales. The same firm exhibit a window conservatory and aquarium, and four cases of dried natural flowers.

— **MR. L. I. KNOX** writes to us—"On the 8th of this month my gardener in my presence gathered two large opening buds and one full-blown **GLOIRE DE DIJON** ROSE growing on a wooden trellis against the wall of my house at Caversham, Oxon, which has a western aspect. There are many buds largely developed ready to succeed them next week."

— **IN** reply to some correspondents **Mr. D. Sewell** writes as follows on **STOCKS FOR ROSES**:—"I consider that no law can be laid down as to the best stocks for Roses, as the habit of the Rose has so much to do with the success, as well as soil and situation, which can only be acquired by practical experience. I work upon standard, Briar, Manetti, and seedling, and grow a few Roses on their own roots. I prick into the soil old cow manure in the spring that has been used for Cucumbers the previous summer, as my soil is a light loam upon gravel, and then supply the Roses with weak liquid manure at the root during the growing season; I also give copious syringings."

— It is singular that the well-known and deservedly popular bedding **GERANIUM VESUVIUS** should be sportive while other varieties are generally so constant. Amongst the sports that we have seen from the old variety, and all good, are Wonderful, semi-double; White Vesuvius, pure white; and striped Salmon Vesuvius, and a double striped Vesuvius. We recently saw at Chiswick a truss of the single striped variety producing flowers quite different from any of the varieties alluded to; they were oculated and exactly resembled flowers of the good old variety **Amelina Griseau**. Trusses of the double striped variety alluded to have been sent to us by **Mr. Knight**, North Trade Nursery, Battle, Sussex. The trusses are very fine, each have upwards of forty pips and unexpanded buds; the flowers being semi-double, bright orange scarlet in colour, the petals being further clearly striped with white.

— **ON** the wall of climbers at Chiswick **PIPTANTHUS NEPALENSIS** has lately been flowering very freely, and its large golden Cytisus-like flowers were very bright and attractive. In sheltered situations in the southern counties this plant is usually grown as a shrub, but is evidently well adapted for training to a wall from 6 to 9 feet high. Flowering chiefly, indeed almost entirely, at the extreme ends of the branches, it must not be pruned. It is a very ornamental flowering shrub, and was introduced from Nepal in 1821; yet, although it has been in English nurseries and gardens so long, it is by no means common. It is sometimes called **Anagryis indica**.

— **ON** the **ROCKWORK** formed near the large vineery at Chiswick the plants have become established with noteworthy rapidity. This is the result of the work having been well done. Too often in forming rockwork a heap of stones, &c., is formed, and the soil is "worked-in" amongst them. This is just the wrong way of doing the work, and always results in disappointment. A deep and firm foundation of good soil is the first essential to success; the stones can then be embedded in it, and the interstices afterwards be filled-in with free light soil for planting in. Amongst the plants we recently saw flowering in the Chiswick rockery were **Cheiranthus alpinus**, very gay; **Saxifraga Wallisii** from Messrs. Dickson & Co., Edinburgh, a fine rock plant, larger than **S. geranioides**; **Ranunculus amplexicaulis**, distinct and pleasing; **Narcissus Bulbocodium**, very bright and attractive; **Iberis petraea**, a little gem; **Pulmonaria sibirica**, with pretty marbled foliage and blue and pink flowers; **Veronica serpyllifolia** var. *alpina*, a lowly and lovely rock plant; **Veronica pectinata**, brighter than **V. Chamædis**, **Gentiana verna**, **Alyssum**, and **Alpine Phloxes**. Thanks to **Mr. Webb** for giving the stone, and to **Mr. Barron** for turning it to such good account, also to many friends who have sent plants, the rockwork at Chiswick will shortly not only be attractive, but, like other features of this experimental garden, will be instructive.

— **LAST** Sunday was what is known amongst the working classes of London as "**CHESTNUT SUNDAY**," so called as being the first in the season on which the Chestnut trees which form

the noble avenue of Bushey Park Royal demesne are in their best bloom. Large numbers went by rail and river to admire the famous trees which now present a magnificent appearance, both the flowers and foliage being unusually fine this year.

— **MR. LEGG**, who managed **Mr. Ralli's** garden at Cleve land House so successfully, and who relinquished his charge there last autumn, has been appointed gardener to **A. Southard**, Esq., Fern Lodge, Ascot. The garden is of moderate size, and is much cherished by its owner, who has made provision to have it conducted well. When a liberal employer and able gardener both work to the same end good results are sure to follow.

— **NEAR** the coast of Suffolk are the ruins of Dunwich Priory, and in the clefts of those ruins grows the **DUNWICH ROSE**. This Rose is said to have been brought by monks from Normandy many centuries since, and that it will grow nowhere else. It degenerates when cultivated and resembles the Scotch Rose. It is a powerfully scented flower, rambles over the surfaces of the cliffs, and is known to botanists as **Rosa arvensis**. The flower has a powerful scent; is a single blossom of purest white velvet, with anthers of black or brown, a smooth brown stem with long sharp thorns, and smooth pointed dark green leaves growing like the Blackberry leaves.

WORK FOR THE WEEK.

KITCHEN GARDEN.

It is important that plants of all kinds which have passed their season of usefulness be promptly removed, as they are not only unsightly in appearance, but they also impoverish the soil. Old stems of Brassicas will no longer be required to afford sprouts, as their place will be taken by early Cabbages, and Winter Spinach will be succeeded by spring-sown produce. Remove, therefore, every crop of those descriptions when of no further use, manuring and preparing for other crops without delay. Early Cabbage ground will answer for Celery or late Peas, similar remarks applying to ground previously occupied by Broccoli and Winter Greens. A good breadth of Peas for use in late summer should now be sown, also Broad Beans. Make successional sowings of Turnips. In hot dry soils they should be grown on a north border. Early-sown crops should be attended to in thinning and watering. If fly appears upon Turnips or other crops dust them with quick-lime or dry wood ashes. Prick off young plants of Broccoli, Cauliflowers, Brussels Sprouts, Savoy, &c., when they are large enough for the purpose. The earliest-sown Brussels Sprouts should be planted out so soon as ready, allowing them plenty of room—a yard distance every way. Sow Cauliflower for autumn use. Lettuce sow in drills, thin early, avoiding transplanting. Continue making successional sowings of Radishes and small saladings. Spinach to maintain a supply should be sown every fortnight; in dry soils sow in a north border. If Endive be wanted early a small sowing may now be made. The seed should be sown where the plants are to remain; thin them to 15 inches distance apart every way. Round-leaved Batavian and Green-curbed are the best. Asparagus will require cutting daily. We prefer to cut with a small portion of blanched stem, it having a better appearance, but care is necessary so as not to destroy advancing heads. If it is necessary to cut from roots intended for forcing the cutting must not be prolonged, or the roots will be too much weakened for that kind of work. The benefit of a mulch of half-decayed manure to all kinds of vegetables is very marked in dry soils and in hot weather whatever the soil may be. The mulching arrests evaporation, preserving an equality of moisture at the roots so essential to the production of vegetables of high quality.

FLOWER GARDEN.

Seeds of biennials should now be sown. Such plants as Canterbury Bells in blue, white, and rose varieties, with doubles of the two former colours, and the superior calycanthema and its white variety, ought to have a place in every garden. Indian Pinks too make a very fine display. Honesty, purple and white, are very gay in early summer, and their seed pods being semi-transparent are pretty ornaments in a dried state. *Oenothera Lamarckiana* is a stately plant; *O. biennis* very showy. Rockets are free-flowering and sweet-scented. Some perennials are best treated as biennials, such as Wallflowers, which are always acceptable from their fragrance, and should be grown in quantity; also Sweet William, than which few plants are more effective in clumps or masses in their season. Seeds of perennials should be sown. Propagation by seed is a ready mode of securing a stock of plants where plants of this kind are required in quantity. It is desirable to have an herbaceous border, and a good beginning may be made by raising plants from seed. Foremost are *Mr. Douglas's* superb *Columbines*—viz., *Aquilegia cærulea hybrida* and *A. californica hybrida*, all the *Columbines* being fine border plants flowering in early summer. The old-fashioned Rose Campion (*Agrostemma coronaria*) suits any soil. *Alströmarias* should be sown where they are to remain, their flowers are valuable for cutting. *Anchusa*

italica is a fine Borage-like plant. *Allium alpinum*, *Anthericum Liliago*, *A. ramosum*, *Aster alpinus*, *A. tenuifolius*, *Astragalus uralensis*, *A. narbonensis*, *Campanula lactiflora*, *C. macrantha*, *Cynoglossum apenninum*, *Delphinium formosum*, *D. grandiflorum chinense*, *D. imperiale*, *Gentiana asclepiadea*, *G. lutea*, *Gypsophila paniculata*, *Iris pulchella*, *I. sibirica*, *Liatris spicata*, *Libertia ixioides*, *Lychnis Viscaria*, *Lythrum roseum superbum*, *Meconopsis cambrica*, *Papaver nudicaule*, *Senecio Doronicum*, *Silene pulchra*, *S. regia*, *Sparaxis pulcherrima*, *S. Thunbergi*, *Trachelium cæruleum*, *Verbena venosa*, and *Xerophyllum asphodeloides* are all effective border plants. Those, with *Potentilla* (single and double), *Phlox decussata*, *Pentstemon*, *Lychnis Haageana hybrida*, *Geum atrosanguineum fl. pleno*, *G. coccineum*, *Digitalis*, *Antirrhinum*, and *Pyrethrum* double vars. should not be omitted; they are all more or less ornamental, readily raised in light soil in a sheltered border, covering each kind with fine soil to the depth of the diameter of the seeds or a little more, keeping the ground moist, pricking out the seedlings when large enough to handle, and transferring them to their permanent quarters in autumn or early spring. *Polyanthuses*, *Daisies*, *Anemones*, *Auriculas*, *Myosotis*, and other spring flowers should be raised in quantity, there being few places which do not afford appropriate situations for these attractive flowers. Rock plants may be raised from seed by sowing it in fine soil in a shady border, but not in the drip of trees, but preferably in pans in a cold frame, as the soil can be kept more uniformly moist until the seedlings are well up and in a fit state to transplant in a north border. Some that may be raised from seed are *Alyssum saxatile compactum*, *A. utriculatum*, *Antennaria dioica minor*, *Arabis alpina*, *Arenaria purpurascens*, *Aubrietia græca*, *A. purpurea grandiflora*, *Calandrinia umbellata*, *Campanula carpatica* and its variety *alba*, *C. pusilla*, *Dianthus neglectus*, *Erinus alpinus*, *Gentiana gelida*, *G. verna*, *Helianthemum piloselloides*, *H. tuberaria*, *Jasione humilis*, *Linaria alpina*, *L. pyrenaica*, *Linum flavum*, *L. salsoloides*, *Lychnis alpina*, *Orobis alpestris*, *Ramondia pyrenaica*; *Saxifragas* *Aizoon minor*, *affinis*, *ambigua*, *controversa*, and *rosularia*; *Sempervivum Bolli*, *Silene caucasica*, *S. Schafta*, *Solidago cambrica*, *Veronica saxatilis*, and *V. prostrata*. We know many prefer to raise their plants from seeds, and have not "gone in" for plants of this class from the supposed difficulty in securing stock in quantity. There is really no difficulty in raising a quantity of both herbaceous and Alpine plants from seed, which will afford a fine display at a much less cost than by purchasing plants. One of the greatest errors in herbaceous borders and rockeries is the planting in medley fashion single plants dotted here and there without any idea of producing effect—bits of blue or yellow, &c., instead of bold masses, as would be the case where, when the space admits of duplicates, planting the several plants together so as to form a group. In the case of rock plants it is the masses that tell, and not bits.

FRUIT HOUSES.

Vines.—Red spider is sure to come when the days are bright and the nights dry. One thing relating to this pest we have noticed, and that is its attacks are more certain when the roots of the Vines are confined to inside borders, and there is always a difference between those Vines with the borders part within and part outside the house than those with borders entirely outside. This points to the importance of affording water to inside borders liberally—not mere surface watering, but sufficient to reach the lowest roots. This thorough moisture at the roots and a plentiful supply of moisture in the house are the best means of avoiding red spider. If, however, the pest puts in an appearance painting the hot-water pipes with sulphur brought to the consistency of cream by being mixed with milk is the best remedy. We first apply it to the return pipes, and if that does not answer we paint the flows, and those being heated to 160° fumes are given off fatal to the spider. Some cultivators resort to the syringe. It will wash off the pest, and is equally destructive to the bloom of the Grapes—in fact fatal to good finish. Sponging and brushing the leaves is a tedious and at best but a partial means of riddance, sulphuring the pipes being by far the best remedy. Vines started early in January are now ripening. Though a rather drier atmosphere is desirable it is best secured by free ventilation, leaving a chink of air on at the top of the house constantly and admitting it liberally whenever the weather is favourable, as nothing contributes more to good finish than a good circulation of warm air after the Grapes commence colouring. The border if inside must have a thorough watering, and a mulch of half-decayed manure will secure moisture sufficient for the perfection of the crop; yet even when the fruit is ripe Vines must not suffer by lack of water at the roots. The temperature should be 70° at night, 5° less on cold nights, admitting air at 75° and increasing the heat to 85° or 90° with sun and full ventilation, reducing the ventilation at 80°, closing all but the small portion at the top of the house. Maintain good atmospheric moisture by damping the house two or three times a day, and keep the evaporation troughs replenished with liquid manure. Muscats are ripening and must not lack moisture at the roots: apply liquid manure if the crop be heavy and the Vines not over-luxuriant. The inside borders must be examined every week, and if moisture be required give it liberally and warm (90°). Muscats should have a temperature 5° higher all through than

Hamburgs, especially when ripening, if they are to have the fine amber colour so characteristic of thorough ripeness. Attend to stopping, removing laterals, tying, and thinning in succession houses. Late Vines, push forward as speedily as possible, maintaining a night temperature after the bunches show (which will be the case now with those started naturally—i.e., with the aid of solar heat only) of 65° to 60° at night, 70° to 75° by day, advancing to 85° from sun heat, admitting a little air at 70°, closing at 75°, and if the temperature afterwards advance to 80° all the better, as less artificial heat will be required at night. Upon the temperatures named rise 5° by the time the Vines are in flower, maintaining a good moisture but rather free ventilation whilst in bloom, and go over shy settlers with a camel's-hair brush when the pollen is ripe. Remove duplicate shoots, and stop those remaining two or three joints beyond the bunch. Duplicate bunches must be removed unflinchingly so soon as a selection can be made of the best in shape. Early-forced Vines with the Grapes ripe, having had fermenting materials applied to the borders, should have a part of it removed, leaving sufficient for a good mulch; and if, as not unfrequently occurs, the roots are active in the lower part of the fermenting material, a little fresh litter should be placed over the surface to protect them from the atmosphere; besides, it gives the border a neat appearance. Houses in which the Grapes are ripe will only need fire heat to keep the temperature at about 60° at night, ventilating freely by day.

Peaches and Nectarines.—Those in the house started early in January have stoned and must have abundance of water, with a mulch of short manure to prevent or lessen evaporation. Outside borders are often neglected—they become too dry. Examine them, give a good watering if necessary and mulch with short manure. Continue syringing the trees twice a day, and if red spider cannot be kept under by that means apply a solution of soft soap, 2 ozs. to the gallon, with a garden engine upon a calm evening. Attend to tying-in the shoots, stopping all laterals at the first joint, and pinching out the points of any shoots for next year's bearing exceeding a foot in length. If not wanted to push the fruit, which it is well to bear in mind cannot be done without risking the future welfare of the trees, the temperature may be maintained at 65° to 60° at night, 70° to 75° by day, increasing the ventilation at 70°, having it full at 75° if there is likely to be an advance, closing at 75°. With sun 80° to 85° or more may be allowed. See that the shoots in the succession houses are tied-in as they advance, thinning the fruit, ventilating early and thoroughly, and syringing morning and afternoon, examining the borders at least weekly, and applying water thoroughly when it is needed.

Cucumbers.—Plants which have been bearing through the winter now show signs of weakness and make short stunted fruit. Such plants may be renovated by cutting them well in and removing the soil from among the roots and replacing with fresh, but they never afford such satisfactory results as are obtained from young plants. We prefer growing our Cucumbers for summer use in pits or frames. Two or three three-light frames will afford a large number of fruits daily without fail from now up to October. This liberates the house for Melons, which may be planted at once. Young plants at all weak will be much assisted by the removal of the first fruits and male blossoms, stopping at the third or fourth joint, removing all superfluous shoots. Syringe at about 4 P.M. moderately, keeping the floors well damped. Shade only to prevent the foliage flagging. Pits and frames cleared of bedding plants may be occupied with Cucumbers. Very slight heat only is necessary; spent litter from Seakale, &c., with the addition of a little fresh manure will give all the heat required.

PLANT HOUSES.

Stove.—*Tabernaemontanas* are making free growths and should be encouraged by gentle syringing, but avoid making the soil sodden by too frequent watering, as they are rather impatient of water at the roots, requiring a much less quantity than many other stove plants, and on this account probably are less seen than their fine deliciously scented flowers merit. They are apt to cast the flower buds, especially if grown in too much heat. They succeed well in a cool stove. *Bougainvillea glabra*, *Allamandas*, and *Clerodendron Balfouri* are fine conservatory plants, and will now, if they have been started early, be in a forward state for bloom. We allude to those started in February and which have been brought on gently, as when brought on quickly in a high temperature they do not stand well in a conservatory. They should be flowered slowly and removed when the flowers are expanding, and they then last a long time, but must be kept from draughts. *Ixoras* are coming into flower. If intended for the conservatory they should have air moderately, be kept rather cooler, and have all the light possible. In that way they will stand much better than plants brought into flower in a hot, moist, close atmosphere. Similar remarks apply to *Stephanotis*, which is one of the most acceptable of plants for conservatory decoration when in bloom. Vines intended for late summer flowering—and very useful they are—should not be allowed to flower now but be kept stopped, which will induce a compact habit and a profusion of bloom. They should have a light moderately airy situation and be kept well supplied with water, potting them if required. Tuberous-rooted *Begonias* started early are now in bloom, and

fine they are for conservatory decoration. They should have a rather cooler and more airy situation before removal. Begonias for winter flowering, cuttings of which were inserted some time ago, pot off and grow on in a light airy position. Wage incessant war against mealy bug, scale, and other insect pests, for which there is no remedy equal to the "catch-and-kill" system. Scale is easily picked off with a budding-knife handle, and mealy bug may be kept under by frequent examination of the plants subject to its attacks; but once let those pests get ahead and nothing but disfigurement of the plants results from an attempt at cleansing them. Syringe well morning and afternoon, damping at noon, closing early at 80° so as to dispense as much as possible with fire heat, which will still be necessary to keep the temperature from falling below 65° in the morning.

TRADE CATALOGUES RECEIVED.

Dick Radcliffe & Co., 129, High Holborn, London.—*General Catalogue of Plants and Garden Requisites.*
Thomas Bunyard & Sons, Maidstone.—*Catalogue of Bedding-out Plants, Roses, Ferns, &c.*
Robert Wagstaffe, Russell Street Ironworks, Hyde, near Manchester.—*Prospectus of Cylindrical Boilers.*

TO CORRESPONDENTS.

. All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (R. C. Tucker).—We know of no book such as you describe. Brown's "Forester" is the most practical work for your purpose.

ADDRESS (H. G.).—The Secretary of the Oxford Rose Society is Mr. Edwin Thorne, Laburnum Cottage, Woodstock Road, Oxford.

BROCCOLI PLANTS (C. Ross).—Apply to any of the market gardeners who supply them retail.

MEDLAR (X.).—The specimen sent is a spray of the Medlar.

VICTOR MEMORIAL PRIZES (An Old Subscriber).—The prizes are offered for competition by amateurs and gardeners only, not by nurserymen.

EXHIBITING DELPHINIUMS (Tweedside).—We think you can compete with semi-double Delphiniums when it is mentioned in the prize list double. At any rate, semi-double flowers are not single, and we think ought not to be excluded from the class you mention.

WINDOW FLOWERS (J. Watson).—"Window Gardening for the Many" is published at our office. You can have it free by post, if you enclose twelve postage stamps.

SAPONARIA OCYMOIDES FAILING (A. Boyle).—This, like many other hardy perennials, suffers much in a wet winter if planted in a low damp situation. It answers best when trailing over masses of rock with plenty of well-drained rich gritty loam packed in behind and among the rocks for its roots. Failing the rocks you might easily contrive some little mounds for it, over which it would soon spread and form soft green cushions enriched with a mass of rosy flowers at this season of the year.

AGED SAVIN (L. C. H. E.).—The placing of the soil over the roots 18 inches deep would only tend to make matters worse. Remove all but an inch or two and leave the rest to Nature. We apprehend the shrub is, however, succumbing to age and will gradually decay, not unlikely go off in a few years. The shrub must be a fine one, having been a "large plant forty-eight years ago, and now 60 yards in circumference," a grand specimen. Our correspondent wishes to know if the Savin (*Juniperus Sabina*) is generally a long-lived plant. We should be obliged by information on the subject; but our experience points to its not surviving so long as many shrubs, probably from its being an Alpine, and in this country planted in low moist situations or rich soil, where it grows freely and soon decays.

CULTURE OF CRASSULAS (Eve).—You do not say what convenience you have for growing them nor what the kinds are. We presume you possess a greenhouse, and that the species is *Crassula (Kalosanthes) coccinea*. Take cuttings in August, shoots that have not flowered, and insert them singly in small pots in sandy soil, watering carefully. They strike freely and may be kept on shelves near the glass in a house from which frost is excluded, giving water only to maintain the foliage from shrivelling. When they commence growth in spring stop them at 3 or 4 inches from the soil, taking off a few of the lower leaves to facilitate their breaking, and when the young shoots are formed thin them to three or five upon a plant according to its strength. The young shoots being 3 inches in length shift the plants into pots 5 inches in diameter, and again in May or early June into 7-inch pots. In July place them outdoors in a warm situation at the front of a south wall, the pots being plunged in ashes. Water sufficiently only to maintain the plants fresh, avoiding making the soil sodden. Remove the plants to a light airy position in the greenhouse in late September. They will flower the following year. After flowering cut each shoot down to within an inch of its base. Disbud as before to three shoots on each branch. Repot in the same size of pot when the shoots are well broken, reducing the ball about a third, and in February of the following year shift into pots 2 to 4 inches larger in diameter according to the vigour of the plants. They should be freely watered whilst in growth, or from April to the middle of June, when place them outdoors and return them to the greenhouse as before. The following year they will be good specimens. The plants bloom from the one-year-old wood only, therefore two sets of plants are required.

All the shoots, however, do not flower, but we elect to cut down all the shoots after flowering whether they have flowered or not, thereby securing a regular break and bloom. Equal parts of sandy fibrous loam and peat, half a part of old cow dung or leaf soil, and one-sixth each of silver sand, pieces of charcoal, and broken pots, will grow them well, providing efficient drainage. If cuttings are inserted in July and not stopped, each plant so produced will with good management produce a terminal head of bloom in the summer following. A number of such small plants are often very valuable for decorative purposes.

VINE CUTTINGS (W. E. B.).—Pot them off singly when they have formed roots into 5 or 6-inch pots, and place them in the closest and warmest part of the greenhouse, shading them from sun until the potting is recovered from, after which they cannot have too much light. They should be sprinkled overhead morning and evening; and when the pots fill with roots, but before they become closely matted, shift the Vines into 9-inch pots. Apply liquid manure when the canes are growing freely, and allow all the laterals to grow at will. In September lessen the supply of water, affording no more than to prevent flagging, and at the end of the month place them outdoors in front of a south wall. When the leaves have fallen remove the Vines to a cool house, and in December cut them back to two eyes. Place them in the greenhouse in February, and when the shoots are 3 inches long turn the Vines out of the pots and remove as much of the old soil as possible from among the roots, and return them to the same size of pot. When this fills with roots again transfer to a 12 or 13-inch pot, and apply liquid manure when the roots are active in the fresh compost. Rub off one of the shoots, retaining one only to each Vine, and train this at about 1 foot distance from the glass. Stop the laterals at the second joint until the cane is 9 feet in length, when take out its point and allow the laterals to grow at will after they have been stopped at the second leaf, removing them altogether when the leaves fall. If you succeed in ripening the wood thoroughly you ought to have fruit the following year. Do not replot during the fruiting season, but top-dress. The Vines, after having been shortened in December to 5 or 6 feet, may be coiled around stakes or trained beneath the roof, being careful to depress the cane until the eyes have broken throughout its length, when it may be placed in position.

MILDEW ON VINES (R. A. W., Ipswich).—We never saw a worse case of mildew. All the bunches so severely infested as the one you have sent must be promptly cut off and burnt, and the others, together with the foliage affected, must be thoroughly dusted with flowers of sulphur, which, after remaining on for a few days, must be washed off with the syringe. Keep the atmosphere of your house drier and admit air more freely, and especially earlier in the morning. Unless you apply the remedy promptly and thoroughly your crop will be ruined. Leave a little ventilation at the top of the house all night. Keep the roots of the Vines moist; if they are in an inside border they are probably too dry.

VINES CROPPING INDIFFERENTLY (X. F.).—The most likely cause of the deficiency of crop is over-luxuriance, induced by the rich border material, aggravated by undue moisture, resulting in unripe wood. We should restrict the growth, stopping two joints beyond the fruit shoots not fruiting two joints beyond the first tendrils (clasper), and stop all growths from the uppermost lateral at the first leaf, removing all laterals below at every joint except the two lowest, which stop at the first leaf and repeat if necessary. The shoots should not be nearer to each other than 18 inches, so as to have the foliage well exposed to light, overcrowding alone often being fatal to fruitfulness. When the fruit commences colouring give the border a good watering and admit air freely, maintaining the temperature at 70° to 65° at night, 75° by day, increasing the ventilation at that, having full ventilation on at 85°, close at 75°—if it rise to 80° all the better; continuing these temperatures until the wood is brown and hard, not giving any more water to the border except to prevent flagging. A little air should be let on at night at the top of the house. If the house is planted with Muecata the temperatures should be 5° higher. When the wood becomes thoroughly ripe admit air very freely, and allow the temperature to fall to 60° at night until the Grapes are cut, and then admit all the air practicable day and night. Get the wood well ripened and you will have abundance of Grapes.

AMATEUR (Crece).—An amateur is considered to be a person who pursues some occupation for the pleasure it affords him.

SLATE versus WOOD SHELVES (Old Subscriber).—Slate is preferable to wood shelves, being more durable; the former being solid hold more moisture, consequently are cooler and better suited to hardwooded plants than lath wood shelves, but the latter answer very well both for hard or softwooded plants. No one in these days of cheap glass would tolerate squares 6 by 4½ inches. Ours are 1 foot 9 inches by 13 inches, 21 oz. thirds quality, and there is no scorching; but we shade the greenhouse from bright sun from April to September inclusive. In winter plants cannot have too much light. We have sheet glass 32 oz. in squares 2 feet 6 inches by 18 inches, and no scorching takes place; also polished plate in squares 4 feet by 3 feet 6 inches, and there is no scorching beneath any. Hartley's rolled patent answers well; we have it in squares much larger than those you name. We prefer 21 oz. thirds for general purposes, the squares not less than 15 by 9 inches, and not exceeding twice that size.

PERNS FOR GLASS CASE (Jdm).—*Lomaria L'Hermieri* for centre, *Adiantum Luddemannianum*, *Pteris serrulata* Leyl; or *Todea pellucida*, *T. Wilkesiana*, and *T. superba*. The last will ultimately become too large, but is very desirable in a small state for such a purpose.

KNOBS ON FRENCH BEAN ROOTS (Frank).—The roots are perfectly healthy. The knobs are common to all the podbearers. The creeper is, judging from the smashed specimen, *Manettia micans*. A glazier would probably tell you where you could get the diamond re-set.

MOSS IN WATERCRESS BED (T. R. C.).—It is due to poverty, and often from too great depth of water; 6 inches depth should be a maximum, 4 inches being deep enough. Give a dressing of thoroughly decomposed cow dung, and press it down with a board with a long handle fixed to it obliquely, and repeat after each cutting or about every three weeks during the growing season. A large barrowful is a sufficient dressing for 100 square yards.

SOOT WATER (Triops).—Tie up a peck of soot in a coarse bag or piece of old canvas and suspend it in a tub containing thirty or forty gallons of water. In a week you will have a stimulant of great value for all quick-growing softwooded plants. If you immerse a large lump of quicklime in the tub the soot water will become as clear as sherry. The solution will generally be sufficiently strong if diluted with half or more than half of pure water at the time of using it. As you take water out of the tub fill it up again. The bag of soot will last a considerable time, but of course th

longer it is in use the weaker the solution will be, and the less the need of diluting it. Liquid manure is not necessary for plants until the pots in which they are to flower become filled with roots; it is then of great value, indeed indispensable for the production of healthy foliage and fine and highly coloured flowers.

APPLE AND PEAR LEAVES (*Inquirer*).—They are blistered and otherwise disfigured by exposure to violent transitions from heat to cold, and *vice-versa*.

HORSE DROPPINGS FOR FLOWER BEDS (*G. S.*).—They may be spread on the surface of the beds an inch or more thick, according as the soil is rich or poor, and be forked-in. Geraniums usually flower sufficiently freely without much manure. Unless your soil is very strong the addition of leaf soil would not be an advantage. Your other question will be answered next week.

APHIS ON PEACH TREES (*E. R.*).—Pick off the very much curled and crumpled leaves. Boil 4 ozs. of quassia chips in a gallon of water for fifteen minutes and add to it four gallons of pure water, mixing it also with a little tobacco water, and with this syringe the trees. Tobacco water and quassia chips can be had from most large druggists and nurserymen. Frequent syringings with pure water are beneficial.

HEATING SMALL GREENHOUSE (*Amateur*).—A boiler and pipes form the best and cleanest mode of heating; a small stove with a flue to carry the smoke into the open air will also answer and is economical.

GREEN SLIME ON PONDS (*A Subscriber*).—Green slime has been more prevalent than usual this spring. Let off the water from your pool and scrub off the slime from the rocks with a broom, refill, and when the pool becomes clear you will have very little more trouble this season. Water snails do not appear to touch it, for we have lately been much troubled with it in a pool abounding with them. Ducks are the best scavengers for a pond, but they make clean work of flowers and weeds, so that to admit them to a pool of choice aquatics is out of the question. Notes on sub-tropical bedding will shortly be published.

LIQUID MANURE FOR TRICOLOR PELARGONIUMS (*W. G.*).—We consider sheep droppings, when they can be had, the best, one peck to thirty gallons of water. Failing the sheep droppings a peck of soot to thirty gallons of water. To impart colour to the foliage nothing does so much as exposure of the plants to light, keeping them gently growing, affording shade as that of tiffany for a few hours in the hottest part of the day. When the plants are very luxuriant, kept close, moist, and shaded, the foliage is generally badly coloured.

NAMES OF FRUITS (*Ramallo*).—1, Dumelow's Seedling; 2, Barton Free-bearing.

NAMES OF PLANTS (*E. H.*).—*Staphylea pinnata*. (*W. Hemshaw*).—*Veronica hederifolia*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE REARING OF CALVES.

THIS is a subject of considerable importance on every home farm, and the birth of a calf, always an interesting event, should be anticipated as nearly as possible to the time at which it will happen; and we will suppose, as it certainly ought to be, that a register is kept giving an account of when each cow is due to calve. There is, however, a little uncertainty as to the exact date, because it often happens the period of gestation is prolonged for a week or two on the birth of a bull calf. This fact, however, does not do away with, but rather adds to the propriety of continual attention to the cow previous to parturition, for many calves are lost and serious injury often arises when the herdsmen or other parties understanding the matter are not present at the birth of the calf. It should, however, be remembered that very few cases require the presence of a veterinary or any practised manager, because Nature provides nearly all the requisites in ordinary cases except those of wrong presentation and some others to which practical men are accustomed. As soon as the calf is born, in ordinary cases it will only require the usual attention of freeing it from the usual incumbrances; it will then be licked by the mother, during which process the cow should be milked nearly dry, leaving the calf, as soon as it rises and is firm on its feet, to suck all the remaining milk. The peculiar character and condition of the milk at this time is one of the great essentials which Nature has provided to establish the health and strength of the calf. After the successful birth of the calf it will be necessary to consider for what purpose it is to be reared and kept—whether the cow calves are to be reared for future dairy purposes, or whether together with the bull calves they are to be reared with the object of being fed and fattened for slaughter at an early age; and, on the other hand, whether the calves will be only retained to live upon the mother until they are of sufficient size and quality to be sold and killed for veal. Our subject is therefore divided into three heads or objects, and we will first speak of the calves to be reared as cows for dairy purposes.

In rearing for dairy purposes the calf may be allowed to suck

the cow and take only a small portion of the milk for several days, by the milkman taking the milk from two or three teats and then allowing the calf to take all the remainder. This, for the advantage of the cow and calf also, is especially necessary in the case of heifers with their first calf; and in their case the calves may continue to live upon the milk for ten days or a fortnight after the calves are taken away from the cows. They should have new milk fresh from the cow whilst it is warm; and to learn them to take it at first as drink the dairyman should raise the bucket of milk and introduce his two fingers into the mouth of the calf, and then dip his hand and the calf's mouth together into the milk. To induce the calf the more readily to take to drink in this way it should be kept rather short of milk at first, or rather offer the milk at longer intervals, as hunger goes far to assist any efforts made to learn the calf to drink. After the calf has learned to drink it will still require attention, for at the end of a week or ten days, instead of new milk, a mixture of new and skimmed milk may be used, and after another week or ten days the allowance may be of skimmed milk only, taking care, however, always to have it slightly heated to about the temperature of new milk. In giving the milk it will be necessary to the well-doing of the calf to prevent its swallowing the milk in a hurried and hasty manner. There are various means used to prevent their drinking too fast, particularly some recent inventions as buckets and feeders in which artificial teats are used. They are not yet in general use, and require further experience before being recommended with confidence. The advantage, however, cannot be denied of the calf's drinking slowly instead of being allowed to swallow the milk hastily without time for admixture with the saliva, otherwise calves are often reduced into low condition, with hollow sides and large bellies, and it is in this condition when so many calves are attacked by diarrhoea. In such cases, and when some calves do not take to eat so soon as they ought, we have found it answer a good purpose to give them three times a day balls about the size of a walnut composed of oatmeal and cakemeal wet up with milk. After a few times given they will eat it out of the dairyman's hand, and thus may be led to feed from hand to the trough by dropping the hand into trough with such food as it may be required to give them. There is nothing we have found so good as carrots or cabbage at the time of year, afterwards mangolds, these roots being grated and mixed with meal, and eventually chaff of either hay or straw or both in admixture. But to learn them to eat hay or green fodder it is well to tie it up in small bundles and allow it to dangle. They will, perhaps, only play with it at first, but soon learn to eat it.

We must now allude to the calf-boxes or pens, and this is oftentimes quite a primitive affair, and when not properly arranged is often the cause of ill health. We prefer to have the calves tied and kept separately for two reasons: If anything is wrong in health they can be treated individually, and when they are kept two or more in a pen they are apt to suck each other, and this often produces navel ill and is otherwise disadvantageous. We often find it recommended that pens with brick, stone, or concrete floors should be provided, and the pens washed out every now and then as occasion may require. We, however, prefer an earth floor so as to entirely absorb all the urine, and then to be littered with straw, wheat straw being best, as cleanliness requires. The straw, however, when served in trusses should be cut at the bonds with a thatcher's knife; it will then be short enough to settle down firm, and may be allowed to accumulate for a week or two especially if soft yellow sand is used and strewed over the pens upon the straw every other day. The pens will then be pure and free from that peculiar sour smell generally arising from pens whilst the calves live chiefly upon milk, and only attended to in the ordinary way, for calves void a large amount of urine, and unless it is absorbed by earth it is rarely they get either a dry bed or a healthy one. Living in an impure atmosphere is one of the most fruitful causes of disease in calves, and is often the cause of severe attacks of diarrhoea. This may, however, be produced from a variety of causes, such as the food of the cows, the food of the calves themselves, and irregular feeding with bad nursing.

Remedies may be required for the scour in calves—for instance, if the animal refuses food it should be drenched with oatmeal gruel containing a table-spoonful of tincture of rhubarb and a teaspoonful of laudanum and a little prepared chalk. It must be admitted, however, that any disease of this kind may be attributed to causes perhaps very diverse and trivial, but it may also be taken as correct that unless the cause can be ascertained the removal of the effect will be very difficult.

We cannot advise the rearing of calves at any particular time of the year in preference, having reared them in every month during the year. It generally happens that more calves are born in February, March, and April in consequence of the cows coming into profit at these times, therefore any argument we have advanced will apply with greater force in rearing calves in these months. After the calves are strong enough and healthy enough to graze in the paddocks they will still require constant attention, and it is particularly desirable that they should have a shed to resort to at night time, and that the shed should be so constructed that the animals may be shut-in at night time let the weather be ever so fine, for ours is a very treacherous climate. The shed should also be made with a floor raised at least a foot above the level of the calf paddock, and covered with 6 or 8 inches of dry earth, and littered with short straw. In this shed they should be fed with such artificial food as they are allowed, and in this also they will find a retreat from the heat of the noonday sun. Calves if they get a good bite of grass with roots and cake or meal, require little or no water until they are four months old, as the roots and grass contain so large a per-centage of moisture. Again taking into consideration the uncertainty of our climate, having white frosts at night in some seasons in almost every month in the year, the calves ought never to be out at night except on the driest of land; and then, if it happens to be a low situation near a brook or river, it may be below the fog level, in which case it is too great a risk to allow the calves to remain out at night.

In either cheese or milk-selling dairies the milk is often so valuable that after the third or fourth day from calving, when the cow's milk becomes pure, the calves are not allowed any milk at all except for a few days, when it is gradually stopped and a manufactured substitute is resorted to. In attempting to imitate milk we have no better admixture than bean or pea meal one-third portion, and best linseed cake in meal in proportion of two-thirds; these being cooked and made into gruel is best given in moderate quantities at about the temperature of milk fresh from the cow. Generally with due care and attention in all other matters the calves will do well and may be reared at a moderate cost. Many circumstances may occur to render the use of a substitute for milk either desirable or a necessity, for in case of taking a number of calves at a few days old for the purpose of rearing as dairy stock it sometimes happens that well-bred calves can be obtained from the metropolitan and provincial town markets at small cost, and large numbers are also sold from the cheese dairies, the owners not wishing to rear them. In all such cases with a little care in moderate feeding when they first arrive, we have known some capital herds raised in this way entirely by artificial means, setting the cow's milk out of the question altogether.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—In all those cases where the Lent corn has been already sown the horse labour will consist chiefly in preparing and drilling the land with mangold, also preparing the land for Swedish turnips, which ought now to be in a forward state, for strictly speaking if the land is free from couch and has been twice ploughed the less that there is done to it the better from this time until seeded, because the moisture in the land will be retained, which is so essential, particularly if at any time the weather should suddenly change to drought. Horse-hoeing the corn should now be going on if it has not already been done. In some cases where the wheat plant has lost its dark colour and looks yellow horse-hoeing is almost the only means of restoring the dark profuse colour which a healthy crop always exhibits. It is true this may be brought about generally by a liberal dressing of nitrate of soda; but there are the weeds to be considered, and if they are not destroyed they will compete with the wheat plant and seriously injure the crop. Horse-hoeing in wheat we recommend should be done with the ordinary horse hoe used for root culture, but not with the same shares; and as the ground where autumn-sown wheat is growing is sure to be hard and firm, we advise that three shares be used of the same description as the centre share commonly used for horse-hoeing between roots. These shares should be about 5 or 6 inches wide at the heel, and where the wheat has been drilled at 9 or 12 inches between the rows there is good room for the hoes to work without injuring the corn in the lines. In this way we move the ground well between three rows at one operation, and the hand hoes following will completely destroy the weeds, and the horse hoe having moved the ground an inch or two in depth will give life and renewed vigour to the plants. We find in some strong soils subject to the gold weed, and bents, charlock, &c., that it is necessary to always drill the wheat at from 10 to 12 inches apart between the lines, and in

any heavy land the horse hoe is the best means of restoring health to the plant when it has lost colour, and it must be borne in mind that a yellow and sickly plant always produces a small ear at harvest. It is, however, quite a different matter in horse-hoeing spring-sown corn, like barley or oats, particularly on sandy or gravelly soils, which are subject to poppies, charlock, marigold, and such like weeds, because where the ground is light and loose and the corn has been drilled at 8 or 9 inches apart the ordinary horse hoes made to fit the width of the corn drill will answer the purpose very well, and move the ground fairly if due care is taken to properly adjust the shares. When followed by the hand-hoeing, which is necessary in all soils subject to excess of weeds, they may with ordinary weather be destroyed, but they should be cut up when quite young, because even in the event of rain succeeding the work they will still die off. When Lent corn is drilled at sufficient width and intended to be hoed it is desirable not to sow the clover and grass seeds at the time of drilling the corn, but it is best to defer the sowing of the clover seeds until the hoeing is completed, for not only will the weeds be prevented from choking the young seeds when they vegetate but the land be fine and loose and in a good state to receive the grass seeds, which being rolled in with the ring roller will be almost sure to take and prosper. Where timber has been cut either for sale or repairs on the home farm the removal of bark, faggots, and the timber also should be removed—the sooner the better, and before the corn becomes strong and forward enough to receive injury by workmen, horses, carts, &c., passing to and fro.

The green fodder crops—such as rye, trifolium, &c.—will now be ready to cut up for the horses and other cattle, and it is a common practice that the teammen are required to cut up the green fodder for the horses under their charge after they have been out with the horses all day. It, however, often happens that an hour or two extra work is required of the horses at all the busy periods of summer, and when the teammen are required to cut the green fodder it is often made the excuse of leaving some horse labour unfinished in consequence. Our plan is to employ the odd man and odd horse in cutting green fodder, not only for cattle, pigs, &c., but likewise for the horses at the same time; by this plan we have often finished important horse labour, which would otherwise have been left over, and probably in some cases the best season lost.

Hand Labour.—The women will still be engaged in weeding the corn, grass, &c., and at times they may be employed in couching, dibbling mangold and carrots, or planting cabbages, &c. We must, however, again refer to the subject of burning couch, &c., as nothing which will rot should ever be burnt, but carted away.

BANTAMS.

We try to write for poultry fanciers of all kinds. The exhibitor, the scientific breeder, the cultivator of farm poultry for profit, have all had their turn. We will now endeavour to give some suggestions to another class of our readers, a large one we believe and hope—viz., those who have not spacious premises for model farms or poultry yards, but who delight in a few home pets, and who in some corner of a suburban garden, perchance against an end wall or under the fruit trees in some rough little orchard, keep a few fowls for amusement. What can be more charming or harmless than Bantams? They can be kept almost anywhere. It may be said they are only "a fancy" and useless for the table. This is partially true, though, putting aside the question of size, Bantam cockerels are a delicacy by no means to be despised, and are quite game-like in flavour. Bantam eggs, too, are delicious, and in the case of some breeds large for the size of the hens. They are happy in small quarters, and where insects abound find much of their own provender, so that beyond a little grain for one meal a day nothing need be bought for them. The chicks, too, do not require that incessant feeding which is necessary to get the large varieties to a good size, and are most active in catering for themselves.

As to their accommodation a little lean-to house 4 or 5 feet square will hold a dozen Bantams comfortably, and a grass yard 30 feet square, if frequently swept, can be kept in good order with this number. There should be a little gravel walk through it where they can get grit. An occasional run in the garden where they can be watched, or where no seeds have been newly sown, will be a great treat, which they will repay by picking up a multitude of noxious insects. The little hens with broods can be cooped in any snug corner of the garden; the tiny chicks can do no possible harm till they are big enough to be put into the wired run with the old birds.

Then as to the kinds to be kept. The varieties of Bantams are very many, far more than are generally known. There seems a great opening for anyone who desires to have something different to his or her neighbours in the Bantam line. Poultry shows have caused a great improvement in the beauty of certain more popular varieties of Bantams, but have, we fear, caused the neglect of others at least as useful, and which might be much improved if only equal attention were given to them. We will enumerate some of the kinds which we know to exist and then give our

ideas of the particular beauties and excellencies of each. We do not at all profess to give an exhaustive list, but only an enumeration of those which we ourselves know. Firstly come Game Bantams, the miniature Game fowl of which we know five varieties—viz., Black-breasted Red, Brown-breasted Red, Duckwing, Pile, and White; then clean-legged Rose-combed Bantam, black and white; then Sebright or Laced Bantams, with golden, pure silver, and creamy ground colour; then Booted Bantams, white black, and speckled; then Japanese, with clear yellow legs, of which we have seen four colours—viz., pure white, white with dark tails, speckled, and dark steel coloured. Then we come to the rarer sorts—the exquisite little Pekin or Cochin Bantam, a miniature Buff Cochin; Cuckoos with clean legs, both rose-combed and single-combed; Nankins, or clean-legged Buffs, both rose-combed and single-combed; Partridge; the beautiful old-fashioned Golden and Silver-spangled, now, alas! very rare (they are believed to have been much used in the production of Sebrights); and lastly, Speckled Bantams, probably of Indian origin, and of no very distinctive type. We have seen them in old-fashioned farmyards both with clean and slightly feathered legs, with lark crests and without, of plain black and white plumage, or richly intermixed with red and brown. Here we have a choice of twenty-six varieties or sub-varieties! This number might easily be increased by judicious crossing. Some years ago a then great Bantam fancier determined to attempt to produce a breed of Bantams with the Pencilled Hamburg markings. We regret that he gave up the project, for we do not think the task would be difficult. Hamburgs are a small variety, and Nankin cocks are often extremely like Golden Pencils.

Now as to the respective merits of these many kinds, where activity and high courage is admired choose Game Bantams. They must, however, have high fencing, for they are strong in wing and may fly over to the detriment of the garden. The cockerels, too, are pugnacious, but not so to the same degree as the large Game fowls. They are fairly good layers. We have enumerated the five varieties we know. These should in style all be miniature Game fowls with hard feathering and lightly clipped wings. We can see no reason why with a little pains the other varieties of Game fowl—Dun, Black, and Brassy-winged, should not be produced of Bantam size. Game Bantams are exceedingly hardy. We formerly kept them ourselves in a plantation with no house at all. Nothing ever ailed them, though they were sometimes difficult to catch. We have vivid recollections of the eve of a Crystal Palace Show; the Bantams roosted in a huge ivy-grown tree, and it was far into the night before by aid of ladders and lanterns the destined winners of third prize in a class of fifty were caught. The rage for Game Bantams was then at its height, the classes of them were enormous, and fabulous prices were given for good specimens. Fashion has now somewhat changed, though very good birds are still dear.

We must not omit to mention one drawback to Game Bantams, and, indeed, to all those varieties of Bantams which have been produced within the memory of man from fowls of ordinary size. It is extremely difficult to keep them small; a cross with an unrelated bird, or a too liberal diet, will cause a great increase of size in their produce. The very old-established breeds which doubtless were bred through countless generations by the Chinese or native Indians show little tendency to become larger. We have especially observed this difference in the two kinds of Bantams which we at present keep—viz., Black rose-combed and Nankins. The former, doubtless, have had Black Hamburg blood introduced to improve their colour and lobes. The latter are an old variety. We keep many large varieties of fowls which naturally have much bone-making food. It is impossible to keep the Bantams from getting more of this than is good for them. Year after year are we disappointed at finding our best Blacks, lovely in colour and all points desired, too large for the show pen, and then beaten by smaller birds otherwise inferior, while the Nankins with precisely the same treatment keep as small as can be desired.—C.

(To be continued.)

TOUTING JUDGES BY EXHIBITORS.

WILL you kindly permit me to say that Rabbit exhibiting is becoming very unpleasant and almost unbearable, and it is therefore time something should be done to make matters more agreeable and more satisfactory? It is well known that certain sections of the Rabbit fancy are in the habit of toutting their pet judges months before some of the show committees have even begun to move in their local societies, suggesting that Mr. A or Mr. B, or some other "National Rabbit Society Judge" should be appointed, and then they would "support him well." When exhibitors resort to this trick and succeed with getting appointments of their men then they most assuredly carry off all the prizes, and all small exhibitors, who are chiefly working men and the bone and sinew of our shows, are left out in the cold. Thus they are disheartened and disgusted; whereas if every show committee would disregard those toutters a better state of things would soon be observed.

Those "toutters" invariably suggest at the same time that the

society should offer a "points prize," and that if they could see their way clear to have one they would "support it well," because they know under their judge they would come off with flying colours, and to win points exhibitors for prizes resort to borrowing Rabbits with the object of winning the prize, that being their sole object, and not the encouraging of the breeding of good animals. This I hold is also very objectionable. The "count" for the "points prize" at Thorne is something in my opinion unprecedented in the fancy. An animal getting a first prize is to count ten points, the second eight points, and the like, so that those with bought and borrowed Rabbits of good merit pull the cards with safety, for the counts are unreasonable. It is my wish to put things on a better footing, but so long as "toutting" judges and "points prizes" continue nothing but unpleasantness can arise.—JOHN FIRTH, *Bramley, near Leeds.*

CROSS-BREEDING RABBITS.

I FIND in the *Journal of Horticulture* that "GTA" assumes that "the Silver-Fawn is now a distinct variety," and "if paired with Silver-Greys would throw them too mealy." I have bred many Silver-Fawns last year and this year, and I have yet to learn that the Silver-Fawns are a distinct variety. When I pair Fawns simply I have almost all Silver-Greys in the litters. From several experiments I had all Silver-Greys, and I have only once succeeded in obtaining two Fawns out of a litter of seven. Mr. J. H. Roberts has this week a whole litter from Fawn parents, but this is, in my opinion, the exception. I believe with Mr. McKay that the Silver-Fawns were originally produced with Silver-Greys and the Sandy warren Rabbit; and the in-breeding of the Silver-Greys, especially the light shades, they throw back to the Sandy or Fawn originals. For Silver-Fawns to be a distinct breed or rather variety they must produce offspring like themselves, but they do not do so, therefore they cannot in my opinion be a distinct variety. You may breed Silver-Fawns with judicious selection of a rich deep colour, or otherwise they will be of a mealy description. If when pairing your Silver-Greys, your object being that variety for exhibition, then you may not prove wrong; but if, on the other hand, the Fawns are your object, then you in all probability will be disappointed with the colour of the Fawn offspring.

Those who want to breed good Silver-Fawns must have Silver-Greys of the right blood as well as Fawns with which to pair, and their labours will not be in vain.

There are classes of Fawn blood which scarcely or ever would breed exhibition Fawns. I have tried the experiment myself, and I have been disappointed in every case. The *Lapin Chamois*, buff, bred at the Jardin d'Acclimatation, Paris, is identical in colour with our English Silver-Fawns, and those specimens are the products of a cross between the Silver-Grey and the *Lapin Chamois*, which is like our Belgian Hare Rabbits or our wild warren Rabbits in colour.

I have a letter from a gentleman who has a large Rabbit warren of wild Silver-Grey Rabbits, who invites me to see his Silver-Grey Meales and his Silver-Grey Sandies, which I suppose are what we should call Silver-Fawns, and he has bred them for upwards of fifty years.

It is also recorded by M. Louis Figuier that all our varieties have originated from the common wild warren Rabbit, and cites cases in natural science in support of his argument. Upon this authority and the experiments made at the Jardin d'Acclimatation, Paris, with the *Lapin Chamois*, buff, leads me finally to the conclusion that our English Silver-Fawns are strains of the *Lapin Chamois*, buff, and the first specimens ever produced (English Fawn type) were by Mr. Enoch Hutton, who years ago bred them in abundance.—JNO. FIRTH, *Belle Mount Terrace, Bramley, near Leeds.*

VARIETIES.

SPRATT'S FOOD.—We have had a specimen of Spratt's patent poultry food sent us. We have long used it, and believe it by far the best of the patent meals, and excellent when judiciously used. We have found it beneficial for fowls in any way out of condition, for those which have travelled far or been overhorned, and for hens which are backward in laying. We also recommend it for chickens during exceptionally cold weather or when they seem inclined to pine from any other cause. We do not, however, approve of their being reared on it, or on any but the simplest food as their staple diet.—C.

—THE Oxford meeting of the Bath and West of England Society and Southern Counties Association, now in the hundred and first year of its existence, will commence on June 10th, and extend over the four following days. The show yard, forty acres in extent, is situated within a convenient distance from Oxford. The cattle classes are, with a few minor exceptions, remarkably well filled, the entries numbering 324, and including 27 Devons, 35 Shorthorns, 49 Herefords, 51 Sussex, 68 Jerseys, and 34 Guernseys. Of sheep there are 242 pens, from the flocks of nearly all the best breeders in England, including H.R.H. the

Prince of Wales, and comprising amongst others 49 Southdowns, 44 Shropshires, 31 Oxfordshire Downs, 30 Cotswolds, 27 Hampshire Downs, 21 Devon Long-wools, and 19 Romney Marsh or Kent sheep. The horses number 100, and would have been much more numerous but for an unfortunate misconception as to the date of entry. Pigs are represented by 112 entries. Total of stock, 778. There are also eleven entries of butter in response to special local prizes. An interesting feature in the open judging will be the award of the Champion prizes offered by the Oxfordshire Agricultural Society. The poultry show will be the largest ever held by the Society. Of poultry there are 513 entries, and of pigeons 112, total 625. The implement department of the show will also be on a scale of great magnitude, there being 114 compartments of machinery in motion, as against 59 at Bristol and 106 last year at Bath; whilst in the shedding, nearly three miles in length, will be displayed an extensive variety of implements adapted to the various requirements of the field, the farm, and the household.

— A LINCOLNSHIRE correspondent informs us that the cereal crops in that county have never looked more promising than they do now. Wheat is strong and luxuriant, and barley is full and of an extremely good colour. The meadow lands are also in a satisfactory condition, and the general prospects of food for man and beast are better than has been seen for a long time past at this period of the year.

— We cite the following from a paper on root cultivation which was read at the Maidstone Farmers' Club by Professor Wrightson. A variation of root crops was attended with much advantage, as the constituents of the soil were thus absorbed in more equal quantities, while the farmer was further benefited by being able to supply his stock with a variety of food during a long period of the year. Those who had a succession from white turnips to Swedes and thence to mangolds, and kept up a rotation, having a variety every season, diminished the risk of a bad crop, for weather which did not suit one would perhaps be advantageous for another. There was yet another reason for cultivating a variety of crops, and that consisted in the division of labour. If a farmer attempted to grow a great breadth of Swedes or mangold wurzel alone he had a crush of work at one particular period of the year; whereas if he had a variety—if he grew mangolds, kohlrabi, Swedes, white and yellow turnips, and cabbages—the labour would be distributed over a long period of the year. If, therefore, they took into account the advantage of the change of food for their stock, the better preparation of the land for the succeeding crop, and the division of labour, they found a very good reason for cultivating roots in greater variety.

— WRITING in the *Mark Lane Express* on fangy bulbs Mr. J. J. Mechi observes:—In rich and free soil or highly manured land fibres are multiplied, and a single tap root does the needful; but where the plant food is widely and sparsely distributed bulbs will send out powerful fangs in search of it. When I impoverished my surface soil by steam-ploughing it very deeply, and mixing it with a large quantity of poor and unaired subsoil, the plums in the pudding were too far apart, and the mangolds knew it, and accordingly sent out searchers in the form of long and thick fangs, which brought to their parent the good things which were widely diffused. Feeble-rooted plants could not have done this. I must protest against the supposition that these fanged mangolds are of inferior quality. On the contrary they are dense and heavy, and keep well, and have the advantage of having buried their bulbs deeply in the soil, which is always a sign of quality either in turnip or mangold. A turnip in deep rich land will send a single tap root a yard or more deep, but not so on poor, shallow, or ill-cultivated and undrained land.

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

No. 6.

THERE is no respect, perhaps, in which the bar-framist excels the straw-skepiest more than in the ease and certainty of success with which all his swarming operations are managed, for I must in this paper suppose the object of the bee-keeper to be an increase of stock.

If natural swarming were always successful instead of involving continual disappointment and heavy loss from inconvenience of time and place of swarming and the risk of swarms disappearing, I believe nothing would be better in the long run than to leave bees to settle their colonising arrangements in their own way. When the swarm comes off at the right moment and pitches in the right place there is not only no difficulty whatever, but I believe no artificial swarm, however excellently managed, comes up to that which issues naturally under the circumstances described; and for my own part I must confess that when I am at home and circumstances are favourable for watching and hiving, I generally let my bees follow the instincts and guidance of Nature. Of late years I have usually been very much fixed at home during the whole swarming season, at least up to the end of June; so I trust mostly to the chapter of accidents, and it is seldom I have to lament the loss of a swarm. But it is very different in other cases where the loss would be the rule, as where

the bee-master is absent from home the greater part of the day, or so tied when there as to be practically out of call. Here artificial swarming becomes in a measure necessary.

Of course it is practicable to force bees to swarm out of common straw hives or boxes. This is done either by drumming-out the whole population, or extracting one or more brood combs and operating with them. I have tried both many times and with more or less success. But there are difficulties connected with both methods which require a very practised hand, and then they involve a great deal of risk and trouble, so much so that I never now practise either of these modes of making artificial swarms. A third plan I still frequently adopt which involves next to no trouble or risk. This is adopted whenever the queen of a populous and thriving stock is observed and caught in a super. Nothing is easier than to make her at once the mother of a swarm. Adjust the super (if a small one) over a suitable stock hive or box with or without bar-frames, if with comb so much the better; shift the parent hive to some distance and replace it by the newly-prepared hive and the thing is done. The better plan of proceeding is to secure the queen in a glass with a few bees and give her to the hive after the change of hives has been made, and when the bees have been for some minutes in anxious search for her. Nor is it advisable to perform this operation at all except on a fine day when large numbers of bees are abroad. One caution must be given here: Let the parent hive should become too much thinned of its adult population, as will often be the case when they have discovered the loss of their queen, it is good policy to close the entrance of the hive from dark to dark for a whole twenty-four hours, taking care to give ample ventilation to the hive. In the meanwhile they will have become reconciled to the loss of their queen and will mostly stay at home. From inattention to this precaution much valuable brood has in cases of this kind perished, and the hive even failed to rear a young queen. Of course, the removed hive will have to be watched when the young queens that will be artificially reared therein are approaching maturity, so as to secure the casts or prevent their swarming. There can be no doubt that of all methods of artificial swarming this is the simplest, and with proper care the most certain of success.

But where bar-framed hives are in use there is hardly more trouble or risk, and here of course the time for operating is wholly under the control of the bee-master. It is advisable to allow the stock to arrive at its full maturity short of the bees being largely at work in supers; then, choosing a fine still day when the bees are at their busiest, and all being ready to hand, we would commence operations as follows: With the least disturbance remove all coverings, blow a little smoke if necessary among the exposed combs, and proceed to take out frame after frame, commencing at right or left as is most convenient or where it is believed the brood is mostly situated. Each frame as it is taken out should be very carefully examined to find the queen. It is advisable that she should not be removed from the parent hive. Selecting therefore at least a couple of combs containing eggs and brood of all ages in sealed and open cells, let them be carefully adjusted in the centre of the new hive, which should be filled up with as much worker comb in the bar-frames as can be supplied. Large pieces of artificial comb-foundation would well repay the outlay upon them. When all is ready (it being certainly ascertained that the queen remains in the old hive) put the new hive on the old stance and shift the parent stock to a distant position. Here again you have your swarm secured with very little trouble.

If on examining the combs of the old hive royal cells be found tenanted with brood, of course use can be made of them. The most forward of such cells with their bar-frame entire should be given to the newly formed stock: three or four would suffice. We always like to have several such cells in case of possible accident or failure in maturity. If any more are found they may either be cut away and destroyed, or else they can be utilised for the formation of other swarms, if desired, on the same principle. It would be better, however, not to weaken the old stock by removing any more bar-frames than those taken out in the first instance. We should cut out the royal cells and introduce them into the middle of a comb taken from some other hive, which could then be treated as before indicated. In the case of such royal cells utilised as in this instance and in that first described there would be some difference probably in the result. In the first instance, the new hive being only partially filled with comb and brood, there would be little probability of the issue of casts; but where inserted in a full hive a swarm must be expected, and with the more certainty at the proper time. Should any such cast or swarm issue it would be advisable to return it after securing its queen and destroying her, and so to treat any other casts which might follow.—B. & W.

BEES.

MUCH has been written in favour of wooden boxes instead of the old straw hives. I may say that although my present situation is not one at all favourable to the keeping of bees, yet on the 2nd of May we had a swarm from an old straw hive which

promises to do well. We had only two old hives, and had only obtained these in March, but with a little feeding they have done pretty well; and as I never before remember having had a swarm so early I forward the information to you. I may add that the site they occupy is upwards of 400 feet above sea level, with no higher ground for some miles around us. Have any of your correspondents with better means and better positions been earlier than the above? I think I have heard of a swarm of bees in April, but it is a long time ago, and I am not certain that it could be verified. One other inquiry I would like to make, Are bees better managed now-a-days than they were fifty years ago? My memory carries me back to 1826, when honey was more plentiful than I have ever known it since, and at that time was in some places substituted for sugar for many domestic uses. Will it ever be so again?—J. ROBSON, *Coxheath*.

LIGURIANISING.

"I SHOULD be greatly obliged," writes a correspondent (Mr. J. H.), "if one or other of your experienced bee-keepers would kindly state the best mode of putting Ligurian queens to swarms of common bees. The idea I have is to catch the queen as she leaves the hive with the swarm, let the swarm settle, and then put the Ligurian queen to the swarm before hiving it; but as I intend trying to cultivate Ligurian bees, would like some of your writers to give me their experience so that my experiments may be successful."

Our correspondent's plan, as stated above, could not be successfully practised. It requires much patience to wait and watch for bees swarming, and also much courage and dexterity to catch a queen in the act of swarming. Besides, the rush and gush of bees in swarming are so great that the most expert and experienced person in the world could not be certain of seeing the queen in first swarms as they issue from their hives. If a queen does not go with a swarm the bees soon know it and therefore will not settle. They have a language of their own, and the tidings of their loss or misfortune go like a telegram. And experience does not support the idea of giving a queen to bees before they are aware that their own has been lost or taken from them. When bees find and feel that they are bereft of their queen they will receive and welcome a stranger, even a foreigner, to take her place if properly introduced. This idea of felt bereavement should be well understood by all who mean to ligurianise their apiaries.

Instead of the proposal of our correspondent to catch the black queen in swarming I suggest the most safe and profitable of all plans of introducing Ligurian queens to black bees. After swarming, say the first day after first swarms have left, give Ligurian queens to the old stocks or mother hives, for then they are without queens and royal regency; and though the bees have three or four eggs or maggots in royal cells, they will readily accept queens carefully introduced, and pregnant queens introduced to such hives are worth more than the cost of them, for they begin laying at once, whereas the eggs or maggots would not become perfect and pregnant queens for about a fortnight or more. In artificial swarming the old queen is generally removed with the swarm before eggs are set in royal cells. The bees of the old hive soon discover that they have lost their queen and begin to search for her. During the time of their trouble and concernment they will receive a strange queen if given to them, and never attempt to set eggs in royal cells. "But cannot the queen be given to the swarm as well as to the old hive?" Yes, but it is more difficult and dangerous to do it, and not so profitable or certain of success. In natural swarming the old queen goes with the swarm, and in artificial swarming proper the old queen should go with the swarm. It is unnatural and bewildering to put a swarm of bees into an empty hive and then give them a strange queen or a few pieces of comb containing eggs from which it is expected the bees will rear a queen. In changing queens of hives very little should be left to hazard. If we go too far or too fast in this work we put ourselves in the hands of chance, and thus expose ourselves to disappointment and loss. If our correspondent has many stocks to ligurianise this year we advise him to take from his earliest stocks their queens as soon as possible, and in about twenty-four hours after the queens have been removed put Ligurian queens in their places. This should be done at least a week before swarming. Thus his first early swarms will have Ligurian queens, and the mother hives will have three or four young Ligurian queens each in royal cells, which could be easily cut out and given to later swarms. It would be no difficult undertaking to ligurianise twenty stocks of bees this season from a single fertile Ligurian queen. In removing a fertile queen from a hive whose combs are covered with bees they set from three to six eggs in royal cells, and thus create far more queens than they really want.

The mode of introducing perfect queens to hives has now to be noticed. It is generally done by putting them in cages made for the purpose, and placing these cages between the combs amongst the bees for some hours or days, and then letting them out. The queens thus caged and placed catch the odour of the community and become naturalised, and the bees become at one with them before they are set at liberty. When the principle of ligurianising

is understood the practice becomes easy and successful in more ways than one. The price of a Woodbury hive is 21s. or thereabouts.—A. PETTIGREW.

OUR LETTER BOX.

RED-FACED SPANISH FOWL.—Mr. F. Parker, 8, Milk Street, London, asks for "A WESTERN SUBSCRIBER'S" address.

FLIES IN FOWL HOUSE (A. M.).—We know well how great is the nuisance of which you complain. We have never known carbolic to fail. In our own houses we use the carbolic acid soap. We make it into a thick lather, and with a brush put it freely on every wall. The mere whitewashing by flapping the brush backwards and forwards is useless. It is necessary to introduce it into every crack and cranny. All the woodwork should be served the same, even the perches. While the fowls are out let the flooring of the house be well wetted with a strong mixture of lime and water. After it has laid an hour let the house be swept out with a hard broom till it is scrupulously clean. This must be done after the walls, &c., have been washed. It is, however, possible the fowls bring their plagues with them. If they do it is for want of a dust bath, or from their frequenting some of those outhouses that seem to be left as feeders and nurseries. If the latter be the case either lock them out or destroy the pest house. While the house is cleaning keep the fowls out of it. They will get as near to the entrance as possible. Provide a heap of ashes and road grit, mix therewith a pound of black sulphur. The fowls will use it to their great comfort. If you have convenience for it keep the fowls out of their house for three or four days, and let the cleansing be repeated daily. If these instructions are carried out you will get rid of the pests. While subject to this visitation fowls do nothing profitably.

CHICKENS' DISTENDED CROPS (J. S. W. O.).—Give a teaspoonful of gin for two or three mornings following.

REMARKS.

- 8th.—Rainy until about 10 A.M., the rest of the day dull with occasional sunshine; evening fine and bright.
9th.—Fine morning, heavy clouds and very dull in the middle of the day; fine afternoon and evening. (light night).
10th.—Bright warm day, rather cloudy at times, still easterly wind; moon.
11th.—Wet morning, but cleared after 10 A.M., fine the rest of the day. Lunar
12th.—Very fine warm day, heavy clouds at 9 P.M. (halo 10.10 P.M.).
13th.—Wet morning, fine during the middle of the day, very heavy shower at 5 P.M.; fine evening.
14th.—Fine day, gusty wind.
Temperature much the same as last week. Sunday might almost be called a summer day.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 15.

THERE has been a decided improvement in our Market the last few days, and clearances have been more readily effected. Among new fruits Cherries and Apricots are reaching us from France and Spain. Outdoor vegetables are in good supply.

From observations taken near London during forty-three years, the average day temperature of the week is 67.1°; and its night temperature 44.3°.

TEA ROSES.

THE manner of growing these, the only Roses worth calling "perpetual," is destined to undergo a revolution. There has of late years been a great move towards growing, flowering, and finishing with plants in pots in one season—for instance, Fuchsias, Gardenias, Tree Carnations, and many others of less importance—but till within a year or two I had no idea that Tea Roses were amenable to this style of culture. It is, however, proved that they are not only amenable to it, but that grown in any other way they will bear no comparison at all. Our young beaux will have to look elsewhere for a supply for their button-holes, for Catherine Mermet and Souvenir d'un Ami 5 or 6 inches across will be voted vulgar in the extreme; even in the bud just showing colour they almost look like miniature "Sugar-loaf" Cabbages. Happily our ladies do not object to large Roses, even should they be able to bury their faces in them; therefore I am on the side of the ladies (the next best position to that enjoyed by Mr. Disraeli when he said he was "on the side of the angels"), and shall listen to no one who decries large Roses, unless they are at the same time either coarse or scentless; for remember the words "large" and "coarse" are not synonymous.

Anyone who has noticed the natural mode of growth of Tea Roses will have observed that to thrive at all well they must throw up a continual succession of suckers, first weakly, then a little stronger, and afterwards, if encouraged, stronger still. This, then, is the key to the only right way of growing them, and to make sure that all the suckers shall be of the right sort it is necessary to have the plants on their own roots. I know no reason for growing them on Briars or Manettis; it cannot be to make them grow stronger, for it has the very opposite effect in the long run. It cannot be to enable them to withstand winter, because if they are killed down to the ground all is gone but the Briar, whereas Tea Roses on their natural roots down in the ground a foot or two would probably start again from the base in the spring. Nor is it because they are difficult to propagate, for they are as easy to strike as Verbenas. If it is argued that it makes them more floriferous, then remember that, with the exception of one or two sorts not strictly Teas, where there is growth flower will follow as a matter of course, and the finest flowers do not come on the weakest growth.

In July, 1876, I inserted cuttings of the best sorts I then had, including some which are not yet surpassed—viz., Devoniensis, Alba rosea, Catherine Mermet, and Souvenir d'un Ami. The cuttings were made of the firmest growth of the current year, and placed under handlights on the north side of a wall. They soon rooted and started growing without losing much of their old foliage; they were then potted into 4-inch pots, placed in a cold frame kept rather close and shaded till they started, then gradually hardened, and soon after—probably in September—they were shifted into 8-inch pots and placed outside. They

were protected a little during winter, being in a cold house not by any means frost-proof, and during last summer were repotted into 14 and 15-inch pots, using soil such as would grow fruit trees well in pots—viz., fresh rather heavy turfy loam, a sprinkling of half-inch boiled bones, a few pieces of charcoal, and a little decayed farmyard manure of good quality dried and rubbed through a sieve. The loam was rough, many of the pieces being half the size of a brick.

This spring we have had flowers such as I never saw before, and the plants have kept constantly throwing up suckers stronger and stronger, with flowers to correspond. But the pots are already too small for the plants; they will therefore be transferred to the open ground on the north side of the walls of some of the houses, and be succeeded by a fresh batch. It will be seen that the plants now to be turned out are nearly two years old; but from past experience I have no doubt of being able to do them nearly as well, if not quite so large, in one year.

It may be said that the same liberal treatment given to plants not on their own roots might have produced equally satisfactory results, but I can say decidedly No; for I bought some of the best plants procurable, and treated them as well as I was able, and they are simply nowhere in comparison.

Mildew does not often come spontaneously on plants grown thus without a check, but the purchased plants of newer sorts had some and it spread to the others. When such a case occurs I practise and advise no half measures, but gather all expanding flowers, place some sulphur with water in a waterpot, stir well about, and apply with a syringe in fine spray to both sides of every leaf in the house whether affected or not, and the first time the sun shines on it every spore will be killed. This is much easier and a far more effectual plan than dusting. The sulphur can be syringed off in a day or two, leaving hardly a trace behind. I do not think sulphur does much good in dull weather either inside or out; it is not at all easy to kill mildew outside in autumn when the sun has but little power.

So much for Tea Roses indoors. I have said that the plants in pots now will be turned out against the north side of some of the houses. I am fully convinced that Tea Roses do not like extreme temperatures. A south wall is the very worst possible position for them, but the north side of a heated house suits them to perfection. I have all such positions almost covered with them, but some of the sorts will have to give place to their superiors. I should advise friends in a less genial climate to try their Roses on the western or south-western side of a building. Mere garden walls will not do so well as the walls of a building.

Tobacco powder is very useful for dusting whenever there is a suspicion of fly. It is certain death to the fly with which it comes in contact, and if applied in the evening when the sun is not powerful it will not injure the foliage even if allowed to remain on next day. Dusted over cuttings closely confined in a handlight or bellglass it will kill every insect whether it touches them or not, but in this case the sun must on no account touch it. The powder I use is prepared by Corry & Soper, London,

and is supplied by nurserymen; but I believe there are other manufacturers equally to be depended on. It is free of duty, and therefore costs little.—WILLIAM TAYLOR.

VEGETABLE CULTURE.

CHAP. XIX.—PARSLEY.

PARSLEY is always an important crop in the kitchen garden. It is one of those herbs which every person tries to grow, but unfortunately not always with success. Indeed there are few crops more difficult to manage in some gardens; in others it is quite the opposite. Canker and grubs are its greatest enemies, and in this case as well as in many others prevention is better than cure. Very often the young plants come up freely at first and die quickly away afterwards. When they begin to go it is difficult to stop the destruction. Many things have been advised to do this, but I never knew one of them to succeed in all instances.

To ensure healthy growth provision must be made for it before the seed is sown. In selecting a piece of ground for Parsley culture it should be moderately heavy soil, not too warm and gravelly, nor much exposed to the sun. Before digging it over, soot, lime, and wood ashes in equal quantities should be spread over the ground 3 inches deep and worked well in with the soil. This will make it vermin-proof for twelve months, and the Parsley will grow unmolested so far as the grubs are concerned. This will always be found a much safer plan than applying a dose of any insecticide after the plants are up and beginning to go off. A little salt is very good for mixing with the soot. Every person can get soot, and nothing better can be applied.

As Parsley should always be sown on ground that has been well manured for the previous crop no more manure should be given when the Parsley preparation is going on.

The earliest sowing should be in March, again in April, and the last at the end of May or beginning of June. Where only one sowing is made in the year it should be done at the last-named time. Parsley sown now will remain perfectly good until this time next year or longer, but that sown in March generally runs to seed early the following spring; therefore to depend on this sowing would leave a gap in the supply during the spring months when it is often most wanted. It is always best to sow the seed in drills. Sometimes a long row can be sown along the bottom of a wall or by the side of a path; but where a large quantity of it is grown it is best to make a large patch of it together, and then the rows should be 15 or 18 inches apart. About 1½ inch is the right depth for the drills, and the material used for covering over the seed should be half soil and half lime, soot and ashes mixed together. This is another excellent precaution both for grub and canker, and it cannot be too carefully attended to. As soon as the rows can be seen the hoe must be put to work amongst them. When the plants are 3 inches high they may be thinned out to about the same distance apart, and when they are in extra strong health they may be left double this width; but when there is any suspicion or indication of the crop dying off the thinning should be delayed, or the crop may become deficient. When the plants have fairly met in the rows and becoming crowded all the large leaves should be gathered as they become too coarse for use. After giving a supply all winter the whole of the leaves may be cut off close to the ground, and when the plants sprout again the produce will be as fine as ever, especially if a little soot is washed down about the roots at the time of cutting it over.

Myatt's Garnishing is an old favourite sort of ours which we always grow in quantity, and Carter's New Fern-leaved is worth growing on account of its ornamental character.—A KITCHEN GARDENER.

AURICULAS.

To all admirers of this long-neglected flower it is quite refreshing to read the reports of the late Crystal Palace and Manchester Shows. It would still be a greater treat to have seen either or both of the Exhibitions, and I would respectfully suggest to our English brother florists the advisability of holding a show near the borders so as to give an opportunity to us Scotch growers, if not to enter the field as competitors, at least to enjoy the pleasure of seeing our favourites in perfection as well as to compare friendly notes.

I was much struck with an observation I read lately as to the difficulties experienced in growing or rather blooming the

Auricula in large towns such as Sheffield, where one has to contend with the effects of smoke and bad air, &c., and the plan taken to try and overcome this great drawback. There is no doubt the Auricula, like all other florist flowers, always thrives best when it enjoys a constant circulation of pure air. As an instance of this, my old and much-respected friend, that veteran raiser and grower, the late George Lightbody, was in the habit of complaining very much of the bad effects on all his plants caused by the fumes and smoke of an adjoining gas works. This was specially observable on Auriculas of a delicate habit of growth, and having noticed that any plants he had from me were generally very vigorous and healthy, he was latterly in the habit of sending me some delicate growers to see if pure air would impart more vigour into them. The only one I failed with was a most exquisite grey-edge called Traill's Earl of Dundonald, and in sending me a very small plant the second time Mr. Lightbody wrote that he believed it to be the last bit of it in existence.

My father (a keen florist, now gone to his rest) both grew and competed successfully with the Auricula in Perthshire upwards of sixty years ago, and at that time he said it was quite the rage. I do not see any reason why this lovely hardy plant should not again become the "flower of the day."—J. M.

GLOXINIAS.

ON page 377 a dozen varieties of excellent Gloxinias were enumerated, which, if well grown, cannot fail to give satisfaction to the cultivators. There may, however, be some difficulty in obtaining some of the varieties named, and a similar number are now submitted which are not only obtainable, but which for distinctness of colour and sterling merit will be difficult to excel. They are selected from a splendid collection now flowering in Messrs. Veitch's nursery at Chelsea. This firm has during recent years devoted special attention to improving this valuable summer decorative flower, and under the skilful manipulation of Mr. West, in whose charge the plants are, many varieties of great excellence have been raised. The whole of those now selected are, however, not the productions of the firm; one or two of them are of continental origin, and the best white was raised by Mr. Rapley, the grower of the fine collection of Calceolarias referred to on page 356, and was distributed by Mr. B. S. Williams; yet most of the varieties now submitted were raised in the renowned Chelsea establishment, and they are selected because of their dissimilarity to each other and their general superiority. Those who grow the varieties now named and grow them well, which is not difficult to do, will not be disappointed.

It may be remarked that many of the finest flowers have the corolla divided into six and occasionally seven segments, the normal number being five. The additional segment is a great acquisition by imparting to the flower a smoothness and roundness of form not possessed by the five-lobed flowers. Continental raisers claim the honour of having first produced the additional segment, and perhaps the claim is a just one; but the matter is just about as doubtful as to who was the real discoverer of the planet Neptune, Adams in England or Leverrier in France. Sagés differ on both points. As to the Gloxinias, however, it is not only certain that several of the Chelsea-raised flowers have more than five segments, but it is equally certain that Avalanche raised by Mr. Rapley has invariably six lobes.

Since Gloxinias have been so greatly improved of late years, and since their flowers are so varied in colour and so beautiful, also considering that the plants in consequence of their expansive foliage and its liability to injury are not the best of travellers, it becomes a question whether cut flowers should not be staged at exhibitions. The varieties are surely as worthy of being so exhibited as cut blooms of zonal Pelargoniums. One thing is clear—namely, that the individual flowers of superior Gloxinias will bear close and critical examination. The clear and chaste spotting of some of the flowers and the fine contrasting colours of others, the spotless purity of the white and the richness of the warmer colours, render them not only conspicuous but singularly attractive; they also keep very well in water—better, in fact, than some other flowers that are shown in a cut state.

All the varieties now enumerated have upright flowers:—*Mr. Gladstone*.—Throat very pure, base of segments purplish crimson, body shading to rose; fine habit, stately and free. A splendid variety.

Niobe.—Rosy crimson edged white. Very pretty and effective.

Nimbo Cileste.—Crimson; throat densely spotted with white. Very attractive.

Charme de Lutesco.—White ground densely spotted and shaded lilac. Distinct.

Roselane.—Rosey purple throat, crimson at the mouth, segments margined with white; fine habit, free, and very good.

Coupe d'Hébé.—Pure white throat; body colour brilliant crimson scarlet blotched with purple. A splendid variety.

Avalanche.—The finest of all the whites, but the throat faintly mottled. Large and of superior form.

No Plus Ultra.—Dense purple, base of throat white. A telling variety; large and very fine.

Vesuvius.—Bright glowing scarlet, white throat. Very rich and striking.

Conquest.—Magenta shaded purple throat internally, outside white; white margin. Very fine.

Eclipse.—Very rich velvety crimson, faint rose margin. Best in its colour.

Rebecca.—Creamy white throat, colour purplish crimson shaded rose, centre of each lobe white. Stately and fine.

The above twelve varieties are selected for an extensive and unique collection of these beautiful flowers.—J. W.

NOTES ON THE RASPBERRY.

SOME remarks having recently been made by different writers about Raspberries being all the better for being left undisturbed for a great number of years, and as this fruit forms an important item of cultivation in the immediate neighbourhood in which I am residing, I may be supposed to give an opinion backed by extensive practice. First of all I may say, that although it would not be difficult to find a piece of Hops that has existed as a cultivated garden producing good or fair crops according to the character of the respective seasons for one hundred years or more, and possibly may continue doing so for an indefinite time, I am not aware of any plot of Raspberries anything like so old; in fact, I believe it would be difficult to find a piece more than twenty years old. The general opinion in this district is that Raspberries, like all other fruits, only continue to bear a certain number of years with advantage and profit; the plants will continue to exist, but not to bear fruit in sufficient quantity and quality to pay for the ground they occupy. This practical mode of judging of the time to make a change in the cropping is one which no one is more likely to exercise than those whose living depends on what they gain by occupying the land. When a permanently established crop like that of Raspberries is destroyed or done away with we may rest assured that it is no longer worth retaining.

Presuming that someone will be glad to know how this fruit is cultivated on an extensive scale in Kent, it is necessary first to glance at the character of the soil. This may be roughly described as being a dry one, water for domestic use being rarely found at a less depth than 100 feet. Stones of all sizes from the very smallest to those weighing a hundredweight or more are plentifully interspersed with the top soil, but the larger stones have in most cases been removed; but it is not thought good practice to pick off more than will work-in reasonably well with the plough or spade. The stones are of a hard kind, though not at all approaching flint, but they make good roads. The soil which is mixed with these stones, although some crops thrive in it very well, has the character of being a hungry poor one, and, in accordance with the popular notion, requires a shower of rain every day and a thorough wet day on Sundays. Yet nowhere in the kingdom have I seen such good hedges, it being the boast of some farmers that a hare inside some of their fields could not get out except at the gates. Some trees also thrive remarkably well, Sweet Chestnuts notably so, but grass and most small crops require feeding. Fruits that seem to thrive best of all are Damsons, Red Currants, and Raspberries. Gooseberries are also grown on a large scale, but are declining in favour, and only a few Black Currants are grown. Excellent Morello Cherries are grown, and a fair proportion of Apples, though neither in quantity nor quality equal to those grown in some other parts of the county. Plums of most kinds like a deeper and moister soil, and Pears are not much grown; but as Raspberries are more especially regarded, and as some growers send two or three tons or more to market every year, it may be interesting to know their mode of cultivation.

This is very simple and easily explained. In a general way this fruit is cultivated in connection with some other. Usually

Damson trees in the form of standards 6 feet high are planted all over the ground at about 24 or 30 feet apart, these trees being staked carefully for a few years and compact heads formed by looking them over every winter and pruning them a little. Raspberry canes are then planted over the ground in rows 5 or 6 feet apart. If the latter distance the canes are afterwards allowed to form a continuous row, but if only 5 feet is allowed the stools are about the same apart in the row. The winter pruning consists of cutting the young canes all to a uniform height of about 2½ feet, no stakes being used. From conversations I have had with several growers they seem averse to adopt the plan, common in private gardens, of allowing a greater length of cane and not cutting off the upper portion with its cluster of buds, as they affirm that by this plan they get a longer succession of fruit, and, moreover, if it all came on at once they would have difficulty in getting it picked, for, as it is, the labour required in picking say 300 or 400 lbs. of Raspberries daily is a serious matter. Moreover, by the canes being cut in the way described the sun shines into the middle of the bush or head, and excellent fruit is obtained. From this neighbourhood the fruit is sent to market in tubs with something tied over their tops. This, of course, necessitates a heavier carriage to be paid, and taken in addition to the cost of picking, has limited the growth of this fruit very much. Still it ranks as one of the most important items of cultivation just around where I am now writing, and, in conjunction with Damsons, occupies a much wider area than that of Wheat or any other farming crop. Of the next important fruit grown, Red Currants, I may perhaps have something to say hereafter, but would like to be better informed of the various kinds grown before I do so. I may, however, observe that I fear many of our Raspberry growers are rather careless on this score, although others keep pace with the most fastidious private growers in this respect and grow all the kinds known to be good.

As someone said that age increased the fruit-bearing properties of the Raspberry plant, I may add that after a certain lapse of time quite the contrary is the case. Of course heavy and copious manuring will tell its tale, but like all other fruits the Raspberry will wear out. In the cases described above the advancing growth of the standard Damson renders the Raspberries gradually less fruitful, and they are removed by degrees and the Damsons are allowed to occupy the whole space. Some plantations that are solely Raspberries also wear out; in fact what is there in vegetation that does not do so? And to point to a piece of wild plantation bears very little on the case, for in such a position it only obeys the laws of Nature, and if possessed of vital powers sufficient to drive away a previous occupant of the spot it does so. Nettles and Docks do the same thing, and in their turn have to make room for timber trees and the like; but in the matter of Raspberries the question ought to be narrowed in the plain practical one, Is it advisable to allow the Raspberries to occupy the same ground for a whole lifetime or more, or is it better to change the site? Surely those having a due regard to the *£ s. d.* part of the matter have the best right to give a judgment on the affair.

I will possibly at a future time call attention to the merits of a Damson widely cultivated in the district; and as its originator lives in the same parish in which I reside I hope to obtain some information on its early culture from my worthy old friend, from whom many more years of its culture can hardly be expected, as he is fast approaching the completion of his eighty-seventh year.—J. ROBSON.

GEUM COCCINEUM FLORE-PLENO.

OF all hardy border plants this is one of the earliest, brightest, and finest. It is not really a double flower, but at the first glance has the appearance of one, and almost resembles a miniature Turban Ranunculus. The finest display of this Geum—indeed one of the brightest beds of any flower that I have seen at this early period of the year—is in the nurseries of Messrs. Rolleston at Tooting.

The plants were raised from seed sown last year, and were planted in rows about a foot apart on a border having an east aspect—that is, a border in front of the western boundary wall of the nursery. The plants in this bed commenced flowering in March, and have been yielding a valuable supply of cut flowers throughout the spring. The beds are now a mass of scarlet; not a dense close mass like that produced by a bed of scarlet Geraniums, but throw up in great profusion spikes of

double scarlet flowers totally dissimilar from any other flower of the same period. Plants raised in this manner and treated as biennials are immeasurably superior to plants left year after year in borders to produce straggling spikes of small semi-double flowers.

The plants in Messrs. Rollisson's nursery are about a foot high, and the spikes do not need stakes to support them.

BRIDGE HALL, BURY.

THE SEAT OF O. O. WRIGLEY, ESQ.

ALL who have visited the great Whitsuntide shows at Old Trafford, Manchester, or who were present at the grand exhibition held during the first year of the Westminster Aquarium, have no need to be told of the excellence of the Orchids and Ferns which have their home at Bridge Hall; but they may be not unwilling to know a little concerning them in their ordinary condition when not seen in their "company manners," and to them as well as others these brief notes of a recent visit there may not be unwelcome.

A few years ago a very dear friend who was quartered then at Bury, but who is now, like another Cincinnatus, growing his Cabbages in Natal, sent me at the head of a letter a sketch of the country round Bury. It consisted simply of a long row of chimneys vomiting out volumes of smoke. If that be somewhat of an exaggeration yet it is not to a southerner a pleasant land. From Manchester you pass through a series of towns, in all of which smoke, dust, and factory refuse attest to the increase of wealth, but certainly not to rural delights; and as you approach Bury it does not improve. Trees battle for existence; shrubs are sickly; streams not certainly free from pollution, and reminding one more of the yellow Tiber as I have seen it after a tremendous rainfall than anything else, are all evidences that one must not look for the perfection of outdoor gardening in these localities, and it is this, amongst other things, which has been probably the cause of such spirited cultivation of Orchids and stove plants in these manufacturing districts. Glass protects them from the atmospheric influences so destructive to out-of-door culture. Coal is plentiful, purses are long, and the rivalry which has led to such splendid results in manufactures has tended to produce similar success in Orchid culture, and nowhere are finer masses of the very best Orchids to be seen than in the north.

Bridge Hall is a plain and unpretending but most comfortable house, the outdoor gardening of little importance, but with a great wealth of beauty and high cultivation under glass. These glass structures are not built for ornament but for use. There are no high-domed conservatories, but good healthy homes for the plants, which are dear to the owner and most skilfully cultivated by his very able and enthusiastic gardener Mr. Hubbersty. The *Gleichenias* were in splendid condition, and I was very much surprised to find that one plant of *flabellata* had been in the same pot for nine years and yet was throwing up grand fronds. *Gleichenia rupestris glaucescens* was also very fine, as indeed were the various plants of this fine genus grown here.

Orchids are grown here as cool as it is allowable for them to be, and amply repay the treatment. Taking the *Odontoglossum*, that varied and beautiful genus, there were grand masses of *Alexandrae* (*Bluntii* or *crispum*) with the varied markings it exhibits; *O. triumphans* very fine; and *vexillarium* in such vigour that I hope when in flower it may be seen by many, so as to gladden their eyes with a fine specimen of one of the most lovely Orchids in cultivation, and in such condition as it is not often seen in. The collection is unusually rich in *Masdevallias*. There is a splendid variety of *M. ignea*, one of the very highest coloured ones I have ever seen, and another of *M. Harryana sanguinea*, of most intense glowing scarlet. Then there is the curious *M. chimæra*, fine clumps also of *M. Lindeni*, *M. towarensis* in great numbers, and another botanical curiosity, *M. nycterinia*. The *Anguloas* exhibited by Mr. Wrigley have always been particularly striking, and the grand masses of *Anguloa Clowesii* with forty or fifty growths now coming into bloom will be indeed a sight. Then *Anguloa eburnea* was also in great vigour. Among the Orchids one is in the habit of seeing in great beauty about Manchester is *Dendrobium Falconeri*, and at Bridge Hall there are several fine plants of it. The *Thunias* are also very well done here, and fine masses of *Bensoniæ* promised for vigour and abundant bloom. *Cœlogyne cristata* was also numerous and well grown and is a great favourite. In fact one has only to run through the most select Orchid catalogue, and to find that, in whatever

section it may be, healthy and vigorous masses are to be found here. No, there is one exception: by no inducement can *Phalænopsis Schilleriana* be coaxed to grow. In every aspect, condition of temperature, and mode of culture it has been attempted, and in every instance it has failed.

Amongst other plants cultivated here with great success are the *Nepenthes*, to which a house is principally devoted; and here were to be found grand plants of *Nepenthes Hookeriana*, which, although considered only a variety of *N. Rafflesiana*, has quite distinct pitchers from it. They are 3 or 4 inches long and the growth is more compact, while the lid of the pitcher turns back instead of, as in *Rafflesiana*, turning over it. Then there is *Nepenthes sanguinea*, the finest of all the family, with pitchers from 8 to 12 inches in length and 3 inches in diameter, and their deep crimson colour is sure to attract. Then there is the lanata variety of *Veitchii*, with large pitchers 8 or 9 inches long and leathery leaves; the pitchers are green and covered with minute woolly hairs. Other varieties of *Nepenthes* are cultivated, but these struck me as being particularly fine.

Noticeable also were the grand masses of *Anthurium Schertzerianum* with so many variations of form and size, some with long, others with broad spathes, and one in which it is almost horizontal instead of perpendicular. There was a number of other noticeable plants; indeed I may safely say that all were well cared for and showed the result of really good cultivation and of intelligent oversight, and even, although not in flower, were interesting from these facts.

There was yet another treat in store for me, the sight of a very choice collection of paintings of modern artists, comprising chef-d'œuvres of Landseer, David Cox, MacIise, Copley Fielding, Faed, and others, which Mr. Wrigley, sen., has collected in his fine house at Timberhurst close by—a collection which has been selected with the greatest care, and of which it is not too much to say that it is unsurpassed for high-class modern pictures of the English school.

Thus must end these few and very imperfect notes of a very pleasant visit, and in which, though a perfect stranger, I was received with that kindness and hospitality for which the north is so famous.—D., Deal.

ROYAL HORTICULTURAL SOCIETY.

MAY 21ST.

As a change from extensive displays that have been provided almost without intermission throughout the season a comparatively small number of plants only were exhibited at this meeting. Large exhibitions pending rendered it necessary for the great growers to make preparations for them; and as they have exhibited so splendidly at the oft-recurring meetings of the Society it is not surprising that both human and plant nature require a momentary rest. Yet several choice plants and some fruit were submitted to the Committees, which assembled in the Council room, and several certificates were awarded. Large groups of plants from Messrs. Rollisson & Sons and Mr. Wills, and a collection of cut blooms of *Irises*, &c., from Messrs. Barr & Sugden, were arranged in the conservatory.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Mr. Shirley Hibbert exhibited four pans of Erfurt Sweet Cress beautifully grown, to which a cultural commendation was awarded. The mode of culture adopted by Mr. Hibbert for this Cress will tend to introduce the Watercress as a permanent salad all the year round. Mr. Divers, gardener to W. Moore, Esq., Merton House, Maidstone, sent four dishes of Apples, to which a letter of thanks was awarded. Several pots of forced plants of *Vicomtesse Hericart de Thury* and *Garibaldi* were sent from the garden of the Society, and it was the opinion of the Committee that they were identical; also pots of *Marie Nicaise*, a large handsome fruit, but very acid. Mr. C. Howe, The Gardens, Benham Park, Newbury, sent three seedling Melons—Benham Hybrid Green-flesh, a cross between Scarlet Queen and Gilbert's Hero of Bath, a pleasant-flavoured fruit, but not in promising perfection; Benham White-flesh, a prettily-netted variety, raised from Orion crossed by Gilbert's Green-flesh, was not so good as the former; Benham Park Gem, also beautifully netted and scarlet flesh, raised between Scarlet Queen and Scarlet Gem. This is a very handsome fruit with a very juicy flesh for a red-fleshed Melon, and of excellent flavour. It was thought to be very much like Read's Scarlet-flesh, and not superior to that variety. It was proposed that the green-fleshed and the red-fleshed be seen again later in the season. Mr. Warde, The Gardens, Longford Castle, Wilts, sent a red-fleshed Melon called Longford Hybrid, which was of inferior merit.

FLORAL COMMITTEE.—Dr. Denny in the chair. Mr. B. S. Williams exhibited a small but choice collection of plants in the

Council room. *Sadleria cyatheoides*, a bold and stately Tree Fern from the Sandwich Islands, was awarded a first-class certificate. A similar award was made to *Alsophila plumosa*, a small Tree Fern with pinnae of great elegance. A similar honour was bestowed on *Adiantum neo-guineense*, a very free-growing Fern, having a general resemblance to *A. cuneatum* but a very much stronger and upright grower. It cannot fail to prove a valuable and popular plant for general decorative purposes. *Phycosperma rupicola*, a splendid Palm with broad, imposing, gracefully arched fronds, was also awarded a first-class certificate. It is a Palm of fine character, and will be valuable both for exhibition purposes and home embellishment. A similar award was made to *Cycas media*. Mr. Williams also exhibited the white-spathed *Anthurium A. Patinii* and *A. Dechardii*, the spathe of the last-named being very large and pure. A very elegant Fern in this group was *Nephrodium lucidum*, which is certainly one of the most chaste of this genus.

Messrs. James Veitch & Sons also exhibited a small collection of miscellaneous plants. *Hæmanthus Kalbreyeri* was awarded a first-class certificate. The flower stems are much marbled, and the flower heads are large and very rich. A botanical commendation was awarded for *Liparis elegantissima*, a dwarf terrestrial Orchid with foliage 4 inches long and 1½ broad, acutely ovate, green, with a broad creamy edge; the flower is inconspicuous but very singular. *Crinum Verschaffeltianum*, an introduction of Mr. Peter Veitch from the South Sea Islands, was exhibited. It is an imposing plant with broad arching foliage 3 feet long, green striped with white, after the manner of the variegated Maize. Very fine in this collection was *Tillandsia zebrina major*. Its large marbled leaves are extremely ornamental, but not more so than the brilliant scarlet flower spike, about 2 feet in length and resembling a fiery sword. Messrs. Veitch also exhibited a choice group of *Masdevallias*, including the extremely grotesque *M. chimera*, the brilliant yellow *M. Davisii* and some others; also the remarkable *Restrepia antennifera* and its variety *aurea*, which are both curious and beautiful. The same firm also exhibited the singularly elegant filmy Fern *Todea plumosa*.

Four very fine tuberous *Begonias* were exhibited by Messrs. John Laing & Co., and amongst them a remarkable double variety raised by M. Lemoine and named *President Burelle*. The flower has guard petals similar to a Hollyhock, and the centre is composed of numerous smooth and closely arranged smaller petals. The colour is rich scarlet, and the bloom resembles the flower of a Turban Ranunculus; the plant also is of dwarf sturdy habit. A first-class certificate was awarded. *Arago*, soft scarlet, and *Lælia*, vermilion scarlet, are fine single varieties; and *Carnicolor*, flesh-coloured, has very large flowers.

Mr. G. F. Wilson exhibited an admirably grown plant of *Lilium tenuifolium* with two stems and twenty-one brilliant and elegant flowers. It was very beautiful, and was awarded a first-class certificate. Mr. H. J. Buchan, Wilton House, Southampton, sent *Cymbidium tigrinum*, the plant being grown in a basket and bearing six flowers. A vote of thanks was awarded. A similar award was made to Mr. Douglas, who exhibited a plant of *Aquila cœrulea hybrida*, which is extremely beautiful, also cut flowers produced from seed saved from the new variety; these, though showing some slight variation, are still as attractive as the original. Mr. Cannell was awarded a vote of thanks for cut blooms of *Geraniums* of the true Swanley stamp—excellent; trusses of a new *Verbena*, *Esmeralda*, white, heavily striped and spotted with blue, were also sent by Mr. Cannell. Mr. Knight, florist, Battle, Sussex, exhibited his double striped *Vesuvius Geranium*; it is scarlet striped with white. It is a novelty, and will attract the attention of the floral curios.

The *Gloxinias* referred to on page 377 as being grown at Chiswick were submitted to the Committee, and to two of them—*Boule de Feu*, glowing crimson scarlet with white-mottled throat, large, and of good substance, and *Mont Blanc*, pure spotless white—first-class certificates were awarded. They were raised by M. Lemoine of Nancy. Double Ivy-leaved *Pelargoniums* raised by the same celebrated hybridist were also exhibited, to one of which, "No. 22," a first-class certificate was granted. The flower is large, round, double, and pale lilac in colour.

Mr. Wills arranged an extensive collection of plants in the conservatory. Prominent were three large pyramid *Azaleas*, one in the centre and one at each end of the group. Between them were *Palms*, and, beneath the *Palms*, *Spiræas* (*Hoteia*), very fine *Gloxinias*, and rich *Orchids*, the whole being edged with *Lysimachia nummularia* and *Isolepis gracilis*. Amongst the *Orchids* *Cattleya Mossiæ*, *Odontoglossum vexillarium*, *O. cirrhosum*, and *O. citreum* roseum were very beautiful.

Messrs. Rollisson & Sons, Tooting, also arranged a very large, varied, and excellent collection. Noteworthy amongst the flowering plants were the effective *Azalea Souvenir de Prince Albert*; *Sarracenia purpurea*, with twenty flowers; *Alyssum Wierbeckii*, one of the finest of all the *Alyssums*; *Saxifraga densa*, a charming plant; *S. granulata*, double white, distinct, and useful; *Viola pedata*, an attractive species and valuable for rockwork; and some ornamental-foliaged plants. Mr. Aldous, florist, Gloucester Road, Kensington, staged a bright and attractive group of orna-

mental-foliaged and flowering plants suitable for general decorative purposes. From the Society's Gardens at Chiswick came admirably cultivated plants of Harrison's Giant Musk, which is certainly one of the best decorative and window plants that have been recently introduced. Associated with the Musk were dwarf clearly striped plants of *Bambusa Fortunei variegata*, *Azaleas*, and *Panicum variegatum*. A collection of Cape *Pelargoniums* was also sent from Chiswick, some of which were curious, and several of them attractive. One of the best was a seedling raised by Col. Trevor Clarke from the good old Rollisson's Unique, and is a very pleasing colour, much paler than the parent. Mr. J. J. Wheble, Bulmershe Court, Reading, exhibited cut flowers of *Azalea pontica*, a brilliant group arranged in shallow pans, having been cut from a plant obtained from Messrs. Veitch & Sons fifty years ago. Its colour is orange scarlet, and is not surpassed by many modern varieties.

Plans of the grounds at Preston, where the great provincial Exhibition of the Society is to be held, and of the large exhibition tent, were exhibited in the Council room. They were closely examined by horticulturists, and did not meet with unqualified approval. The numerous and deep sinuities in the show tent were not only considered by many to be too narrow and formal, but fears were expressed that the ever-recurring nooks would impede the progress of visitors, and they will certainly cause the plants to be staged in them at a great disadvantage.

ROYAL BOTANIC SOCIETY'S SUMMER SHOW.

MAY 22ND.

THE first summer Show of this Society is usually not only extensive but highly attractive, the plants appearing to great advantage on the raised and well-arranged mounds in the large marquee. The Exhibition this year was neither quite so large nor so superior as usual. The *Azaleas* were generally smaller than they were last year, and some of them had lost their freshness. The *Roses* in pots, which are such a grand feature in a summer show, were much less numerous than on previous occasions, as also were *Pelargoniums*. Stove and greenhouse plants, Ferns, and *Calceolarias* were excellent, and imposing miscellaneous collections were exhibited; yet the Show, although not crowded, was an excellent one, and the collections were also excellently arranged.

Their Royal Highnesses the Crown Prince and Princess of Germany, family, and suite arrived at the Show shortly after twelve o'clock, and spent a considerable time in examining and admiring the several collections. The day was fine and visitors were numerous in the afternoon, and altogether the display was well worthy of their patronage.

STOVE AND GREENHOUSE PLANTS.—In the nurserymen's class for twelve plants in flower Messrs. Jackson & Sons, Kingston-on-Thames, won the chief place with comparative ease. The finest plant was *Epacris grandiflora rubra*, about 8 feet in diameter and splendidly bloomed; *Anthurium Scherzerianum* was very fine and extremely bright; *Aphelexis*, *Statice profusa*, *Ericas ampullacea*, *obovata*, and *affinis*, and *Clerodendron Balfourianum* were also very good, the plants averaging about 4 feet in diameter, and were well furnished. Mr. B. S. Williams secured the second prize with smaller plants, except in the case of two large *Azaleas*. A very fine specimen of *Dendrobium nobile* was exhibited in this group. Mr. Peed, Roupell Park Nursery, had the third prize. In the corresponding amateurs' class of ten plants collections of remarkable beauty were staged. The Judges, after close examination and long consideration, awarded equal first prizes to Mr. Tudgey, gardener to J. F. Greswolde Williams, Esq., Henwick Grange, Worcester; and Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley. *Azalea magnifica* in Mr. Tudgey's collection was quite 8 feet in diameter and closely bloomed; *Anthurium Scherzerianum* was magnificent; and extremely fine were *Aphelexis macrantha rosea*; *Ericas ventricosa*, *magnifica*, and *grandiflora*; *Clerodendron Balfourianum*, and *Statice profusa*. Mr. Chapman's plants were remarkably even in size, and were of undoubted high quality. They were composed of *Ericas Caven-dishiana*, *eximea superba*, and *odora rosea*; *Pimelea mirabilis*; *Azalea Mars*, very bright; *Dracophyllum gracile*, *Statice profusa*, an *Ixora*, *Epacris*, and *Bougainvillea*—a collection of great merit. An extra prize was awarded to Mr. Wheeler. For six plants in flower (amateurs), Mr. Chapman was awarded the first prize for very good specimens, the second honours going to Mr. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell; and third to Mr. Wheeler. In the corresponding nurserymen's class Messrs. Jackson & Son were in their usual place—first. *Epacris Eclipse* and *Erica coccinea superba* were the noteworthy plants in this group. Mr. B. S. Williams was second, the white *Azalea magnifica* in this group was really magnificent; and Mr. Peed was awarded the third prize.

ORCHIDS.—A moderate-sized but attractive bank of these aristocratic plants was arranged. In the amateurs' class for six plants Mr. Denning, gardener to Lord Lonsborough, was placed first with *Lælia purpurata*, *Odontoglossum vexillarium*, *cirrhosum*, and *luteo-purpureum*, *Dendrobium thyrsiflorum*, and *Cattleya superba*, all fine; Mr. Child was placed second (*Oncidium am-*

platum majus in this collection was very good); and Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., third. In the corresponding class for nurserymen Mr. B. S. Williams was first with *Cypripedium villosum*, *Maedevallia Harryana*, *Lælia purpurata*, *Odontoglossum Alexandre* and *O. vexillarium*, and *Dendrobium thyrsiflorum*. The second prize was awarded to Messrs. Jackson & Sons, Kingston.

ROSES.—This was the first meeting of the year of the renowned champions Messrs. Turner and Paul, who agreed in true chivalric spirit to have a fair and friendly contest in the class for nine plants, leaving the lesser class of six plants (an open one according to the schedule) at the disposal of amateurs. In the great class Mr. Turner won by many points. The plants were simply magnificent, some of them marvellous. Paul Perras was 7 feet high and 8 in diameter. *La France* was in grand condition both as regards foliage and blooms. Charles Lawson and Madame de St. Joseph were splendid. Duke of Edinburgh, though smaller, was very full and glowing. Mlle. T. Levet, Maréchal Vaillant, Céline Forestier, and Juno completed the collection. Messrs. Paul and Son, the Old Nurseries, Cheshunt, who were second, undoubtedly exhibited some grand plants, notably Madame Victor Verdier, Madame de St. Joseph, and Céline Forestier. Dr. Andry had also very fine blooms; but the remainder—Marie Baumann, Madame Thérèse Levet, Miss Ingram, Paul Verdier, Victor Verdier, and Anna Alexieff, were somewhat deficient in foliage, or at least it was not so exuberant as that of the Slough plants. In the "open" class for six plants Mr. Moorman was the only exhibitor, but his plants had passed their best, and they were awarded the second prize. In the class for twenty Roses, not less than ten varieties, in 8-inch pots (nurserymen), Mr. Turner was again in the foremost place with handsome specimens. *Perfection de Montplaisir*, Madame Victor Verdier, Royal Standard, Beauty of Waltham, and Madame Lacharme were in admirable condition. Messrs. Paul & Son were second with smaller but very good plants and fine blooms. The same firm were the only exhibitors in the class for six new Roses sent out in 1876-77, and were worthily awarded the first prize. The varieties were *Magna Charta*, very fine; Madame Sophie Tropic, Duchesse de Vallombrosa, Marquise de Murinais, Duke of Connaught, Emily Laxton, and Madame de Mouchaveau, a fine Rose in excellent condition.

AZALEAS.—A few large specimens were exhibited, but generally the plants were smaller than usual. In the amateurs' class for six plants Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham Hill, was placed first for moderate-sized and well-bloomed specimens. Mr. Child was second, and Mr. Wheeler third. In the corresponding nurserymen's class Mr. C. Turner, Slough, was first with very fine informally trained specimens, in which good foliage is visible as well as fine flowers. *Souvenir de Prince Albert* was extremely fine in this collection. Messrs. Jackson & Sons were second with moderate-sized specimens. The next, an open class, was for twelve plants in 12-inch pots, six varieties. Mr. Ratty had the first place with medium-sized specimens remarkably well bloomed. The same exhibitor was first in the amateurs' class of six plants.

HEATHS.—The plants were generally small and, with a few exceptions, were not of superior merit. In the nurserymen's class for twelve plants in 12-inch pots Messrs. Jackson & Sons were placed first and Mr. Peed second. In the amateurs' class for six plants Mr. Tudgey was placed first. Very handsome were *E. tricolor Wilsoni* and *E. ventricosa coccinea minor*. *E. v. magnifica* was very large. *Tricolor speciosa*, *tricolor elegans*, and *Cavendishiana* completed the group. Mr. James Weston, gardener to D. Martineau, Esq., Clapham Park, had the third prize for small healthy plants.

PELARGONIUMS.—These always make a fine display at an early summer show. Plants of the show varieties are not grown so large as formerly, but they are none the less effective on that account, for we generally find the finest flowers and best varieties when medium-sized plants are exhibited. In the open class for nine plants in 8-inch pots Mr. James, gardener to W. F. Watson, Esq., Redlees, Isleworth, was first with very large specimens—one plant, *Prince Leopold*, was about 5 feet in diameter and very brilliant. In the amateurs' class for six plants in 8-inch pots Mr. James was again first for well grown and symmetrically trained plants; Mr. Hammond, York Lodge, Stamford Hill, was placed second, and Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, third. In the corresponding class for nurserymen Mr. Turner was in the premier place with plants 2 to 3 feet in diameter. The varieties were *Archduchess*, *Troubadour*, *Isabella*, *Claribel*, *Jane*, and *Pompey*. Both plants and flowers were excellent. Mr. James was awarded an extra prize for a collection of splendidly grown fancy Pelargoniums.

CALCEOLARIAS.—The rich masses of these plants when well grown are surpassed by no others of moderately dwarf growth. We have seldom seen them better than on this occasion. In the open class for nine plants Mr. James was in his old place—first, with dwarf grandly grown specimens with heads 2 to 3 feet in diameter. The champion had, however, a formidable competitor in Mr. Rapley, gardener to R. Hudson, Esq., Clapham Common, who had the second prize with plants rather smaller than Mr.

James's, but with larger flowers and in greater variety of colour. Extra third prizes were awarded to Mr. Coppin, nurseryman, Croydon, and Mr. Ford, Windermere House, Upper Norwood.

GLOXINIAS.—These beautiful decorative plants were represented by two well-grown collections. In the open class for twelve plants Mr. C. Hammond, gardener to F. K. Hunt, Esq., York Lodge, Stamford Hill, was placed first; and Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, second. The second-prize plants were the finest—the first the best varieties.

EXOTIC FERNS.—These graceful plants are always admirably exhibited at "the Park," and on this occasion they were truly excellent. In the amateurs' class for six plants Mr. Tudgey won the first honours with grand examples of *Cibotium regale*, *Cyathea medullaris*, and good plants of *Adiantum tenerum*, *Davallia Mooreana*, and *Gleichenia rupestris* and *Mendeli*. Mr. Wheeler was placed second for smaller but healthy plants. In the corresponding nurserymen's class Mr. B. S. Williams, the only exhibitor, was placed first with an extraordinarily fine collection composed of *Cyathea Burkei*, *Dicksonia antarctica*, *Asplenium nidus-avis*, two grand *Gleichenias*, and *Davallia Mooreana*.

FINE-FOLIAGED PLANTS.—These, like the Ferns, were also excellently represented. In the amateurs' class for six plants Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, were first with a grand collection consisting of *Verschaffeltia splendida*, *Areca aspidia*, *Latania borbonica*, *Crotons variegatus* and *pictus*, and *Dasyllion glaucum*, all very large and in admirable condition. Mr. Tudgey was placed second, and Mr. Ford, gardener to J. G. Megaw, Esq., Windermere House, third. An extra prize was awarded to Mr. Fisher, gardener to F. Williams, Esq., Nightingale Lane, Balham. In the corresponding class for nurserymen Mr. Williams was awarded the premier prize for a superior collection.

In the open class for a group of twelve plants of *Agaves*, *Yuccas*, and *Cycads*, Mr. Rann, the only exhibitor, was awarded the first prize. *Cycas circinalis* and *C. revoluta* were large and in splendid condition, the *Agaves* were small. In the class for twelve Alpine plants in pots Mr. R. Parker was awarded the chief prize.

The 'miscellaneous exhibits, which were extensive and highly meritorious, contributed greatly to the success of the Exhibition. Extra prizes were awarded to Messrs. Veitch & Sons for a magnificent group of *Rhododendrons* and Japanese Maples; to Mr. B. S. Williams for a large and rich collection of new and fine ornamental-foliaged and flowering plants; Messrs. Lane & Son for a fine group of *Azaleas* and cut blooms of *Rhododendrons*; Messrs. Rolleston & Sons for a choice collection of ornamental-foliaged and Alpine plants; Messrs. Osborn & Sons for a remarkably healthy collection of *Palms*; Messrs. Cutbush & Sons for *Rhododendrons*; Messrs. John Laing & Co. for a rich and varied group of stove and greenhouse plants; and Mr. Heims for a capital collection of *Orchids*. Mr. Ware, Tottenham, exhibited the useful forcing *Pink Derby Day* and other flowers; and Mr. Rapley extremely dwarf *Cockscombs*. They were extremely fine considering the earliness of the season.

Certificates were awarded to Mr. B. S. Williams for *Dendrobium superbiens*, *Crotons Prince of Wales* and *Queen Victoria*, *Draecenas Scottiae*, *Berkleyi*, and *Fredericki*; *Calyptronoma Swartzii*, *Dendrobium bigibbum superbum*, *Ptychospermum rupicola*, *Asclepiha plumosa*, *Sadleria cyatheoides*, and *Anthurium Dechardii*; also to Messrs. Veitch for *Amaryllis media*, *Adiantum cyclosum*, *Coleus George Bunyard*, *Crinum Verschaffeltianum*, *Platyterium Hillii*, *Areca gracilis*, *Ptychospermum rupicola*, and for *Rhododendrons Crown Prince* and *Crown Princess of Germany*.

NOTES AND GLEANINGS.

THE great SUMMER SHOW OF THE ROYAL HORTICULTURAL SOCIETY, which opens at South Kensington on the 28th inst. and continues for four days, is expected to be a very large and imposing one. The prizes offered are very liberal. In the open class for twelve stove and greenhouse plants the amounts offered are £20, £15, and £10. In the nurserymen's and amateurs' classes for eight plants the prizes are respectively £10, £7, and £5. *Orchids* are generously provided for, the prizes in the amateurs' class for fifteen plants being £20, £15, and £10: amateurs have also a class for ten plants with prizes of £12, £8, and £5. Nurserymen are offered £15, £10, and £7 for fifteen plants, and £6, £4, and £2 for six plants. Sir Trevor Lawrence, Bart., M.P., also provides a prize of £10 for the best specimen *Orchid* not made up—that is, not a group of several plants in one pot. The prizes for *Azaleas*, *Ericas*, *Palms*, *Roses*, &c., are such as may be expected to bring out the best plants in the country, and prizes of £10, £7, and £5 are provided for a group of miscellaneous plants arranged for effect in a space not exceeding 300 square feet. Amongst the special prizes we observe that Mr. Bull offers twelve silver cups for plants of his introduction, and Mr. F. Gallop, Brighton, provides prizes of £10, £7, and £5 for twelve plants of Miles's

Hybrid "Spiral" Mignonette to be grown in 6-inch pots. Good prizes are also provided by the Society for fruit and vegetables. The charges for admission to the Show are such as ought to insure a large attendance of visitors. The first day, Tuesday, is a 5s. day, or 3s. 6d. if the tickets are purchased previously; Wednesday and Thursday are 1s. days; and on Friday the industrial masses can obtain admission for the low charge of 6d. each.

— At the READING HORTICULTURAL SOCIETY'S SHOW, which is announced to be held on the 23rd inst., we are informed that, besides the liberal prizes provided by the Society, a Veitch memorial medal and a prize of £5 will be offered for three stove and greenhouse plants, Orchids excluded.

— A MEETING of the promoters of an INTERNATIONAL HORTICULTURAL EXHIBITION was held at South Kensington on Tuesday last to consider the desirability of holding such an exhibition in London in 1879. G. T. Clark, Esq., occupied the chair. There was a good attendance of the leading horticulturists, among whom were Messrs. Veitch, Williams, Bull, W. Paul, George Paul, Baines, Wills, Dean, Kellock, Moore, Rollisson, Dr. Denny, Dr. Hogg, and others. It having been decided at a preliminary meeting that an International Exhibition shall be held in London in 1879, that decision was confirmed, and a Committee was appointed to carry out the arrangements, and Mr. Thomas Moore was chosen Secretary.

— AMONGST the trials of plants at Chiswick this year not the least interesting is the collection of CAPE PELARGONIUMS. The Society has obtained upwards of sixty species and varieties, many of which are extremely pretty. One of the most distinct is *P. hypoleuse*. The flower is perfectly round, and resembles in form the small wild *Convulvulus*. The colour is pale lilac, with distinct dark purple radiating veins and a white disk. It is very attractive, and is suitable as a decorative plant for the front row of a greenhouse stage.

— ONE of the most noticeable features in Messrs. Osborn and Son's nurseries at Fulham just now is the collection of HARDY AZALEAS. Many of the shrubs are 8 or 9 feet in height and from 7 to 9 feet through, and some even more, and the effect of their great and varied mass of colour is very imposing. Amongst the most noticeable varieties are *A. pontica macrantha*, bright yellow, perhaps the largest flower of the group; *Atro-rubens*, deep orange; *Aurantia*, reddish orange; *Elegantissima*, reddish orange, upper petals bright orange; *Coccinea* major, very fine and effective; *Lutea rubicunda*; *Magnifica*, cream colour, good truss, and flower quite distinct; *Speciosa*, very free and attractive; *Grandinosa*, reddish crimson, very rich; *Gloriosa*, a charming variety; *Electa*, a dense-habited variety, and very pretty; *Incarnata*, a fine flesh-coloured variety; *Viscosifera*, very pale yellow, but telling; and *Ne Plus Ultra*, very fine. These are only a few of many that are contained in this remarkable group; there are many not open yet, so that the collection will be attractive for some days to come.

— Few things impress visitors to our nurseries more than observing the immense numbers of plants or trees of particular kinds that are provided to meet the public demand, and it becomes a matter of wonder to them, as indeed it well may, as to where the surprising numbers of Vines, Roses, and Orchids go. One of the most extraordinary IMPORTATIONS OF ORCHIDS that have ever arrived in this country has been received recently by Mr. Bull at Chelsea. We are informed a small selection of ten thousand plants was sold at Stevens's rooms the other day, but the abstraction of even that considerable number was scarcely perceptible. If supply creates demand, as it does in the case of so many commodities, Orchid culture should receive a great impetus by the arrival of such an enormous importation as the one alluded to. Amongst the established Orchids some beautiful varieties of *Odontoglossum vexillarium* are flowering, and *O. Pescatorei* and *O. crispum* have spikes of great massiveness. Next to the Orchids the Lilliums and small plants of the Liberian Coffee arrest attention by the remarkable numbers in which they are represented.

— THE crops of CABBAGES in THE LONDON MARKET GARDENS are this year unusually extensive, early, and fine. For some weeks past enormous quantities have been transmitted to the various markets at prices considerably lower than the growers are in the habit of receiving, yet when the Cabbages are retailed in the markets there is no material reduction in prices to consumers. It is commonly supposed that the products of the vegetable fields near London are wholly disposed of in the metropolitan market; but this is not so. On

the contrary, hundreds of tons of vegetables are sent by train to the large towns in the north—Liverpool, Manchester, Leeds, Bradford, &c. Indeed, of the Cabbage crop which is now being cleared it is probable that quite half of the bulk is sent to the north, if we may judge by the railway vans that are in the fields every morning as soon as it is light. In this way hundreds of piled-up loads, representing many tons of Cabbages, are sent away, and in the course of a week the greater portion of the Cabbage crop will be cleared off the land.

— WE have seldom seen such a profuse display of BLOSSOM ON THE HOLLIES as during the present year. Although the shrubs generally produced unusually large crops of berries during the winter they have lately been thickly clustered with white flowers. On some of the splendid specimens in Victoria Park we observed last week large clusters of scarlet fruit still adhering to the branches, and between the fruit the blossom was forcing its way and expanding. Other specimens, from which the berries had fallen, were just setting their fruit, and the ground in some places was quite white with fallen petals. This circumstance, and the fine weather prevailing, are good indications that Holly berries will again be plentiful for Christmas decorations.

— OWING to the extremely mild and genial weather that has lately prevailed BROCCOLIS have come in "all at once," and there has recently been a "glut" of them in the London market. Almost every greengrocer's shop and costermonger's barrow contains huge piles of white close heads which have to be cut and sold at such prices as they will realise, for if left on the ground the heads speedily expand and are worthless. Splendid heads are gladly sold retail at 1d. each and even less; and when it is considered that the middlemen usually secure the lion's share of the profits on vegetables, Broccolis this year can scarcely be remunerative to the cultivators. The public, however, having a share in the advantages incident to the season, and since the great bulk of consumers have usually to pay so dearly for fresh and wholesome vegetable food, we cannot begrudge them the facilities they are at present enjoying in the supply of Broccolis.

— EXCELLENT as the GRAPES have been at Loxford Hall during past years the crop this year is as promising as ever. When we saw the Vines a short time ago we were much impressed with the great cleanliness and healthy hue of the foliage, the thinly trained laterals, and the regular crops of fruit in the different houses. It is evident that the syringe is very little employed, if at all; but insects are kept at bay by promoting stout foliage and by the fumes of ammonia from fermenting material placed in the houses. Buckland Sweetwater and Black Hamburgs are bearing excellent crops, and there is an admirable set of Canon Hall Muscat. The advantage of training up young rods is very apparent, for it is on those that the best Grapes are produced. Mrs. Pince, however, is showing splendidly on the same spurs which have produced fine fruit for nine or ten years. Duke of Buccleuch is carrying two or three bunches containing fine berries, but there are manifest signs of rust, from which other varieties in the same house are quite free. Muscat of Alexandria growing in a narrow border about 3 feet wide and 4 or 5 long quite fills a moderate-sized house, the Vine being grown on the extension system, and the rods trained down the rafters from the back to the front. The crop is a very fine one, and the berries have set with great freedom. Although a genial atmospheric moisture is provided in the houses there is no semblance of steaming and no air-roots on the Vines.

— WE warn our readers not to betray the place where any RARE PLANT is to be found. The habitat of one of the scarcest of the Veronicas was told by us, and the plant has been extirpated by insatiate botanists. Sir Henry Holland records a similar experience. He says, "I made myself a frequent guide to those who came to obtain specimens of the *Saxifraga Hirculus*, growing on a small detached spot in a marsh close to Knutsford, the most southern English locality, as I believe, in which this plant has been found. Years after, when I came to look for it on the well-known place, it had wholly disappeared."

— THERE were many PLANTS in BLOOM in the open air at Eastertide in Glamorganshire which do not flower so early outdoors in all parts of the country. Lily of the Valley, Narcissuses, Tulips, Forget-me-nots, Anemones, &c., were then blooming. Against the church wall at Margam a plant of *Clianthus carneus* was a fortnight ago bearing many drooping clusters of its curious-shaped pale red flowers. Close to it Climbing Devoni-

ensis Rose is flowering freely. Gloire de Dijon is still more advanced, and the miniature, perfectly rose-shaped, lemon-coloured, double cherry-like blossoms of the lovely little Banksian Rose are coming out in profusion. A red Camellia covering about 5 square feet on the wall has over one hundred blooms fully open at the present time. One Double White Camellia bush growing amongst other shrubs has many hundreds of flowers expanded now, and many are over, but the later they are in blooming the better, as the blooms do not remain long perfect early in spring.

— A NEW CIGARETTE PAPER.—It is stated, says the "British Trade Journal," that a Spanish firm of papermakers are producing a kind of cigarette paper made from Watercress. It is said to be much less irritating in smoking than the ordinary description, and to have a beneficial effect upon the lungs in pulmonary disease.

MELBOURNE BOTANIC GARDENS, VICTORIA.

WE have received Mr. Guilfoyle's (the Garden Curator) report of these gardens, and are very pleased to read the details, for they are all satisfactory, except those relative to the Rose. Some of our readers might aid the Curator by sending cuttings.

Mr. Guilfoyle says—"The Fern Gully in the Botanic Gardens is now one of the great attractions in the grounds, and it has quite fulfilled the expectations I expressed concerning it in my first report. The large Ferns have flourished, and now spread their cool green fronds over the small species growing beneath their shade. The aspect of the place is quite a natural one, as it should be; and while the shelter trees transplanted there afford the requisite shade, it has been freely planted with Stag's-horn and Elk's-horn Ferns, which give increased beauty and appropriateness to the spot. A number of tall Tree Ferns from Mount Macedon have been planted here, and are growing vigorously. I am indebted to Walter Hill, Esq., Director of the Brisbane Botanic Gardens, and Lewis A. Bernays, Esq., F.L.S., of the Brisbane Acclimatisation Society, for some valuable Ferns which were very scarcely represented in the Melbourne Gardens. From these gentlemen I received specimens of the Platyceriums and Bird's-nest Asplenium, &c., with which the stems of the Tree Ferns—*Alsophyllas*, *Cyatheas*, and *Dicksonias*—and many of the shade trees were clothed, forming capitals to the columns of the trunks and relieving the dull hue of the stems with their pale green. Scores of large trees redundant and useless in other portions of the grounds were transplanted to this Fern Gully (over two hundred specimens) for the protection of the Ferns. Climbers have also been extensively planted. Banksian and Cloth of Gold Roses, *Loniceras*, *Ipomæas*, *Bignonias*, *Solanum jasminoides*, *Mandevilla*, climbing *Pelargoniums*, &c., were placed at the stems of the trees, and these will ere long, supplemented by the umbrageous trees, afford a canopy of shade. Amongst the trees are fine specimens of *Alnus*, *Grevillea robusta*, *Dammara robusta*, *Robinia*, *Buddleia*, *Brachychiton populneum*, *Brachychiton acerifolium*, all of which are thriving. A tall Tree Fern 40 feet high and quite a novelty has been planted here. It is, I believe, an undescribed species, but is probably a *Cyathea*. This fine specimen was obtained in the Cape Otway Forest a month or two ago and transplanted to the gardens. If it lives it will be a great acquisition to the Fern Gully. The bridge which formerly crossed the Gully, and which was not only unsightly but in a state of decay and dangerous to visitors, has been removed. In my last annual report I mentioned the removal of the aviaries from this spot and the filling-up of a waterhole near them. The whole of this part is now included in the Fern Gully. Many of the trees formerly growing in the spaces now occupied by the new lawns were removed to this Gully. The walk replacing the bridge now dips into the hollow, affording a good view of the Fern Gully, with a background at the lower end of the islands in the lake. The overflow from the new reservoir may be here used most effectively in the creation of a trickling stream winding over the rocky boulder-strewn bed of the Gully. The sight and sound of such a stream would be in harmony with the surroundings, and add to the natural appearance of the spot. A rockery has been made on the Buffalo-grass lawn near the Gully. The Ferns both large and small have developed luxuriant fronds, and in summer time the cool sequestered shade of the spot is generally appreciated. It was suggested when the Gully was in process of formation that the Ferns would fail before the trees planted could afford the top shade, but I am happy to

say these prognostications have proved worthless, the matter being successfully accomplished during the second season for transplanting since my appointment. The Fern Gullies of Victoria should be imitated in these Gardens as opportunity allows. In these, more than anything else, the highest order of beauty is in the natural aspect given. Many cartloads of stones have been brought from the grounds of the Kew Asylum for making rockeries, &c., in the Botanical Gardens."

PLATYCERIUMS.

In this genus we have a few plants of great beauty and entirely unique appearance, as they differ totally in habit from all other known Ferns. In the general arrangement of Ferns we find them associated with *Acrostichums*, from which, however, they are very distinct; indeed the veteran pteridologist J. Smith, in his "*Historia Filicum*" lately published, elevates them into a distinct tribe (*Platycerieæ*), of which this genus is at present the only representative. This view has not found much favour amongst those who make Ferns their study from dried specimens only, but those having paid much attention to these plants in a living state will feel convinced of the correctness of this author's views. These remarks, however, will perhaps have little interest to the amateur horticulturist, and we shall therefore at once come to the adaptability of *Platyceriums* as ornaments to the fernery.

In the first place *Platyceriums* are epiphytall Ferns, growing naturally on the branches and in the forks of the forest trees, sometimes low down, at others high up amongst the topmost branches, which the barren shields or fronds seem to clasp for support, whilst the long, forked, fertile fronds are produced at right angles with them. To grow these plants successfully they must be suspended in baskets or placed upon a broad block of wood after the manner of an Orchid, when if kept moist the spongy roots will soon adhere to the wood, and the plant commence to put forth its beautiful fronds, which from their peculiar ramifications have led to their popular name of "Stag's-horn Ferns." Another system is pot culture; but to say the least of this it is attended with more trouble, and it does not allow the plants to display their beauties in the best manner. Pot culture is adopted in the fernery at Kew for these plants, but in this case the pots are made with a low side, so that the plants stand in the same position as when grown upon blocks. Even this system we should not advocate, for our experience with these particular pots and plants has fully confirmed us in the block or basket system. It will now be seen by our readers that the culture of *Platyceriums* or Stag's-horn Ferns is very simple; indeed nothing is required but a little sphagnum moss about the roots, and a due supply of heat and moisture. The blocks for these plants should be broad, because the barren fronds are thus compelled to spread over instead of clasping round it, and the beauty is enhanced. We have heard blocks condemned on account of their liability to decay; but this is no real obstacle, as we have known plants of *P. grande* to occupy the same piece of wood for fifteen years.

Platyceriums are mostly stove Ferns. It is true that *P. alci-corne* and its varieties thrive in the greenhouse, but always make finer specimens when treated to stove heat. Scale and thrips will attack these as well as most other plants. In the case of the former careful hand-picking is the only remedy. The latter is generally brought about by too much heat and too little moisture in the atmosphere, the remedy therefore is obvious. The following are all the species in cultivation; all are distinct, and all deserve a place in the fernery of the amateur.

P. alci-corne.—The barren fronds of this plant are nearly round, closely overlapping each other, sessile, clothed with stellate hairs; colour light green. The fertile fronds stand almost at right angles, narrow at the base, becoming broader as they ascend, and forked at the apex; dark green above, clothed below with stellate hairs, the patches of dark brown sori occupying the lobes. It will thrive either in the greenhouse or stove, but, as before remarked, attains finer proportions in the latter. Native of the Malay Archipelago and Australia.

P. alci-corne majus.—A remarkable and handsome form of the species. The sterile fronds are very large and sub-erect, and the fertile fronds are also broader with more divided margin. It is a distinct and very ornamental variety. Native of Australia.

P. biforme.—A rare and little-understood species amongst cultivators, as we have frequently seen *P. Stemmaria* grown for it, from which, however, the true plant is very distinct. Sterile fronds broad and overlapping each other, deeply forked

on the upper edge. Fertile ones long, pendulous, and much branched; the segments narrow strap-shaped, whilst the portion of the frond which bears the sori is reniform. Native of Borneo, Moulmein.

P. grande.—This is a truly noble species, the barren fronds

spreading out several feet if placed upon a suitable block. They are broad and imbricating, deeply forked on the upper edge but smooth below. The fertile fronds grow out from the base of the barren at right angles, attaining a length of some 3 feet (in strong specimens), becoming pendulous. Whole

Fig. 59.—*PLATYCERIUM HILLII*, F.M.

plant apple green, clothed with a pubescence of stellate hairs, which give it somewhat a hoary appearance. Native of the Malay Archipelago and Australia.

P. Hillii.—We have some doubts as to this plant being distinct from the one distributed by the Messrs. Veitch & Sons under the name of *P. alcornae majus*. It is apparently a very handsome form, and seems to differ from the last-named variety in the greater breadth of the apex of the frond and in the more numerous and deeper ramifications, as will be seen

from our illustration (fig. 59), which is taken from a photograph received from Queensland, and for which we are indebted to the kindness of Mr. Hill, Curator of the Botanic Garden, Brisbane, after whom it has been named by Baron F. Mueller.

P. Stemmaria.—This species is also known by the name of *P. æthiopicum*. It is at once distinct from all the other species, and differs from them inasmuch as the sterile fronds only live one season, at the end of which time they turn brown and remain on the plant for many years, the young ones soon

covering them on the return of spring. They are large, sessile, sub-ascending, 1 to 2 feet in diameter, and bright green. Fertile fronds 1 to 2 feet long, broad, and coriaceous in texture. dichotomously forked at the apex. The sori occupy the apex of each lobe on the under side. Whole frond clothed with a dense, hoary, stellate pubescence. The roots are viviparous and at intervals produce young plants, so that this species will if undisturbed soon make an immense specimen. Native of West Africa.

P. Willinkii.—A species of very recent introduction, which has not yet shown its true character under cultivation; it is, however, an extremely beautiful plant, and is sure to be in great demand when better known. Sterile fronds sessile, erect, imbricating, dichotomously forked all round the edge, and upwards of a foot in height. Fertile fronds produced from the sinuses of the sterile ones, usually three together, 2 to 3 feet long, pendulous, narrow, and much divided into long narrow segments, bearing the sori near the tips on the under side. Native of Java.

ONIONS FOR PICKLING.

In highly enriched private gardens about one of the most difficult crops to supply to the cook's satisfaction is the crop of pickling Onions; yet the London market gardeners manage to produce a supply of "picklers," although their ground is at least as highly manured as that in the best cultivated private gardens. It is well known that if the subsoil of even the richest ground is brought to the surface in any large quantity, that, to use an expressive and familiar phrase, "nothing will grow in it." That, however, is exactly correct, for the keen and observant market gardeners have found that that is precisely the kind of soil for producing small, round, marble-like Onions. To produce a supply of suitable bulbs they simply trench a portion of ground somewhat deeper than before, bringing up 5 or 6 inches of sour subsoil to the surface, and in this they sow the seed very thickly at the present time. The plants are not thinned, and by the time they are 6 inches high they have exhausted the soil so much that the blade turns yellow and the bulbs mature, and about July they are pulled up and spread on the ground to prepare for market. Nothing at that period of the year arrests the attention of the visitor to the market grounds more than the enormous quantities of matured Onions about the size of hazel nuts that are provided for pickling for the million. The crop is in itself a remunerative one, and it is obvious to practical gardeners one turn-over of the ground lately occupied by the "picklers" renders it admirably suited for any crop that may afterwards be grown in it. This practical hint can scarcely fail being useful to many gardeners at this time for carrying it out and producing with certainty a full supply of pickling Onions.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 21.

THE great group of the Geometrine Moths, which contains nearly or about three hundred species, is one of the best defined of the groups in the order Lepidoptera, and though we have (as seems to be the case in almost every natural division) a few species that present notable peculiarities, a strong family likeness runs through the whole. It is only necessary to name such well-known insects as the Gooseberry Moth, sometimes misnamed "Currant," and the Winter Moth, to present at once an illustration of what a Geometer is; but it is not to be supposed that the majority of the species are as injurious in our gardens as are these two. The group contains some very rare species, and a good many never found at gardens or plantations, while even of those that frequent cultivated ground a proportion are not plentiful enough to do harm. Yet there are within the group sundry species beside the above-cited which the horticulturist would like to find "conspicuous by their absence." It is a group even more recognisable in the caterpillar than in the moth condition, for the caterpillars, lacking six of the pro-legs or claspers with which their brethren in the other groups of moths are endowed, adopt a singular mode of progression, which originated the name of Geometers—i.e., "Ground Measurers," applied to them. They have also been termed Loopers, because in walking they bend or loop the central part of the back. Suppose a Geometer caterpillar at rest (the position of rest, by the way, often implies with them a swinging of the anterior part of the body in the air in a manner that appears to us far from comfortable) and then

resolving to begin a perambulation: tightening the hindmost claspers on the leaf or branch the caterpillar stretches out its head towards the point that offers some attraction, and grasps the substance with the fore legs as far off as it can. The body is thus straightened, and the next motion is to bring up the hind legs close to the fore legs, the middle of the body then bending into the loop. Again the head is advanced, the same process repeated, which, though it cannot be rapidly described, carries the caterpillar on at a good speed; indeed, in the case of some species much of the life of the caterpillar is spent in seemingly purposeless wandering over the food plant. Therefore it follows that if a Looper caterpillar is started, say, on a walking-stick 3 feet in length, the number of strides taken in passing along it can easily be counted. The moths of this group have mostly thin bodies, and the wings are broad. Their favourite attitude on walls or tree trunks is to sit with them extended. The hind wings are seldom tucked under, as is so commonly done by fat-bodied species. The fore and hind wings often resemble each other, the pattern or design being sometimes continued over all the wings, as in several of the "Thorns," that are of frequent occurrence in parks and shrubberies. Sober tints of colour also prevail.

The long muster roll of Geometers is headed by that singular insect the Swallow-tailed Moth (*Uropteryx sambucata*), our sole British representative of a large family, and which flits languidly about the hedges in the summer, having occasionally from country folks the name of "moth owl," given indiscriminately to a number of nightfliers of pale or dull hue and slow flight. Its caterpillar when nearly adult has often been mistaken for a twig. In food it has some eccentricity, for though it usually feeds on the Elder or some fruit tree, it now and then condescends to the humble *Myosotis*. The family of the Thorns contains some species with stoutish bodies, such as, for example, the August Thorn (*Ennomos angularia*), common even in London parks, the caterpillar feeding on Elm and Oak. Probably the handsomest Thorn is the Lilac Beauty (*Pericallia syringaria*), but it is not abundant enough to injure the Lilac or any other shrub the caterpillar may select for food. The only species in the family that lies under suspicion is the Brimstone Moth (*Rumia crataegata*), yet this generally limits itself to the Whitethorn. In the next family, the *Amphidasydæ*, we have stout-bodied moths. One out of the six is the Brindled Beauty (*Biston hirtaria*); not beautiful to gardeners when the caterpillars swarm on Pear or Plum trees, as they do in some seasons. Amongst the Boarmidæ we have a considerable variety. One pretty species rather common is the Waved Umber (*Hemerophila abruptaria*), seen on our palings in April or May; the caterpillar eats the leaves of the Lilac or Rose. *B. perfumaria*, misnamed the Willow Beauty, since it has no special elegance, nor does it resort to the Willow, when a caterpillar attacks the uninviting foliage of the Ivy; and the freckled caterpillar of *Cleora lichenaria* manages to live on the little lichens on palings, as do two others in that genus. In June we find about gardens the pretty *B. repandata*, deserving to be called Mottled Beauty, and which, charmed by its delicate markings in grey, orange, and brown, the gardener may well refrain from crushing when he sees it on a wall, for the caterpillar does little damage to the Plum or Birch, its wonted food.

The Emerald Moths present a curious group of varying size, all of a greenish tint but not injurious. The Little Emerald (*Iodis lactearia*), swarms in many copses. Of one species, *I. vernaria*, it may be said in the feminine phrase, that its wings are of a "most lovely green." Personally, I always associate that species with Ham Common, for I first captured specimens there, and as it happened caught nothing else at the spot, which is perhaps discommenced now like other open places near London. In the *Acidalidæ* we have a group of small species of some delicacy of appearance, many species from their markings having the name of "Wave" applied to them. The Small Dusty Wave, a little moth which might be covered with a shilling, is common in shrubberies. Several of these have their wings more or less "scalloped." The small group *Macaridæ*, containing a few scarce species, brings us also to the Moth (*Halia wavararia*), the caterpillar of which is a Gooseberry pest in some years; it will feed also, as I have observed, on other plants in the kitchen garden. Individuals of the same brood will be found of such different colours that we might be led to think they were not of one species. Like many other troublesome caterpillars, it is best dealt with by careful hand-picking. *Panagra petrararia*, also called the "Brown Silver-line," is notable in another group of smallish

species, because the caterpillar feeds on Ferns, preferring the common Brake. It will be within the observation of every gardener that the various species of Ferns are seldom attacked by caterpillars, though they have their share of other insect enemies. Amongst the Fidonidae, *F. atomaria* is a common and pretty species, very partial to heaths and commons, where the caterpillars subsist on the species of Trefoil.

A small family of five species contains that important species the Gooseberry Moth (*Abraxas grossulariata*), and the nearly allied *A. ulmata*. Much has been written on the history of this insect, so annoying in its attacks upon Gooseberry bushes, and less frequently upon the species of Currant. It would probably be far more abundant were it not that the hibernation of the caterpillars exposes some portion of each brood to the chance of dying in winter, either from the weather or through the researches of hungry birds. Cold, however, they manage to endure pretty well, for a naturalist has reported that he found a number of them so congealed as to chink like little pebbles when they were thrown into a garden pot, but afterwards they revived. They will not always remain on the bushes through the dull season; many hide in nooks, where they escape birds and also gardeners. It is a peculiarity in *A. grossulariata* that it occurs along hedges and in woods as well as in gardens, and I have a keen recollection of collecting several of these caterpillars from a pollard Oak. And the fact that they feed on the Hawthorn occasionally, suggests that they might attack allied plants under culture. *A. ulmata*, the Clouded Magpie, is a handsomer but less common species, with a gaily-coloured caterpillar that feeds upon the Elm.

The family of the Hybernidae contains only a few species, but the caterpillars are very destructive in several instances, and we have in this family the curious circumstance that the females are wingless; notwithstanding this they are very prolific. One species, the Winter Moth (*Cheimatobia brumata*), often requires all the efforts of the gardener to keep it down; the injury done by it is increased by its eagerness in attacking buds and its skill in concealing itself amongst the foliage. The Mottled Umber (*Hybernia defoliaria*) is another species which frequently displays its thousands of caterpillars, but these confine themselves usually to the woodlands. In the "large small family" of the Pugs—to use an Irishman's phrase—we have some species that occur in gardens, the larvæ having a penchant for the flowers of plants, yet they are hardly to be called pests, but simply annoyances. There is something in the form of the moths (*Eupithecia*) so peculiar that when one has once been recognised it can hardly be forgotten, and they are common on walls and fences everywhere in the summer months, but very difficult to distinguish from each other. In fact, the species in *Eupithecia* are a sort of standing puzzle to entomologists. One that appears in most gardens from May to August is named the Lime Speck (*E. centaureata*); its food, however, is usually outside the garden boundaries on such plants as the Ragwort and the Hemp Agrimony. Several of the species subsist on the flowers of the Golden Rod (*Solidago Virgaurea*) and some on the Clematis or allied plants, and a few on the leaves of trees.

About sixty species more, belonging to a variety of genera, complete the Geometrine group, most of the moths rejoicing in the English name of "Carpet," with some prefix expressing colour or character. Such names seem to have arisen from a fancied resemblance to patterns less common now than formerly. The caterpillars present much variety in appearance and tint; some are very sluggish, as also are most of the moths, though a few are distinguished as "highflyers" in the genus *Ypsipites*; the capture of these is rather difficult to effect, but they are harmless. In most counties the Garden Carpet (*Melanippe fluctuata*) is abundant, and it is almost the only species that can be regarded as a foe to horticulture, the principal food of the caterpillar being Brassicaceous plants. There are, unfortunately, two broods every season.—J. R. S. C.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CAULIFLOWERS from the first outdoor sowing will now be fit to plant out, and should have an open situation and well-enriched soil. Brussels Sprouts and Savoys from the early sowings should be planted out without delay; the latter will do 2 feet apart every way, but Brussels Sprouts should have 80 to 86 inches space. Beet must not longer be delayed in sowing if roots of fair size are required. Large kinds, as Whyte's Black, &c., may be had quite large enough by sowing early in June, especially in warm situations. Chicory also is liable to run to seed if sown

too early: the end of the present month—and it may be deferred until early in June—is a good time to sow the seed in warm localities. Another sowing of Runner and Dwarf Kidney Beans should be made. Celery, as it becomes ready trenches must be attended to, as when the plants are allowed to become large before being planted they receive a check which causes them to "bolt." Except for the very early crops single rows are preferable, and in preparing the trenches well-decomposed manure should be used plentifully and dug-in in a moist state, leaving from 4 to 6 inches of soil upon the surface. It is well if the transplanting can be done in moist weather. Advantage should be taken of showery weather to thin root crops; the plants not only draw more readily then, but those left for the crop are not nearly so much disturbed or otherwise suffer by the removal of the superfluous plants. Peas are not generally thinned; they, however, well repay any attention in that respect; thinning them to about 2 inches distance apart, the crop is rendered finer in quality, the plants more healthful, less subject to mildew, and less affected by drought, and is also more enduring where the plants are not excessively crowded. Leeks sown early should be at once planted out in well-manured trenches. Proceed with the planting-out of Vegetable Marrow plants, choosing for them a sheltered situation, but fully exposed to the sun, abounding in manure, and where water can readily be supplied in dry weather. Sow Cauliflower for the Michaelmas crop and for taking up when the heads are being formed, and protected for winter use. Veitch's Autumn Broccoli is a valuable variety, and much harder than Cauliflower; plants of it should be planted out the earliest opportunity. Tomatoes, plant out against walls. They may also be planted in good, rich, light soil in an open yet sheltered situation in rows 8 feet apart, and 2 feet asunder in the rows, training the plants to stakes 8 feet above ground. In warm situations they do well in that way, being well supplied with water in dry weather, and the rows mulched with short manure.

HARDY FRUIT GARDEN.

Fruit trees have very healthy and abundant foliage, yet it should be carefully examined for caterpillars, which if allowed to have their own way soon disfigure both leaves and fruit. Aphides also are very assiduous, and spread with amazing rapidity; they must be met by diligence in the application of insecticides and washing the trees thoroughly and repeatedly with the garden engine; if that fail diluted tobacco water must be had recourse to, applying it with a syringe during a calm evening. A solution of soft soap, 2 ozs. to the gallon, is a capital insect destroyer. The nets, canvas, or other means of protection should now be removed, the trees having sufficient foliage to protect the fruit from any frosts we are likely to experience after this. Peaches and Nectarines should be attended to in disbudding, and they, with other trees trained to walls, &c., must have timely attention in training-in the leading shoots, nailing or tying them in loosely so as to allow plenty of room for the swelling as growth advances. The thinning of the fruit of Apricots, Peaches, and Nectarines should be attended to, but do not be in too great a hurry; wait until the fruit is swelling freely, and then remove the smallest and those too crowded and badly placed. It will be well to leave a moderate number of extra fruit to allow for casualties, as from the imperfectly ripened wood of last year it is probable that more than an average will succumb to stoning. The very healthy state of the trees will allow of the fruit being left rather thickly without any undue strain upon their energies. Bush fruits are very heavily cropped in some districts, while in others the bushes are almost barren. Where it is intended to allow most of the fruit to ripen upon the Gooseberries, they, with the Currant bushes and Raspberries, should be mulched with short manure, especially in dry shallow soils. Similar remarks apply to bush and other forms of dwarfed Apple, Pear, Plum, and Cherry trees. The mulching should be applied when the fruit is fairly commencing swelling. A handful or two of bone dust sprinkled upon the soil around the trees before applying the mulch is very beneficial, especially to soil deficient of calcareous matter. Mulch Straw berries with long litter or some kind of material that will keep the fruit clean. If fine fruit are wanted "truss it up"—i.e., place forked sticks in the ground, so as to support the truss between the fork. Dr. Hogg, British Queen, and other choice large-fruited varieties are well worth any extra attention, thinning the fruit early. Three or four fruit upon a truss are sure to attain to a much larger size than twice the number. For producing "monster" fruit for exhibition purposes the centre or "king" fruit only should be retained. Water well in dry weather after the whole of the flowers are fairly expanded if the weather be dry.

FRUIT HOUSES.

Melons.—Some cultivators object to the taking of a second and third or more crops from the same plants. We could never see upon what the objection rested. It is alleged the fruit of the second crop is smaller and not so good in flavour as the first. Our experience is, that if the plants have been kept so dry during the ripening of the first crop as to impair the energies of the plants so as to render them unable to make strong young growths anew, they are of very little use for future bearing; but except in the case of extreme dryness and over first crop the plants are

as good or better than young plants. Any plants from which it is intended to take a second crop should be cut back to a healthy shoot emanating from near the collar of the plant, keeping the house rather closer, moister, and slightly warmer until growth becomes free, shading for a few hours in the hottest part of the day, and then remove the surface soil if only a little, and replace with fresh, giving a thorough watering with liquid manure. Buffalo horn manure we find a capital substance for promoting the growth of roots, and is a very handy and cleanly material. Its effects are very marked upon soft fruits, particularly Strawberries in pots. We use it in the proportion of about a tenth, calculating by bulk, to that of the compost. The primary shoots of Melons should not be stopped until they reach to within a few inches of the extent of the trellis, then take out their points. The laterals or side shoots should be thinned, removing every other early on alternate sides of the primaries, and when the flowers are fully expanded stop the shoots at one or two joints beyond each female flower. Let there be at least six or eight female blooms expanded at one time upon a plant before proceeding to impregnate them, continuing to impregnate daily until a sufficiency of fruit are set and commencing to swell freely. The essentials of a good set are activity at the roots, plenty of moisture there and a good warmth, but the surface of the soil comparatively dry, and a dry well ventilated atmosphere slightly higher in temperature. If the plants from which the fruit has been cut are decayed at the collar or infested with red spider to any serious extent it is better to replace them by young plants, removing all the old soil and commencing afresh. Earth-up the plants when the fruit is fairly on the swell, pressing it firmly. Syringe moderately early in the afternoon, and keep the shoots well stopped, avoiding overcrowding.

Pines.—Suckers potted last March will be in their fruiting pots; if not, the potting must not longer be delayed, for to keep them in small pots for any lengthened time has a weakening tendency. They should have a bottom heat of 85° to 95°. Be careful to raise the pots after the roots reach their sides, and not to over-water. All young stock will be growing freely, and should be attended to with regularity in watering, giving air, &c., slightly ventilating at 75° to 80° so as to draw condensed moisture from the leaves before the sun's rays fall powerfully upon them. Allow young stock plenty of space so as to secure sturdy growth. If too many fruit are ripening at one time a portion of the plants may be removed to a cooler house after the fruit commences colouring.

Figs.—Those ripened beneath the shade of Vines are generally at this early season insipid—worthless for flavour as compared with those in a light airy house; but much may be done towards improving the flavour by keeping the fruit free from moisture throughout the ripening process, with a free circulation of dry warm air, the temperature being maintained at 65° at night, 75° to 80° by day, rising to 85° or 90° with sun. When the present mulching is well filled with roots add another of 2 or 3 inches thickness of well-decomposed manure, it will help the trees in perfecting the second crop of fruit. The borders must not be allowed to become parchingly dry even when the fruit is ripening, and such a state of the soil with the fruit swelling would prove most disastrous to the crop and cause a rapid spread of red spider. Trees in pots from which the fruit is gathered should be well mulched with short manure, the syringe being plied freely twice a day.

Cherry House.—When the whole crop is perfectly ripe the chief consideration will be to prolong the season to preserve them fresh. Shading will do so, but it is only desirable when the fruit is exposed directly to the sun owing to the limited foliage. Free ventilation must be attended to, and in hot weather a sprinkling of the surface of the border in the hottest part of the day will assist in keeping the fruit plump. The roots must not be neglected for water, for dryness there is inimical to the development of the buds for the ensuing crop of fruit. Whenever necessary water copiously. Trees in pots will require daily attention. When the fruit is cleared off the trees syringe well twice daily, and do not expose them fully until the buds are well developed, nor remove trees in pots from the house until the buds are well formed. They may then be placed on ashes in an open situation and be duly attended to with water; the pots should be wholly or partly plunged. If aphids appear fumigate, being careful to have the foliage dry.

Orchard House.—Syringing must be resorted to every evening unless the weather be cold. The syringing is absolutely essential to keep the Peach, Nectarine, Plum, and Cherry trees free of aphids, which, however, is not always effectual, recourse having to be had to diluted tobacco water or fumigations, but care must be taken not to fumigate too strongly and to have the foliage dry. During fine weather the ventilators should be open from six o'clock in the morning until six in the evening, subject to later opening or earlier closing as the weather may determine. Abundance of water must be given to trees in pots, and those in borders must be well supplied with that element. Trees in pots should have a top-dressing of rich material; those planted out, if at all weakly, should be similarly treated. Thin out the fruit of Apricots, also

Peaches and Nectarines, which have set very thickly. Plums, Cherries, and Pears are the better of thinning, as a moderate crop of fine fruit is preferable to a heavy crop of inferior quality. In the case of trees with the pots stood upon borders the surface should be mulched 2 or 3 inches in thickness with rich manure, and the borders must be well attended to with water. It is advisable to adopt the mulching of trees planted out, because it checks evaporation, encourages the roots to the surface, and prevents the water from running off. Stop the shoots of Figs at the sixth leaf, and rub off or stop overluxuriant shoots on other descriptions of trees, so as to maintain uniformity of development—symmetrical trees.

FLOWER GARDEN.

Planting may be proceeded with, commencing with the hardier descriptions of plants, such as Verbenas, Lobelias, Pyrethrums, Calceolarias, Gnaphaliums, and the hardiest Pelargoniums, deferring planting such as Coleus, Iresine, &c., until the early part of June. It is of infinitely greater importance to have the plants well prepared than to plant out because the time of year has arrived for doing so. The condition of the plants and the state of the weather must both guide the planter. Some plant very shallow, when the plants are withered up in a short time under powerful sun; others plant deep, and the plants then do not start freely, such as Calceolarias and Pelargoniums going off at the collar. The right way is the mean of the two. Water well at planting to settle the soil well about the roots, and a sprinkling overhead in the evening of hot days will often be found better than heavy waterings, making the soil sodden and cold. Stocks, Asters, Phlox Drummondii, Marigolds, and other half-hardy annuals should be planted out as they become ready, they transplanting more safely in a small state than when large. A dull day should be chosen, watering them well, and dusting with quicklime or soot as a precaution against slugs. Dahlias should also be planted out. Now is a good time to trim Box edgings, doing it in moist weather, or the edging will have the appearance of being scorched if it be done in bright dry weather. Attend to the training of climbing Roses, Clematis, and other climbing plants; and if any are infested with aphids syringe with soft soap 2 ozs. to the gallon of water, adding a pint of strained tobacco juice to each gallon. In dry soils a mulching should be given of well-decayed manure or spent hops and liquid manure whenever the weather is hot twice a week. It is absolutely necessary to render enjoyable the rich floral display now afforded by Lilacs, Rhododendrons, Azaleas, Brooms, &c., that the grass be kept frequently mown and the walks clean and well rolled, weeds being kept under as they appear. What a truly gorgeous display is afforded by double Whin! Masses of it by the acre outvie its compeers.

PLANT HOUSES.

Greenhouse.—Primula cortusoides vars. as they go out of bloom should be removed to a cold frame. If stock be wanted they may be divided, potted in rather strong turfy loam with a little leaf soil or well-decayed manure, placing them on ashes and shading from bright sun. P. denticulata, P. nivalis, P. intermedia, and other of the Alpine section may be divided, potted singly in 4 to 5-inch pots, and receive similar treatment to P. cortusoides vars. P. verticillata sinensis treated in a similar manner forms nice plants for next season's flowering. Any that are required for seed should be continued in a light airy position until the seed is ripe, when they may be treated as before described. Lachenalias should be continued in a light airy situation, having lessened supplies of water until the foliage become yellow, when watering must cease, only affording a little occasionally to prevent the soil becoming dust dry. Tropaeolum Jarratti tricolorum should be gradually dried off, and when the foliage is decayed take the tubers out of the soil and keep them in a dry cool place through the summer. Cyclamens place in a cold frame upon ashes and water so as to keep the soil moist, and shade from bright sun during the hottest part of the day. Seeding Cyclamen sown early and potted or pricked off should be shifted into larger pots or potted off singly as the case may require, and may be stood in a cold frame, keeping them close, moist, and shaded until growing freely when more air may be admitted. Primula sinensis vars. pot off, as they become ready. Similar remarks apply to Cinerarias, both being kept rather close, moist, and shaded until established. They do best in cold frames. Humea elegans may now be raised by sowing the seed in fine soil, just covering the seed and placing in gentle heat, removing the pot to a cold frame when the seedlings are up. Chrysanthemums move into the blooming pots between now and the first week in June, it being highly prejudicial to the plants to allow them to become root-bound, particularly in the early stages. They do well in turfy loam with a fourth or fifth of decayed manure and a sprinkling of bone dust, about a tenth. The pots may be crocked with crushed bones, placing one large crock over the hole in the pot. Eight and nine-inch pots answer well for Pompones; 9, 10, and 11-inch pots for the large-flowered varieties; for single blooms 9-inch pots are large enough. The form of training must be at once determined upon. The flat form is most resorted to for exhibition, but the more upright is best for general purposes. Stopping the shoots should not be practised after the early part of June, those for

specimen blooms not being stopped at all. Arrange the pots on a bed of ashes in an open situation but sheltered from winds, affording the plants plenty of room, and never allow them to suffer by want of water. Pelargoniums as they come into flower must be scrutinised for aphids and the plants if necessary be fumigated, for if the insects are left on until the flowers expand and then fumigated a majority of the petals will fall. Assist late-flowering plants with weak liquid manure, also zonals, having the pots filled with roots, and forwarding those as yet in small pots by shifting into larger.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Spring Catalogue of Plants.*

E. G. Henderson & Sons, Pine Apple Nursery, Maida Vale, London.—*Catalogue of Flowering and Ornamental-foliaged Plants.*

TO CORRESPONDENTS.

GOLD WEED (X).—We are making inquiries, and will publish the information as soon as our correspondent has ascertained the botanical name.

CUCUMBER GANGRENE (R. E. Knechtbull).—You will find an account of this disease in vol. 33, page 73, of this Journal. There is no cure, and the sooner you destroy the plants and clear out the soil the better. Renew the bed with soil from a fresh place.

ARRANGEMENT OF SUMMER BEDDING PLANTS (Ramalho).—We do not like your idea of independent patches of colour in the long scroll bed; the effect would be heavy and lack expression. Taking your own materials we would make a row of strong plants of Geranium Christine right along the centre, a row of Coleus on each side of it, and put a row of Mrs. Pollock Geranium outside both rows of Coleus, taking care to keep the flowers picked off Mrs. Pollock, and if you could continue to secure enough plants of Lobelia pumila grandiflora to make a chain of its charming blue miniature mounds outside Mrs. Pollock the effect would be excellent. Relegate the scarlet Geranium and Perilla to some other part of the garden, and plant the two detached beds with Verbenas and Calceolarias as you propose.

PEACH LEAVES BLISTERED (Idem).—The blistering of your Peach leaves is caused by exposure to cold winds. Protect them until milder weather ensues, and the blistering will cease. "Curl" is quite a different thing. It is caused by aphides, which, attacking the under surface of the leaf, induce a contraction of its tissues, hence the deformity. Get rid of the aphides by syringing and sponging and the leaf will become healthy, but it will always be a deformed leaf and never attain its full size. Blistered leaves, on the contrary, can never become healthy, and must be removed with caution, for it is usually the outer and most exposed ones which suffer, and while these are found to afford some protection to the under leaves retain them.

GLOIRE DE DIJON ROSE.—Mr. W. H. Lyons informs us that in his garden near Lisburn, in the north of Ireland, this flower has been cut, as well as Marchal Niel, ever since the 1st of May.

SEEDLING PANSIES (Old Subscriber, Merthyr).—The flowers received are medium-sized, well formed, have great substance of petal, and have rich colours—dark selfs. They are all good, but not large enough for the florist's standard. The varieties are well worthy of preservation for garden decoration.

WATERING AMARYLLISES (S. B.).—Amaryllises require to be copiously watered when in full growth, but it is seldom necessary to place the pots in pans of water. If the pots are excessively crowded with roots and the plants cannot be examined frequently a little water may be kept in the saucers in which the pots stand, but we only advise it as the lesser of two evils. The plants must have a very light position, and the roots must not be dry.

LIQUID MANURE FOR CUCUMBERS (G. S.).—The drainings from a hotbed, from a cowyard, and a solution of guano, are all good for applying to Cucumbers when they need a stimulant. It is impossible for us to say to what extent the drainings should be diluted, for the liquid may be much diluted already by the rains, or, on the contrary, it may be very strong. Use your own judgment, and rather err on the side of applying the liquid too weak than too strong. Half an ounce of guano dissolved in a gallon of water will produce a stimulant quite strong enough for Cucumbers. Apply the drainings and the guano water alternately when the plants require more support than the soil affords them.

NECTARINE FRUIT FALLING (W. B.).—The cause of the fruit of your Pitmaston Orange Nectarine falling is due to imperfect formation of the seed or kernel, a process very often confounded with but distinct from stoning, which does not take place until a later period, when the fruit remains stationary almost for weeks, and when the stoning is completed the fruit swells rapidly. It is very similar when the seed or kernel is being formed; the fruit remains stationary for about a week, and either then assumes a sickly hue, ultimately dropping, or swells rapidly up to about half size, when the stoning commences, and occupies from four to six weeks. Yours have failed at the earliest stage. We have invariably found it a consequence of imperfect ripening of the wood, the trees being very vigorous and apparently very healthful, and, as your gardener says, does not arise from a deficiency of water at the roots, but is mostly resultant of the foliage being overcrowded. The foliage if we mistake not will be very fine. The shoots must be further apart than were the foliage smaller, so that the sun and air may have free access to the leaves. It is a common error to lay in too much wood without regard to crowding or discriminating between the requirements of medium-sized and large leaves. Keep the shoots thin, let the sun and air have access to them, thereby securing the thorough ripening of the wood, and your tree will return to its fruitfulness as before.

ZONAL PELARGONIUMS WITH DIVIDED TRUNKS (N. C.).—It is not an unusual occurrence, usually arising from too rich soil and wet. Turn the plants out of their pots, remove at least a third of the soil, and repot in turfy loam with a fourth of thoroughly decayed hotbed manure and a free admixture of sand—about a sixth. Shade for a few days until the potting is recovered from, stopping the shoots when the roots are working freely in

the fresh compost, and shift the plants into pots a size larger when the roots reach the sides of the pot and before they become very closely matted, affording the plants a position near the glass in a light airy house.

TREATMENT OF "LA BELLE" CARNATION (Idem).—Report the plants but do not disroot them; merely loosen the sides of the ball and remove any loose soil from the sides and the surface. Pot in rather strong turfy loam, employing a pot 2 inches larger in diameter than before, potting firmly and draining well. Do not cut back the shoots but train them to a trellis, which may be formed of small stakes painted green in the form of a column, to which the shoots can be trained with care. The plants may be plunged in ashes outdoors in an open but sheltered situation, removing them to the greenhouse in late September. It is one of the most continuous-flowering of Carnations. Young plants may be stopped, but it must not be practised after this period if the plants are to bloom well the ensuing winter.

CUCUMBERS IN MARCH AND APRIL (Primrose).—You may grow Cucumbers in pots so as to have fruit in your stove at the time named, it being kept at a temperature of 70° to 65° at night, 75° by day, rising to 85° with sun and air, which, however, is too hot for stove plants generally in January and February, the seed of the Cucumbers being sown early in January. The vinery is not suitable, but we do not see why you could not have Cucumbers early in April if you were to take care of the litter during the early winter and supplement it with tree leaves. Sow in January, the first week, and make up a bed so as to receive the plants early in February.

RED PAINT FOR GREENHOUSES (Subscriber, G.).—Your wholesale condemnation of "red oxide of iron" paint is unwarrantable, and your deductions merely imaginative. It does not at all signify what the colour of the paint is that is used upon the outside woodwork, for the obvious reason that the solar rays do not pass through the woodwork but the glass, and, though the rays are refracted and reflected, it is only those that pass through the glass that can have any effect upon the plants in the interior of the structure. All paint comes off where the wood is damp. We agree with you in red being an unsuitable colour for greenhouses, but instead of the orthodox white we prefer light stone colour for the external woodwork, using white for the interior, with drab for the stages.

NAME OF PLANT AND PROPAGATION (A Constant Reader).—The plant known in your locality as "japonica" is, from the description given, Cydonia japonica, or Japan Pear, one of our handsomest spring-flowering shrubs. It may be propagated by layers made in autumn and allowed to remain on for twelve months before being detached; also by suckers, cuttings of the roots cut into lengths of 3 to 6 inches and inserted about 2 inches deep in light soil in a warm situation, and occasionally by seeds. Layers are the best, cutting about half way through just below a joint, and burying the notched part 2 or 3 inches deep in the soil and there secured with a peg.

GREEN RANUNCULUS (Rev. S. A. Brennan).—Green centres in the Turban Ranunculus have been very prevalent this season. We saw a bed in a friend's garden in which the whole of the flowers bloomed with green centres. We do not know what has caused this unusual phenomenon, but it is very frequent this season.

WATERING MELONS (A Subscriber).—While the fruit is swelling you can hardly give too much water, a copious supply being poured upon the soil at least once a day in hot sunny weather. When the fruit is full grown and the process of ripening begins it will lose its green hue, and this will be an indication that the time to cease watering has arrived. Attend closely to this, or the fruit will split and its appearance be spoilt.

GRUB IN APPLE TREE (H. P.).—It is the larva of the *Zeuzera aesculi*, Wood Leopard Moth.

CORDON APPLE TREE UNFRUITFUL (G. C.).—When the spring shoots are stout and strong prune or pinch them off to about four leaves. Neither prune nor pinch the midsummer shoots but let them grow, and early in September give each shoot a twist at about 4 inches from its base, taking care not to break it, and turning the tip downward. This gives a check to the growth, diverts much but not all of the sap into the buds between the base and the "twist," causing them to become plump and prominent without actually starting into growth. Enough of the sap passes through the bruised tissue of the "twist" to keep the turned-down ends alive, and they are not cut off till the leaf falls, which will happen somewhat early, and by the end of the month you must open a trench about a yard from the stem and all round it, going quite under it to make sure that the whole of the roots are severed, then replace the soil. This treatment will promote the speedy formation of blossom buds.

NAMES OF PLANTS (J. E. S.).—*Rosa alpina*. (A. B. C.).—3, *Selaginella Martensii*; 4, *S. Braunii*; 5, *S. Kraussiana*; 6, *S. cuspidata*. (M. H. M.).—*Chrysanthemum coronarium*. (Jean).—1, *Valeriana pyrenaica*; 2, *Stellaria Holostea*; 3, *Scilla patens*. (J. C.).—*Alaternia* sp.; 2, *Berberis Darwinii*; 3, *Coronilla Emerus*; 4, *Kerria japonica*; 5, *Candollea cuneiformis*. (F. Q.).—A double-flowered variety of *Saxifraga granulata*. (Holton).—1, *Prunus Padus*; 2, *Stapelia pinnata*. (J. S.).—*Petty Whin* (*Genista anglica*) and *Marsh Marigold* (*Caltha palustris*). (A. M.).—*Franciscea latifolia*. (A Subscriber).—We cannot name plants from leaves only, nor so many specimens. We have requested subscribers not to send more than six.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE REARING OF CALVES—(Continued).

WE must now refer to the second part of our subject, that of rearing either heifer or bull calves with the object of being fed and fattened for slaughter in the future as beef upon the principle of early maturity. Even under this heading we have two matters to consider—viz., whether the calves will in the future be required for grazing in the open pastures, or required to be box or stall fed and kept under cover entirely, as the latter practice is often adopted with great success, particularly upon farms composed chiefly of arable land. In our former notes we made

comments upon rearing the calves up to four months old; we now propose to refer chiefly to their treatment after that time and until they become twelve months old, at which time they leave their calfhood and are then commonly called yearlings. When it is intended that the calves should be grazed in the open pastures it must be upon land bearing grass of sufficient quality to fatten them, with only a slight amount of assistance by the use of oilcake or other feeding materials. We, however, recommend that the calves should under any circumstances be housed or yarded at night, as this will be the time and opportunity to give them their artificial food both at night and morning, and the surest means of preventing the disorders and complaints to which they are liable when left to graze in the pastures night and day continuously. The most serious complaint, however, to which they are liable, and particularly the heifer calves, is the "black leg" or "quarter ill." This disorder is known by different names in different localities, and is one of the most fatal maladies to which young cattle are subject. It is very rare that any cure is effected, because under ordinary circumstances it cannot be discerned soon enough; therefore we must look to precautionary and preventive management. In our own experience we formerly lost nearly every year some of our best calves when they were left in the meadows at night, but after adopting the before-named plan of housing at night we have never lost an animal from that complaint. With regard to the bull calves to be fed and fattened as steers in the future, they should be castrated at about a month or five weeks old if healthy and strong, and the operation should always be performed by a practised veterinary and whilst they are in house, and they certainly ought not to be allowed to go into the pastures until they are entirely recovered from its effects.

In referring to the matter of feeding calves under cover to be made out as beef in the future, we advise that they should be accommodated in boxes about 12 feet by 12 feet, and we have on various occasions fitted-out a number of capital boxes in old barns, which we have found generally of sufficient width to make a double range of boxes with feeding path in the middle. This affords excellent boxes made with fir poles about 18 inches apart, the feeding path being raised, and the floors of the boxes sunk about 18 inches and filled with earth about 12 inches in depth; the manure then may be allowed to accumulate with advantage. As soon as the calves are able to do without milk or its liquid substitutes, and are able to live upon green fodder, they are removed from the calf-pens and placed two or three together in the boxes and littered with straw as cleanliness requires, and according to the time of the year they will be fed upon green fodder, such as rye first, followed by trifolium, tares or clover, and finally with roots. Care must be taken to have within reach a bundle of clean straw and a lump of rock salt, these articles being the great correctives of their health whilst feeding on succulent green fodder. Some parties, however, adopt the plan of cutting into chaff a mixture of straw and green fodder, to which plan we cannot object. It is, however, more expensive and not so simple in management. Chaff offers a good opportunity to mix with and give the cake or meal, as in the absence of the roots such as carrots, mangolds, &c., with which we usually mix it, it is found a good substitute. As the calves advance in age the cake and meal are increased. Whilst they are living on green fodder they get it *ad libitum*, and receive at first about 1 lb. of cake and 1 lb. of meal per day. As the season advances and they begin to receive roots the quantity of cake and meal may be doubled; but at no time after they once take to their green fodder or roots are they allowed hay, as this would be found to absorb the profit and injure the health of the calves also, for since we have adopted the method of straw feeding we have found great uniformity in the health of the animals. The quantity of roots given after the calves commence eating should range between 20 lbs. per day to 40 lbs. per day each until they are about twelve months old, the roots being cut with Gardener's cutter and the meal always mixed with the cut roots. In this way each kind of food is more beneficial to the calves, and when only fed twice a day they have plenty of time to lie down and digest their food, and in the interim will eat a good portion of clean sweet straw, and then return to the feeding troughs with a good appetite. Upon this system of management the calves at the time they are twelve months old will be found, not only in the most healthy state, but will also exhibit first-rate condition both as regards quality of meat and weight for age, having been fed in the most economical manner, and will have retained their calves' flesh, so advantageous as a foundation for successful feeding in the future. We will here quit the subject because, having remarked upon the method of feeding the calves, we propose on a future occasion to refer to the best system of feeding the animals fit for the butcher at the earliest period.

We have now to refer to the remaining part of the subject—viz., the rearing of calves with the object of being sold and killed for veal. The keeping a dairy for suckling used to prevail to a much greater extent than at present in consequence of the greatly extended demand for milk in the metropolis and other large towns. When the suckling of calves used to be carried out as a system,

called a suckling dairy, it used to be observed that veal at sixpence per pound paid as well as the butter at a shilling per pound; and as the value of butter and veal bears about the like proportion there is no reason why a suckling dairy should not pay well at present, particularly in some districts which are remote from railway stations, and in cases where cheese or butter making may be inconvenient. The chief difficulty is sometimes found in obtaining a supply of calves sufficient to meet the requirements of a dairy of considerable extent. The supply would, however, be readily obtained in a cheese-making district, as the calves are usually disposed of at a few days old, at which age they are generally bought up for filling vacancies in the suckling dairy and continuing the succession, so that all the milk from the cows may be converted into veal. When the calves first arrive they require very careful attention, because we have often taken them after being starved for twenty-four hours, in which case we always put them to a cow which has nearly been sucked dry by another calf. For the first week we always put two calves to one cow, and gradually advance them to maturity as veal; but in advancing them care must be taken that they receive no check in their condition either from shortness of milk or other assistance, for it is desirable in some stages of their growth that they should receive artificial food given as balls composed of mixed oilcake and oatmeal. In selecting calves for making veal the breed of stock is very important. Either Shorthorns, Herefords, Devons, or Sussex answer very well; but care should be taken that no cross-bred stock having Channel Island blood in it should be purchased, because this breed are not only poor doers and slow growers, but when killed often die of a yellow colour, which is entirely objectionable to the butcher. It is at the same time important that the cows for a suckling dairy should consist of cows of the sorts above named, the Shorthorn being the best of all, not only because they give the most milk, but because their milk is of a comparatively poor quality, which is essential in making a good veal calf. It is an admitted fact that quantity is of more consequence than quality of milk in suckling calves for the butcher. We have often noticed that a good butter-making cow makes comparatively but a poor calf, which often proves of a yellow colour when killed. As a matter of profit a suckling dairy pays quite equal to the other methods of turning milk into money, and, when properly attended to by careful observation of the health of the calves and furnishing them with good and healthy pens, similar to those which we have described. For veal calves the pens, however, should be as dark as they can be made consistent with a sufficient ventilation and pure air; the calves should also be tied separately and suckled at regular intervals, they will then in the interim lie quietly and take more sleep, which is so essential in all cases of economical management of a suckling dairy. Good Shorthorn cows ought to fatten five or six calves during their milking period, probably worth £5 each, particularly if the calves get the artificial food balls as recommended. We have no doubt that cows well fed will continue to give milk longer and give more of it whilst suckling calves than under any other system, for it must be admitted that the calves are the best milkers and never leave injurious deposits in the udder. A suckling dairy will, however, require constant and unremitting care, but it is attended with less trouble and expense compared with butter and cheese making.

WORK ON THE HOME FARM.

Horae Labour is still required on the fallows in preparation for Swedish turnips, or mangold and carrots if not already sown. Nothing, however, is more injurious to the cultivation for Swedes if the land is clean than too much ploughing, because it makes the land too hollow, in which case the grub and wireworm often do serious injury to the young plants, besides which, in the event of settled dry weather setting in, the ground would soon be too dry for the seed to vegetate. We have experimented many years ago upon this point. The horse-hoeing of beans and peas, also of early potatoes, should be done, the hand-hoeing following, so that the weeds may be destroyed in their infancy. Green fodder crops are now available for horses, cattle, and pigs. On the home farm, whilst the sheep are on the pastures, not only the green fodder crops may be cut for feeding but the clover crop also, because an acre of clover is far more valuable cut for feeding cattle under cover than by feeding it off with sheep; besides, the wheat crop succeeds better after clover cut twice than it does when the clover is fed off by sheep during the summer. This matter is explained by the fact that under the scythe the roots of clover increase immensely, even if the clover is cut three times or cut once and left for seed; whereas sheep in feeding clover injure the growth and succession of grass, and thereby check the increase of the root. To return, however, to the feeding of stock. We use the trifolium for feeding the horses, the fatting bullocks, the yearling heifers and steers, also the calves from eight weeks old and upwards, the breeding sows and store pigs of all ages. The fatting bullocks may have in addition about 20 lbs. of cut mangold each, mixed with 4 lbs. of cake meal; the yearlings about 10 lbs. of mangold with 2 lbs. of cake meal, and this is very cheap feeding considering the progress the animals will make under this mode of management. At the same time wherever

the consumption of green fodder is going on the value of the manure will be very great when the cattle are fed under cover, either in boxes or in sheds, especially if the floors of the sheds are well covered with earth before the cattle enter them and afterwards properly littered. Rye if gone too far for green fodder may be cut and cleared for the succeeding crop, and tied up into sheaves and reserved for straw; or it may be cut up and after a few days carted to rick for the purpose of using as rye hay, for which it is very valuable in the winter months, and much better than hay, the produce of pasture land, for the feeding of fattening cattle in conjunction with roots, meal, &c.

The question now arises as to the best crop to sow in succession after the rye, trifolium, vetches, &c., are cleared. This must in a great measure be decided on by the probable requirements of the cattle next winter and autumn. If mangold is wanted it comes well after rye or trifolium sown any time in the May month. If a provision is required for dairy cows, &c., of green fodder in the autumn trifolium of the early sort dragged in now on the rye stubble will be fit for cutting at the end of twelve weeks. After trifolium is cleared vetches and oats may be sown as a mixed crop for horse fodder. This also will come fit for use at a time when the clovers are past the best. Vetches and tall rape may also be sown after trifolium, it being the best of food for milch cows in the autumn. Cabbages may also be planted at one ploughing after trifolium, manure from the farmyard being laid out and raked into every third furrow, the cabbage plants being set on the furrow over the dung, or guano may be strewn in every third furrow instead of dung.

Hand Labour.—Men may now be partly employed on the home farm where there are many fences with banks and ditches, for in such cases much strong grass, wild parsley, hog weed, &c., will be found, which being cut now from the banks, ditches, and borders will furnish capital food for young cattle, pigs, &c.; in fact there will be two cuttings in the summer if cut at the right time. This plan not only furnishes food for stock, but it is in fact trimming the hedges and turning to good account the hazel boughs, brambles, &c., which if left until the autumn before being cut become objectionable by seeding the adjoining land with seeds of the coarse grasses and weeds. Women will still be required in the fields weeding the Lent corn, also in couching, and we have oftentimes found some of the strongest of them earn good wages at hoeing peas, beans, &c.; also the first flat-hoeing of mangolds is work which they can often do with advantage, particularly in some districts where men for field work are scarce.

THE POULTRY CLUB.

The first meeting of the regularly constituted Committee of the Poultry Club was held on Tuesday the 14th at the Charing Cross Hotel. There were present the Hon. and Rev. F. G. Dutton (Chairman), the Hon. and Rev. A. Baillie-Hamilton, T. C. Burnell, A. Darby, and O. E. Cresswell (Hon. Secretary). The Honorary Secretary presented the list of Officers and Committee as elected by the members of the Club, and it was resolved that his analysis of the votes be taken as correct. The Committee so elected are as follows:—President, the Hon. and Rev. F. G. Dutton; Vice-President, the Hon. and Rev. A. Baillie-Hamilton; Treasurers, H. Radclyffe Dugmore and Horace Lingwood; Hon. Sec., O. E. Cresswell; Committee, R. A. Boissier, T. C. Burnell, A. Darby, J. K. Fowler, S. Matthew, E. Pritchard, Rev. W. Serjeantson, and L. Wright. A communication was read from Mr. Lewis Wright concerning his election to the Committee. While wishing all success to the Club, and fully appreciating the wishes of the large number of members who voted for him, he thinks it best for the Club to be independent of his personal service. Mr. R. C. Horsfall will therefore be on the Committee. Mr. Cresswell then, as Treasurer *ad interim*, stated that the subscriptions already paid to the Club amounted to £84 18s., and that the amount expended was very trifling, there having been no advertisement of the Club, as is usual on the formation of such societies.

It was resolved that the Treasurers be requested to open an account in their joint names with the London and County Bank. It was further resolved that the list of the Club with officers and Committee should be printed and published, and that the rules of the Club should be printed. Some rules for the good management of poultry shows were discussed and agreed upon, and it was resolved that committees of shows be invited to hold their shows under the patronage of the Poultry Club. Further resolutions were passed concerning communications between the Hon. Secretary and the Royal Agricultural Society. Several new members and associate members were elected, and the next Committee meeting was fixed for Monday, June 10th, to be held at the Clarendon Hotel, Oxford, on the first day of the Bath and West of England Society's Show there.—C.

PIGEONS—HINTS TO YOUNG AMATEURS.—No. 3.

I STATED at the end of my last paper that I would next speak of the best food for Tumblers, also of their indoor management and most suitable home. Flying Tumblers are wonderfully

healthy birds. Whoever saw one ill? Catch them when you will they are always plump in breast and bright in eye. They are the happy medium in size between that smallness which brings delicacy and that lumbering bigness which seems to knock itself to pieces from its oversize. I was once talking to an old Peninsular and Waterloo veteran, and asked him whether he kept his health during war time. He was a neat-made, medium-sized man, probably 5 feet 8 or so, with capital shoulders for a knapsack, and he was also in the line, the common marching, or, as they were jocularly called, "mud regiments." He told me that he and the men in his regiment were well enough, and few of them ever in hospital; but added, "it was those big guardsmen that knocked up; they were soon done for and in hospital, and more of them fell out on the march than any other regiments." This was told to me by the old linesman as he was nailing up fruit trees, for he was, before he enlisted and after his discharge on a pension, a jobbing gardener. The medium size is the best for health in man, and beast, and bird. The heart has not so much work, and the limbs are not so lengthy and straggling, while the size is sufficient for a healthy development and for robustness, not being over-small and delicate. So of our little plump-bodied middle-sized Flying Tumbler; not a big hulking roopy Pouter, or a tiny bit of delicacy called a Short-faced Tumbler. I know no other Pigeons so healthy, except perhaps the Dragoon, so therefore hints as to diseases and cures are not needed. Supply your Flying Tumblers with a pan, a shallow one, of water for a bath; let it be where the morning sun shines on it, and Mr. and Mrs. Tumbler and their very numerous progeny, excellent to eat if you cannot sell them, will bathe to their delight. Then there is another kind of bath—the air bath, which they are sure to take, and which puts every feather in its place, and braces while it exercises the little wings.

But what as to food? In this matter you need not go to great expense. Having their liberty Flying Tumblers are sure to pick up much—many a crumb at the back door, and in harvest time mine used to delight to get on the roads where the harvest waggons passed, and very little food they then needed. Flying Tumblers will do well enough on a mixture of peas, Indian corn, and barley. I never used a hopper for long, simply because of the mice; they would get in and spoil the food, besides eating a quantity, and, worse still, make the whole place smell of mice.

Next as to home for Tumblers. Put aside all thought of a wooden house on a pole—those cruel things; scorching in summer, starving in winter, in which no Pigeons prosper or rear sufficient young ones to pay for one-half their food. Then those triangular wooden boxes on a south wall are rather better, but poor things still, and you cannot have any control over your birds. A small place inside a building with a hole or holes in the wall for ingress and egress—such a place, fitted up with neat places a foot wide and deep, does admirably. If you can give much room do, the more the better, the fewer eggs broken, and the more young reared. A shut-down lath or wire door at night for safety from the cats, for Miss Puss and Mr. Tom are very partial to young Pigeons. Some odd corner of a building may easily be fitted up for a few Tumblers. If on the ground floor it will be easier to clean, and make a place to stroll in during a shower. I always notice that fanciers who have their birds on the ground floor pay them most visits. A ladder to climb has a tendency to make fanciers less attentive than they should be; though not always, for I know London fanciers who have built wooden huts for their birds on the very roofs of their houses, and get twice a-day there with their Pigeons, watching them with a binocular, so as to see and distinguish the tumbling of some new purchase. Wonderful home love and home knowledge must these little birds have who come straight down to their little homes, knowing the place exactly amidst the miles of roofs stretching beneath them. There they are up mere specks in the air—then down, down, down with no mistake to their own little wooden hut on the high roof—

"Type of the wise, who soar but never roam,
True to the kindred points of heaven and home."

A wired-off corner of an outhouse does nicely, say 6 feet square. Being wired, or partly so, you can have a nice view of the birds without going inside. See them on their nests, notice who are nesting, what birds are sitting, which are absent, &c. Those who cannot easily get to see or watch their pets do not have nearly so much enjoyment of them as those who are frequently with or near them; and although Tumblers will live anywhere, they do best where best care is taken of them. A plan of a Tumbler house, a very good one, was given in vol. xviii. of this Journal, page 818, and as I am sure there are many beginners, many in our infant fancier classes, who were not readers of our Journal so far back as April, 1870, I will ask the Editors to be good enough to reproduce the sketches and description of the pen for Flying Tumblers to which I allude.—WILTSHIRE RECTOR.

It often happens that there are about one's premises various nooks and corners (in an outhouse, loft, &c.) which, with a little judicious fitting-up, can be rendered available for this purpose; but should the beginner have no such place at his disposal and a pen has to be constructed, the following is the plan I would recommend as best adapted to the purpose. At the same time, as

regards the internal arrangements of any suitable place that he may have upon his premises, I should advise the adoption, as far as possible, of the principles stated beneath. Perhaps my ideas will be best conveyed by the following sketches.

Fig. 60.

The above figure represents the external appearance of the pen I recommend. It should, if possible, be placed against a wall facing any point between south and west, for the obvious reasons of being sheltered from cold winds and to have the benefit of the sunshine. The dimensions are 6 feet square, with the exception of the back, which is 7 feet high. It should have a boarded floor, either raised a little from the ground or the foundation dug out and filled with dry ashes. There should be a pane of glass in the roof, and two holes cut in front and fitted with bolting wires, to be closed up with a ledge working on hinges, to ensure protection from cats. Provision, of course, should be made to ensure the necessary ventilation, and this can be done by boring holes as represented in the door, and at other places near the roof. The latter can either be tarred or covered with roofing felt to keep out the wet.

The internal arrangements are represented in the following sketch.

Fig. 61.

Five shelves, each a foot wide, should be placed against the back of the pen. They should be 1 foot apart, and, with the exception of the space between the floor and the lowest shelf, should be divided in the centre by a partition. In front of these shelves should be nailed four boards, also a foot wide and 5 feet long, one at each side of the pen and two down the centre, all reaching from the top to the bottom shelf. This will give breeding places for ten pairs of birds; these will be 3 feet long by 1 foot wide and 1 foot high, with a blind at each end behind which to put the nest pans. The two spaces between the top shelf and the roof should be fitted with lath fronts made to hang by hinges from the roof, and these will be found most useful either as pairing cages or to pen birds in. The floor of the pen should be left entirely free with the exception of the water bottle, the mortar pan, and the salt, all of which should be placed under the bottom shelf to keep them clean. Each side of the pen should be fitted with perches made in the well-known triangle shape. A little strip about an inch wide should, however, be nailed across the angle to prevent

the sharp edge from injuring the feet of the birds, and to enable them to rest comfortably. The perches should be from 3 to 4 inches wide, and placed about a foot apart. They can easily be fixed by nailing them to a strip of wood, and so screwed to the side of the pen.

I have omitted to state that a door made of stout laths should be fixed to the pen in such a manner that the outer door may shut over it. This can easily be done by nailing a lath on each side of the door inside the pen; one to hang it on, and the other to fasten it to. The inner door should be made to open outwards the same side as the outer door, by placing the perpendicular laths about an inch nearer the centre of the doorway than the width of the outer door. This inner lattice door is to give light, air, and sunshine to the birds; the outer door, of course, to lock up safely at night, and to keep the birds warm and comfortable in cold and wet weather.

A pen on the above scale is calculated to accommodate from thirty to forty Pigeons, and the cost of its erection will be about £2, which again may be diminished to somewhere about half if the fancier is at all handy with the hammer and saw, and able to erect it himself. Of course it is not intended that the pen should of necessity be made to the dimensions I have given. Everything, as I said before, depends upon the intentions of the fancier as regards the number of birds he intends keeping, &c.; but whatever may be the dimensions of the pen, the above principle should be adhered to as best calculated for the kind of birds of which this article treats.

It may be as well to state here that the inside of the pen should be well limewashed once or twice a year, and the floor and breeding places kept well sprinkled with sand, which will render it healthier for the birds and easier to clean out. I would recommend that the latter process should be performed daily. It can be done in the following manner in five minutes, and the little extra trouble will be amply repaid by the better health and breeding of the birds, and the pleasure of seeing them always clean. Scrape out the dung from the shelves on to the floor, and then, having scraped all into a heap, pass it through a fine riddle, taking the excrement away and using the sand again.

THE SELECTION OF A BREED IN RABBITS.

THERE are about half a score of Rabbit varieties all differing from one another in many important respects. When a person wishes to commence breeding he is met with this array of varieties, and does not know what kind to begin with. He cannot do better than commence with a pair of common hutch Rabbits costing about 2s. or 2s. 6d., and after he has learnt a few lessons in breeding and rearing, at the expense probably of the constitutions of the animals selected for experiment, he may then try with some more valuable specimens, choosing those that may be specially suited to his Rabbit house and hutches. Some varieties are very hardy and others equally delicate. A short list of the characteristics of the various kinds with their requirements and nature will be of great assistance in the selection. It is very necessary that there should be plenty of room for the new comers, so that they may not be crowded at all. Crowding is very unhealthy, and very often the cause of many diseases. Therefore it is best to get the hutches properly arranged and then to bring the Rabbits to them. If you select Lops you must have heat. Look carefully around you and see if the provision of heat is likely to cause very much trouble, and if it is the scheme had better be abandoned definitely, as it does not pay to keep them without heat. If there are facilities for heat it will be very interesting to keep Lops, because they vary more than any other variety, and are consequently susceptible of a great many experiments. Still those who keep them must not be surprised at failure, nor must they be disappointed, because Lops are most obstinate animals, and they often refuse to breed.

When the means at hand for providing comfort are very limited it is better to keep a hardy variety that does not want many comforts. A Silver-Grey section will answer pretty well, but even this breed should be kept a little warm if the fur is wanted to look very pretty. They are very handsome and useful, and the strongest and hardiest variety that is known. They may be bought cheaply if slightly mismarked, and good specimens may be bred from these. They are good breeders, and as there is a good demand for the young they may be sold at a remunerative price. They are affectionate and gentle, and make good pets for children. Angora Rabbits are much more delicate. They have long white wool, which is troublesome when moulting, as it gets on clothes and is difficult to shake off. The breed requires a little heat, as they are delicate and require careful attention. They are very docile and breed well. The Himalayan is very pretty and is hardy. It breeds very well, but so very uniformly that it is quite tedious. Some of the young have black or very dark points and others have very light points. The annoyance is, that sometimes the points lighten and darken without any apparent cause. If they are kept for showing it is necessary to keep the stock always well up, as some will fall off and others improve without any apparent reason. Many persons like the

breed, and some go into raptures over it; but the uniformity of breeding, and the way of running-off for show trim has disgusted many fanciers, and there can be no mistake that the breed has already reached its zenith of popularity, and is perhaps on the descending scale. They do not require very much attention. Silver-Creams demand attention, and the many means of improving the breed often suggest much enterprise and pleasure. Hence the variety which was hardly known four years ago is now getting rapidly into favour, and is increasing in value. It often has a class at a show, and when competing in the variety class the first honours often fall to them, as the judges feel the necessity of recognising the trouble that has been bestowed on them to insure perfection. The variety is not so hardy as the Silver-Grey, but still is strong and easily kept. The very large breeds, such as the Patagonians and Belgian Hares, require large hutches but no extra accommodation, and they are very hardy. As they do not eat much more than the small ones they pay very well. They do not want any warmth or extra attention, and may be liked on that account. They are neither of them very prolific and do not pay very well for breeding. They do best for fattening, as mentioned in a previous paper.

The Dutch breed is worthy of notice. They do not want any heat, but a little uniformity will be likely to improve them. They are so very small that they do not pay for eating purposes, but as they are valued by the fancy they pay well for that. They do not require either so large or high hutches as the other varieties, and consequently are recommended for Rabbit houses of very small dimensions. They are wonderfully prolific, and the young vary a good deal; this is an advantage to speculating fanciers. The other varieties, Polish and Siberian, are neither of them much known. They are both pretty and may be liked, but neither are recommended. The first are very weak and delicate and give much trouble which is not repaid by any corresponding value, and the latter are under-rated and always considered a mongrel breed. Both require a little warmth.—G.T.A.

LOVE BIRDS

ARE natives principally of South America. The species includes many varieties, though but three are commonly offered for sale. Swindern's Love Bird is the most beautiful in plumage, and is the smallest member of the family. It is also the most delicate and difficult to be obtained. In colour the head and upper part of the body is of light green, throat black, breast greenish yellow, tail coverts deep blue; the central feathers of the tail are black, the others crimson, black, and green; bill black, legs and feet dark grey. A variety with lavender-coloured heads, from New Guinea, is sometimes found at the bird stores. These have proved to be quite hardy and easily acclimated. A green variety, natives of Java, are delicate and scarce. A second green variety differing from the first by the orange wing coverts, come to us from the West Indies. These are quite hardy. A pair kept in a conservatory during winter and an outdoor aviary through the summer have proved very attractive pets, readily responding to the call of those to whom they are accustomed, perching upon the shoulder or hand to receive some proffered tit-bit. The pair rarely are separated; where one goes the other follows. The golden-tailed Love Bird comes from Brazil. It is also quite rare. Gedney mentions a pair obtained by him at Malacca having blue tails.

The Abyssinian Love Bird is the variety commonly found in aviaries. It is hardy, feeding readily in confinement, and if given the liberty of a room shows the activity and amiability which renders the family attractive as pets. When caged they seem rather stupid, and confine the expressions of affection for each other, which have given them their name, to dressing each other's plumage and nestling close together. Like other Paraquets, they show themselves to best advantage when they have partial liberty and when familiarised by notice and caresses.

Their nesting places are in the hollows of decayed logs. The eggs are usually five in number, round, and white. Both parents share the duties of incubation and raising the young, feeding them after the manner of Pigeons, by taking the beak of the young into their own and disgorging food into it. It is best not to attempt to raise but a single brood a-year, although the hen will frequently desire to go to nest in the late summer; the care coming during the trying season of moult will injure the parents, and the young will be weakly and not likely to survive.

The entire length of the Abyssinian Love Bird rarely exceeds 6 inches; the body colour is light green with a tinge of dark blue upon the long feathers. The face of the male is of brilliant red, while in the female the shade is softer. The base of the tail is of rich turquoise; the tail feathers are of brilliant red, barred near the ends with black and tipped with green. The rich colouring and marking of the tail are only seen during the flight, the coverts hiding them when the bird is at rest.

The sex of the young of this variety cannot be determined until after the first moult. The first plumage is of dull green, and the face markings indistinct.

Gedney says, "There never was probably a prettier story told than that which assures us of the excessive grief of the Love Bird

for its lost mate, but from experience and experiment I am fully convinced that no Love Bird ever yet died of broken heart. So long as a supply of food is kept up they will suffer neither loss of appetite nor health from the death of a mate. A very amusing game goes on every evening amongst my Love Birds. They all range themselves in a row like a regiment of soldiers and crowd closely together, but the birds all object to outside places, and they accordingly fly off when forced into that position, and going to the rear they cling to the branch, where, thrusting the head between the legs of a bird in the centre of the company, the intruder lifts it bodily from its place. This continues until darkness intervenes, when the 'pivot men' resign themselves, but they frequently 'right about' to keep both sides warm from the heat of their companions." Gedney advocates white millet seed as the staple food, also soaked bread occasionally, to keep the bird in condition.—(*American Fanciers' Journal*.)

VARIETIES.

It is seldom that one can report so favourably of the agricultural look-out in North Wales as at present, and whilst farmers have the reputation of being a set of grumblers it is gratifying to write that just now there appears to be nothing to grumble about. The spring on the whole has been all that could be desired; the cereals were sown with the land in excellent order and in good time, whilst the potatoes were got in equally satisfactorily, and now mangold planting is proceeding under favourable auspices. Barley and oats are looking well; wheat has done well throughout, and looks healthy everywhere, except in some damp clayey soils. As for the cattle they have had an exceptionally good time, and the genial spring has prevented the haystacks from dwindling away into shadows, whilst it has caused the pastures to give a good bite early in the year.—(*Mark Lane Express*.)

MR. W. T. CARRINGTON, in a paper on the improvement of grass land read at one of the meetings of the Midland Farmers' Club, observed that the plan he adopted in improving inferior pastures has been to apply early in the spring a top-dressing of 4 cwt. of mineral superphosphate, 26 per cent. soluble, costing 4s. 3d. per cwt., and 1½ cwt. nitrate of soda, at a total cost of under £2 per acre. The abundant produce of grass resulting from this dressing he has consumed with cattle or sheep eating cotton cake, malt dust, or other food of high manure value, moving the troughs and feeding the animals on those parts of the fields most in need of manure. The top-dressing has in some cases been repeated, or 2 cwt. per acre of Peruvian guano substituted on those fields or portions of fields which evidently most needed help; and the system of cake-feeding upon the land continued whenever, from the low price of the extra food or the wants of the stock, it has been profitable to use it. By the judicious addition of extra foods stock will do well on coarse herbage, and may be made to graze it bare without injury to their well-doing, and the manure left by the stock is vastly superior to that of animals living on ordinary grass or fodder, producing grass of much better quality than that grown from ordinary dung.

THE following, says a correspondent in the *Irish Farmers' Gazette*, is a perfectly successful application for preserving iron and steel from rust:—Take one part finely powdered resin, three parts unrendered lard; mix together on a slab or in a mortar. This preparation should be rubbed over the iron or steel article quite thinly, but completely. It hardens on the surface into a coating easily removable by warmth, though not readily yielding to the touch. It is quite impervious to the air, and consequently preserves the object from rust for any length of time, even if placed or left in a damp situation. It is essential that the lard should be taken from the pig when killed, and not rendered, as rendered lard generally contains salt. The preparation will keep for any period, and a small quantity will sufficiently cover a large surface. He considers it a most valuable recipe, and can confidently assert from long experience that anyone using it will not be disappointed with the result.

MR. JAMES HOWARD has stated in the *Times* that seed corn can be effectually "pickled" without risk to rooks and other birds, and with saving to the farmer, by the following means:—For a sack of corn (four bushels) take half a pint of gas tar, 1 lb. of vitriol, and one gallon of hot water; pour the liquid, well mixed, over the seed with a common watering pot twelve hours before sowing. If thus treated rooks will not touch seed corn of any kind, for they, as well as other birds, appear to have a great dislike of the tar. The expense of crow-keepers is also by this plan avoided.

MR. MECHI, writing from Tiptree Hall, Essex, says, "We are certainly favoured with an exceptionally promising season for almost or quite every crop, fruit included. The sunshine of March and April, both before and after sufficient moisture, so warmed the soil and the air in contact with it that frosts lost their power, and we are at present free from those wet and severe frosts which, in early May last year, ruined our fruits and injured and delayed the general crops. Our wheats are so luxuriant that although

only sown with $4\frac{1}{2}$ pecks per acre, they may soon require flagging, and, no doubt, there will be many laid crops this year, especially where thickly sown. Barley and oats have come up quickly and fully. Peas look admirably, and have been already twice horse-hoed. Mangolds are up. I never saw clover more luxuriant, and our tares are already fit for an early cutting. Surely if the weather continues so favourable harvest is likely to be early. Land owners and land agents will now cease to be melancholy, and let us hope and believe that trade generally will also revive—if we have peace. When I look at the produce of this farm I feel what a vast gap might be profitably filled up in home-food production."—(*Farmers' Gazette*.)

THE following, says S. D. McLean in "American Bee Journal," is a good method for dividing bees, and one that is both practical and easily performed by the experienced. After providing an extra hive with empty frames, or better, frames filled with comb, proceed to open the hive to be divided, and after subduing the bees with smoke or otherwise, lift out the brood combs with all adhering bees until two-thirds of all the brood is removed, placing the same in the new hive and being careful not to remove the queen. Fill all unoccupied space in both hives with comb frames. Locate the new hive some distance from the old. All the old bees will return to the parent hive, but enough young bees will remain to care for the brood. A fertile queen may be given the new colony after forty-eight hours, or about sunset on the second day, by quietly setting her on one of the brood combs. The bees being all young will accept her and the work is done. We introduced many queens to new colonies last season, as here given, without the loss of a single queen. The new colony will not work much for a time, but is generally equal if not superior to the parent stock in a few days.

A CORRESPONDENT who has been much troubled with wireworms records the following experience:—I tried many of the usual remedies but with small success. At last I adopted a plan that has invariably proved quite successful. In 1876 I thought it desirable to break up a field, fourteen acres in extent, of partly light bog and partly sandy and gravelly hills. It was covered with long old grass that cattle would not eat, and just the kind of place for the wireworm to work. At the time of sowing the oats I applied to nine acres a dressing of 8 cwt. common salt and 8 cwt. dissolved bones per English acre. The remainder of the field, which was the best of it, got no manure. The manured portion escaped the wireworm and produced a good crop considering the soil. The unmanured portion was so much cut up that it was not worth harvesting. Last year I had a field of very old lea, part bog and part gravel; to eleven acres of it I applied, in addition to the bone manure and salt above mentioned, 1 cwt. of nitrate of soda per statute acre. It produced a remarkably good crop; some of it too luxuriant, though the soil was very poor and thin. One acre remained unmanured, and the wireworm cut it up very much indeed. I am quite satisfied that the dressing has checked the wireworm in my case, and I see no reason why it should not do so in other cases as well. I have not tried salt alone, but probably on rich or well-manured land it would do equally well without the bone manure. But as the expense altogether is only about 2s. per acre, there will be ample return in corn and straw to repay that amount and leave a handsome profit besides.

THE crop reports received recently from all parts of the State of California are of the most favourable character. With few exceptions there is a prospect of an abundant harvest in all quarters. The southern portion of the State and the San Joaquin Valley, in which the crops failed last year, promise equally well with the northern valleys. In some localities there is complaint that the early-sown grain has grown so rank as to lodge, but this has not occurred to any material extent. The exceptions above referred to are the low bottoms in the Sacramento Valley which were drowned out by the February floods, and the Tule Islands in the delta of the Sacramento River.

WINTERING BEES—EKEING BAR-FRAME HIVES.

SOME weeks since Mr. Pettigrew wished to elicit information from different parts of the country relative to the wintering of bees during the past season. In this locality many hives have perished, but the mortality has in almost every instance which has come under my notice been occasioned by famine. The consumption of stores has been unusually great in consequence of the mildness of the winter, but where the bees have been properly supplied with food the hives are populous and likely to do well if we have a favourable season for honey gathering. Out of four stocks in my own garden two are very strong and the others fairly so. One of the strong colonies wintered in two Stewarton boxes and the other in a wooden Woodbury frame hive. Both of these were pretty well crowded with bees before the end of April, and I was able to start a nucleus box upon the 1st of May and a second upon the 18th, obtaining all the bees and brood from the Woodbury hive only. A queen is now at liberty (May 15th) in each of these young colonies.

Mr. Pettigrew is in error when he states, "The bar-frame hive is not made or meant for enlargement by eking or additions." I have for many years used Woodbury frame hives for storing, and have given additional room, below for breeding and above for honey storing. The ekes or nadirs employed are of the simplest construction—simple square frames or rims, 3 or 4 inches in depth and of the same size as the hive. The first of these ekes is furnished with ten moveable bars to which the bees attach their combs, so that it can at any time be removed with the greatest facility without interfering with the stock hive. If additional breeding room is still needed a simple square rim without bars is inserted below the first eke, and this process can be carried on *in extenso*. Stewarton boxes have been greatly improved by altering the width of the bars and varying the distances in the breeding compartments, and above all, for facility of manipulation, by the introduction of four frames in the centre of the stock boxes, which renders it easy to remove all the combs when necessary, enabling the bee-master to excise royal cells or strengthen weak colonies by the addition of ripe brood combs with the greatest facility.—J. E. BRISCOE, *Albrighton*.

OUR LETTER BOX.

HENS DISEASED (*J. S. Cairnie*).—They have ulcerated bowels. There is no cure. Have an entirely fresh stock.

CAGED THRUSH (*Turdus musculus*).—Set at liberty at this time of the year it would be able to provide for itself.

REMARKS.

15th.—Wet morning; fine and bright after 9.30, very high wind between noon and 2 P.M.; wet night.
16th.—Fair day but dull, intervals of sunshine, shower at 4 P.M., high wind and showers in evening.
17th.—Fine sunny day; windy, dull, and heavy in evening.
18th.—Thunderstorm until A.M., very near from 5.42 to 6.30 A.M.; fine bright day with high wind.
19th.—Showery very windy day; fine evening.
20th.—Cloudy morning, slight rain, heavy showers during the day; cold in evening.
21st.—Fine bright morning, cooler, thunder and lightning at 2.40 P.M. and Temperature very similar to previous week, but very windy, and at times thundery. The night of 20th–21st very cold, almost frosty.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 23.

ALL classes of fruits and vegetables are now plentiful with us, and with trade very quiet are realising very low prices.

PREPARING STRAWBERRY PLANTS FOR PLANTING.

N making young plantations of Strawberries it is very important for the perfect and rapid success of the undertaking that the very best young plants obtainable are used. In many instances there is not sufficient attention paid to this, as evidence of it is found in the inferior plants, or plants of any description, that are so often planted without any selection or preparation. It is a very common practice to allow the runners to root into the ground around the old plants, and when planting time comes they are drawn up from there and planted in their permanent quarters. As a rule, plants treated in that manner grow little or nothing for months after they are planted, and it takes them all the following season to grow into fruiting state; consequently they are two or occasionally three years old before they bear a full crop. This is a serious waste of time, for there is no reason why the plants should not bear as heavy a crop the first year as the third.

We have some long rows of young plants now with four and five dozen berries set on each, and the plants were not formed into runners at this time last year. About the end of last June when the runners had produced four and five leaves each, and just when they were beginning to emit little roots where they were resting on the ground, they were taken in hand to prepare for planting. Some hundreds of 3-inch pots were filled with a rich mixture of half-decayed manure and half loam. All the best of the runners were selected, and each one was placed on the surface of the soil in the flower pot with the little roots in the centre. A small stone was laid on each runner close to the neck of the plant to steady it in the pot until the roots could affix it firmly. The pots were watered as required, the soil never being allowed to dry, and the pots were quickly filled with roots. The young plants were then quite able to do without any support from the parent plants, and the runners were cut close to the edge of the pot. The plants were then placed close together along the edge of a walk fully exposed to the sun. Here they soon became quite hardy, and about the middle of August they were planted where they are now bearing a crop. When planted every one of them had a mat of roots, which took to the open soil at once, and by the end of September they were quite established in the ground. No doubt it is owing to this that they are doing so well now; and although layering them into pots is a little trouble at first, it is amply repaid afterwards. As the time for selecting Strawberry runners is again close at hand I certainly advise all who desire strong plants and early crops to adopt this plan of raising their young plants.—A KITCHEN GARDENER.

CHRYSANTHEMUMS—SUMMER-STRUCK PLANTS.

As a gardener my time and attention have to be divided amongst various genera of plants, the Chrysanthemum being one of these as a plant useful for cutting and decorative

purposes; apart from which it is a plant most extensively grown for exhibition, more particularly around London, where numerous societies have sprung up of late years, and are still increasing, the express object of them being to encourage the growth of the Chrysanthemum. Judging from the beauty and excellence of the specimens exhibited no doubt can exist that these societies have produced the desired effect.

Of exhibition plants, however, it is not my present intention to speak, but to point out how a number of useful plants may be obtained for decorating rooms and conservatories from cuttings taken early in June. Much finer and larger blooms may of course be had by taking cuttings when the old plants are in bloom in November and growing on throughout the spring; but smaller plants, even at the expense of not having the flowers so fine, are very useful, for being in smaller pots they may be moved about and changed more easily, and are more useful for small stages and vases for indoor decoration. I am aware that at this time of year Chrysanthemum lore is not very popular, nevertheless if good results are wanted they now need as much attention as at any time.

The method of procuring a supply, as just stated, is to take the young tops from the old plants, as many as may be required, the first or second week in June, and insert them immediately in sandy soil in 5-inch pots, place them in a frame on a hotbed, and to be kept sprinkled and shaded for a few days till rooted—the main point for their rooting quickly is not to let the cuttings flag—then to be gradually hardened off in a cold frame for a week or so. When the roots reach the sides of the pots they may be divided and potted into 3-inch pots, using a compost of turfy loam and a little well-rotted manure, with enough sand to keep it porous. Place them back in the frame, and keep close a few days till established, when they may have all the air and showers possible; and when rooted through repot them into their blooming pots, which may be 5, 6, 7, or 8-inch, according to their strength. The large-flowering varieties will do better in the latter size, an intermediate shift not being at all necessary. I have before now divided the rooted plants from the cutting pots, and put them in their blooming pots at once with very good results. As to stopping, as it is termed, or pinching out the extreme point of the young plant to induce a bushy habit, for the large-flowering kinds once will be sufficient; but the Pompons, especially the early kinds, as the Cedo Nullis, may be stopped till the middle of August.

The chief attention throughout the summer will be to give them plenty of water as they require it, with clear weak liquid manure twice a week, stirring the surface with a stick now and then—a practice that is very beneficial for most plants in pots, as well as vegetables in the open ground. In speaking of using liquid manure I have used the word "clear," and it is important, for if used in a thick state the sediment forms a coating over the surface of the pots, excluding air and rendering the plants less vigorous. A south aspect, the pots plunged halfway to their rims in a bed of coal ashes, is a good position for them, giving them enough room so that air may circulate freely about them

and induce short and firm growth, for without it good blooms must not be expected. A sprinkling overhead in the evenings of fine days promotes health and a free growth. In October a light airy greenhouse is the most suitable place for them, syringing them once a day till the flowers show their colour, when they may be transferred to where wanted. At this season, too, they require an abundance of water. By the above treatment I have had plants from a foot to 18 inches in height, bushy, and with foliage from top to bottom, and with good heads of bloom.

A method practised by some cultivators of the Chrysanthemum is to put the young plants in the open ground, attending them as to stopping and watering as for those in pots, and when the buds appear or begin to open to take the plants up and pot them, by carefully cutting the roots, and allowing them to produce fibres again. Now I have tried this plan, and have seen many others do it, but from the appearance of the plants so grown after they are lifted and showing their colour I have noticed that when the plants should be at their best the greater part of the foliage has turned yellow very prematurely, and when stripped of it they have a painfully bare appearance, so that it is a plan I will neither adopt myself nor recommend to others. Much larger plants no doubt may be obtained, but as the roots ramify and spread out in all directions the cutting them back to enable their being put into pots I am convinced does them an injury—an injury detrimental to the bloom and foliage too.

Generally speaking very few gardeners have the opportunity or even the desire of testing a very large number of sorts, but good growers generally manage to acquire those most suitable for their purpose. This applies more particularly to those who grow for exhibition, but the undermentioned kinds are good and useful either for exhibiting or not:—Large-flowering: Mrs. Rundle, Mrs. Dixon, George Glenny, Jardin des Plantes, Empress of India, Aurea multiflora, Antonelli, General Bainbrigge, Lady Harding, Alfred Salter, Fleur de Marie, Little Harry, Queen of England, Nil Desperandum, Prince of Wales, Princess of Wales, Prince Alfred, Mr. Brunlees, Robert James, St. Patrick, La Belle Blonde, Mrs. Haliburton, Julie Lagravère, Golden Eagle, Venus, and Faust. Amongst Pompons the following are as good as any:—Cedo Nulli, Lilac and Golden Cedo Nulli, Middle Marthe, Bob, Brilliant, Aigle d'Or, Antonius, Mr. Astie, Duruflet, Hélène, Astrea, Rose Marguerite, Madame Montells, Général Canrobert, St. Thais, Mrs. Hutt, White Trevenna, Rose Trevenna, Calliope, Mrs. Wyness, Marie Stuart, and Marabout. There are many others all more or less good, but all the above-named are well-proved kinds. The Japanese kinds are curious and ornamental, and a few kinds are worth having in every collection. Your able correspondent Mr. Moorman called particular attention of them to your readers some time ago.—A. HARDING, *Orton Hall*.

ROSE PROSPECTS.

As there has been presented to me an unusually good and delightful opportunity (the inevitable umbrella as the only drawback being every day called into requisition) of visiting several gardens of our leading rosarians, both amateurs and nurserymen, in the west midland district from Hereford even to Torquay, I am happy to state that the prospects of the fast-approaching Rose season, in spite of long drenching rains and successively sunless days, never were, in my somewhat long experience, more hopeful. Roses everywhere that I have seen are breaking healthily and vigorously, and only require that anxious supervision and constant attention which the queen of flowers demands from her loyal subjects as a just tribute to her incomparable merits and imperial position. Nature's prodigality is man's opportunity, and as well might one expect a crèche or baby farm to produce the dimpled cherubs of the maternal well-appointed nursery as the neglected half-starved occupants of too many *soi-disant* roseries (it matters not whether of peer or peasant) the splendid exhibits of a Baker or Jowitt, a Cranston or George Paul.

A lady of title wrote to me a short time ago that she could not see her way to patronise a certain Rose show because she felt her inferiority to nurserymen, and strongly objected to her Rose trees or bushes being cut down to a few single shoots. Now, I have before in the "Rose Journal" expressed an opinion that misapprehension about the very rudiments of Rose lore gives to some extent a clue to the mysterious reason of the failure of Rose shows in a financial aspect, and such objections as these appear to supply a case in point; for I hold no

amateur need necessarily yield the pride of place to a nurseryman in an open class, certainly not in small exhibits, for Teas we often find taken by amateurs; while the fact of the clearly defined line between the two divisions of nurserymen and amateurs, preventing all possible fear of mistake, undue rivalry, and jealousy, has always seemed to me a most praiseworthy feature in Rose schedules, as avoiding a rock of offence on which many a general horticultural society has split. With regard to the other objection alluded to by my correspondent, I need only say that as to the advisability of cutting down a Rose tree or bush to a few shoots more or less, if done discreetly—whether it be merely with a view to garden decoration and general effect, or to the health and greater longevity of the plant, or for exhibition purposes—there could practically be but one opinion.

Asking pardon for this digression I would call especial attention at the growing season to the necessity of prompt and severe disbudding—a process if anything more important than late pruning, helping as it does not only to strengthen the roots and evenly to distribute and concentrate the flow of sap, but by removing weak, injured, and crowded shoots to allow a free circulation of air throughout the plant, and especially that of light, which is the most dreaded enemy of all natural foes—grubs, aphides, mildew, &c.—as well as moral. Of equal value, and about the same time as disbudding, mulching should (if not already) be done. I noticed lately in the perfectly attended to and highly cultivated Rose garden of my friend Mr. Baker of Heavitree, that it is his custom to cover over his mulching (pig-dung manure for choice) with a fairly thick layer of soil taken off a spade's breadth from between the rows of his Roses. This is a simple but excellent plan, for two reasons—it prevents undue evaporation, and removes the common objection of unsightliness. Another "wrinkle" I may mention here with profit, I believe, to some of your readers is this—Mr. Baker never waters his Roses with any "goodies" in the shape of liquid manure of any kind or degree until the flower buds are in the course of early development. This is a very important distinction; and especially in a wet season like last year (I speak very feelingly on this point) goes far to make the whole difference between failure and success, premature application leading to coarse-growing non-blooming shoots.

It was a very gratifying sight to notice within a few days how remarkably well likewise the Rose garden of my near neighbour and friend Mr. Jowitt, the winner of the champion cup last year, looked. So marvellously and evenly bright indeed do the prospects of these two great rosarians appear to me that the public will look with all the keener interest to their meeting, and if there should be a "dark horse" (as one hears mysteriously), the more the merrier at the National, at the Crystal Palace, and the West of England Rose Shows, where as holders they will again contend for Messrs. Cranston's two grand silver cups.

I have had within the last few days several opportunities of seeing Messrs. Cranston & Co.'s nurseries, and nothing can look more promising than the prospect of their Roses, whether their vast extent (the largest in the United or any kingdom) or the healthiness of the plants themselves be considered. I may mention *en passant* that the large Tea and Noisette house of this firm has been during the spring a thing of beauty to be seen and enjoyed, but spoilt by description. Fancy thousands of thousands of the most charming of all Roses of every conceivable tint, and shape, and fragrance, in the most perfect state of health and luxuriance—standard and half-standard, bush and climbing Roses everywhere meeting the delighted gaze—and just a slight idea can be formed of its unsurpassed loveliness.

Yesterday I passed a pleasant hour at Mr. Curtis's nursery at Torquay, and having been there several times before I was much struck by the extent to which he had increased the hem of his border. There have been, I am told, some six or seven acres added to these already fine nurseries. I was especially struck with a piece of twenty thousand H.P.'s on standard Briars, which I have no hesitation in describing as the finest I have ever seen. Mr. Curtis's Roses possess a virtue we of Herefordshire would much like to possess, I mean their early maturity, and for this reason if for no other (especially if this wet sunless weather lasts), I venture to predict the Torquay nurseries will be favourably heard of at our early exhibitions. I saw in one of Mr. Curtis's houses a Tea Rose I think most highly of, raised by Madame Ducher, it is named Madame Welch, and said to be after *Devoniensis* impregnated by

Souvenir d'un Ami; I failed, however, to recognise the parentage. It is a bold, grand-petalled flower of a fine growthy habit and very distinct, and will be appreciated when known.—THE HEREFORDSHIRE INCUMBENT.

ROYAL HORTICULTURAL SOCIETY.

GREAT SUMMER SHOW.

MAY 28TH, 29TH, 30TH, AND 31ST.

EVER since the great and spontaneous display made by the leading nurserymen on July 21st, 1875, the meetings and exhibitions of the Society have been both for extent and quality one continued series of successes. The Show referred to was of an honorary character—a great horticultural rejoicing; but the one following of June 7th and 8th, 1876, was competitive. This was succeeded by the memorable gathering of the 2nd of May of last year, when Her Majesty graciously recognised the work of the Society, and visited such a display as was never seen before in any country—namely, the wonderful productions of the growers of plants for Covent Garden Market and the embellishment of metropolitan homes. This signal success was followed six weeks afterwards by a success if possible still greater, when, on June 19th, H.R.H. the Prince of Wales met with such a loyal reception, and when the gentle and popular Princess distributed the prizes that were awarded at the previous Exhibition. Between those great Exhibitions many extensive and valuable displays have been arranged at the periodical meetings of the Society by the principal nurserymen and a few spirited amateurs, and now comes the event of the year so far as regards London, and the Show is greater, brighter, and better than ever; in fact, it is without doubt the most extensive, varied, and rich Exhibition that has been seen in London since the Great International display of 1866. Being held earlier in the season than the shows above referred to, flowering plants preponderate where before foliage prevailed, and flowers, no doubt, more than foliage command the admiration of the British public. Besides the flowers to attract was that other great attraction which is irresistible to a loyal people—the presence of Royalty, the heirs to the thrones of the two most powerful nations of the world. Nothing could have been more gratifying to a large and important section of the community than the announcement that their Royal and Imperial Highnesses the Prince and Princess of Wales and the Crown Prince and Princess of Germany intended visiting the Exhibition. As soon as that fact became known it was certain that horticulturists would put forth their strength and render the Show worthy of such distinguished and highly appreciated patronage. So great are the advantages of horticulture, so powerfully does it contribute to the enjoyments, even the necessities of life, so numerous are the workers engaged in the craft, that it is no wonder it should receive a share of that Royal recognition that gives such a great impetus to whatever it is vouchsafed. The Royal party arrived about twelve o'clock. The Crown Prince and Crown Princess with their suite came punctually at twelve, attended by Count Seckendorff, Major von Panwitz, and Viscount Bridport, and were received by Lord Aberdare (the President), Mr. G. T. Clarke, V.P., Mr. Henry Webb (Treasurer), Mr. Philip Miles, Major Mason, Mr. Haughton, Mr. Talbot Dillwyn Llewellyn, and Dr. Denny; and the Princess of Wales arrived about five minutes later, accompanied by her brother Prince Waldemar of Denmark, and the Princess Victoria of Wales, attended by Lady Suffolk and Col. Teesdale. They were received by Lord Alfred S. Churchill, V.P., and Dr. Hogg, Secretary.

The Exhibition now arranged, and which continues until Friday night, is emphatically a competitive one, the aggregate value of the prizes offered exceeding those provided at any other show hitherto held during the present season. Of the total amount of £1000 we find £39 apportioned to stove and greenhouse plants, £114 to Orchids, £30 to new and rare plants, besides the valuable cups provided by Mr. Bull; £68 for Azaleas; £85 for Roses; £118 for Ferns, Palms, and fine-foliaged plants; £68 for Pelargoniums, £40 for fruits, and £12 for vegetables; and in addition Sir Trevor Lawrence's liberal prize of £10 for the best specimen Orchid, and Mr. Gallop's prizes of £10, £7, and £5 for twelve plants of Miles' "Spiral" Mignonette. Such are the awards provided, let us now see by whom and in what manner they are won. We may first, however, briefly glance at the general character and effect of the Exhibition.

As on previous occasions the most important collections are arranged in the large marquee. On descending the steps from the Council room entrance to the gardens we arrive immediately at a tent 100 yards in length containing new plants, Orchids, Mignonette, Gloxinias, Cactuses, collections of cut flowers, fruit, and vegetables—a foretaste and an appetising one of the feast to follow. From this tent a canvas-covered way 100 yards long conducts to the great marquee, but before arriving at which we find

another extensive tent filled with succulents, Pelargoniums, and a splendid miscellaneous collection of plants from some of the leading nurserymen.

On arriving at the large marquee a cool, refreshing, and exceedingly pleasing arrangement of rocks, plants, and trickling water by Messrs. Dick Radclyffe & Co. first arrests notice. On the right and left are Ericas, and beyond them grand collections of Ferns. We now reach the hollow centre of the tent, and whichever way we turn the scene is one of great splendour. At our feet is the central circular group of Messrs. Veitch, which is an arrangement of extraordinary richness. This fine central group, which had the post of honour, has as a central plant a splendid specimen of the valuable Palm *Kentia Fosteriana*, surrounded by Palms of more slender growth, and associated with the stately *Anthurium Brownii*, *Veitchii*, and the beautiful *Waroqueanum*. Bright-foliaged *Dracenas* and choice *Crotons* were in the group, and very effective is *Crinum Verschaffeltianum*. The brilliant colour is imparted by a profusion of spathes of *Anthurium Scherzerianum*, *Oncidium crispum*, and the very fine *Hemantus Kalbreyeri*. Extremely bright also are the plants of *Dendrobium suavisimum* and *Oncidium concolor*, which are both remarkably good, as also is another bright-flowering plant of *Rhododendron Crown Princess* of Germany, orange buff with chocolate stamens. Softer colours are represented by many splendid Orchids—*Odonoglossum vexillarium*, *Pescatorei*, *Alexandrae*, *citrosium*, *cirrhosum* and *Rozii*; gorgeous *Cattleyas*—*Mossiae* and *Mendeli* by dozens, and *Lælia purpurata*; a fringe of *Gloxinias*, tuberous *Begonias*, and Ferns imparted a charming finish to a valuable group. *Dendrobiums* and *Nepenthes* elevated above the other flowers impart grace and freedom to the arrangement. *Utricularia montana* is extremely fine and very beautiful by its profusion of white flowers, and beauty of another kind was represented by the fine *Tillandsia major zebrina*.

At the extreme end of the tent is what is unquestionably the most imposing feature of the Show, such a sight that has certainly never been seen before and can hardly be expected to be seen again—namely, the magnificent bank of Roses in pots from Mr. Turner of Slough. The veteran cultivator has surpassed himself, and has nobly crowned all his past efforts, great as those are admitted to be. The semicircular mound is occupied by the nine giants, which even without the historical Paul Perras, the hero of quite half a hundred fights, is one of the finest groups ever set up. Spreading from the central are two wings occupied by about eighty specimens in 10-inch pots, the whole, both as regards foliage and blooms, are as near perfection as any Roses have ever been seen. The group, backed by towering Tree Ferns, cannot in any adequate manner be described. These Roses are the wonder of all observers—no one knows how they have been grown so well, but it is the fact that it required sixteen horses to convey them to the Show. Besides receiving the first prizes for nine and twenty plants Mr. Turner was deservedly awarded a gold medal for this magnificent collection. At the opposite end are the nine splendid specimens from Messrs. Paul & Son, backed by a collection of Palms.

Near to Mr. Turner's Roses the largest of the side mounds is wholly occupied with plants from the establishment of Mr. Bull. The centre comprising large and valuable Palms, Tree Ferns, and ornamental-foliage plants margined with flowering plants of great beauty and rarity. Most charming amongst these is a bank of Orchids, consisting of groups of *Odonoglossum vexillarium*, *O. Pescatorei*, *O. Alexandrae*, &c., nestling in a carpet of *Gauze Ferns*—a truly splendid finish to a grand group, many plants in which are noticeable. *Anthurium Scherzerianum album* with ten spathes must not be passed over, nor the noble Palm *Pritchardia grandis*, the only one in England if not in Europe. Under the shade of this plant a group of the strikingly marbled *Dracæna Goldiana* shows to great advantage. *Phyllotenum Lindenii*, very fine, *Hemantus cinnabarinus*, *Hoffmannia Ghiesbreghtiana variegata*, *Pelargonium Prince of Wales*, very bright, the remarkable *Ataocia cristata* with its brown-black flowers and long tails, *Coffea liberica*, and grand *Cycads*, all arrest attention. It is a great group of great value.

The other mounds in the centre of the tent are occupied—one with Azaleas, Palms, and fine-foliaged plants, the other with fine-foliaged plants and a group of decorative plants from Mr. Aldous, and the third by Azaleas again, and such an artistic example of bold and tasteful arrangement of plants by Mr. Wills as even that renowned decorator has not previously achieved. It is arranged in a series of rugged terraces, the base being carpeted with *Lycopodiums*, out of which spring in pleasing informality choice Orchids, *Gloxinias*, and *Amaryllises*. Half way up the bank is a mossy dell, and beyond a mound closely covered with feathery *Spireas* (*Hoteias*); and besides the low plants noticed, and what constitute the charm of the group, are elegant tall Palms, *Dracænas*, and other fine-foliaged plants dotted here and there, representing tropical trees growing out of a carpet of moss and flowers. Mr. Wills' and Mr. Aldous' group were in competition in Class 18, and the prizes were awarded in the order of their names. The sides of the tent are occupied by other competing collections. The second-prize group has an extremely

chaste appearance, owing in a great measure to its beautiful fringe of *Caladium argyrites*.

We now pass to the several classes.

STOVE AND GREENHOUSE PLANTS.—In the open class for twelve plants in flower, first honours go to Mr. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, for a really fine group, consisting of two grand *Azaleas*, *Ericas* *Cavendishiana* and *ventricosa* *magnifica*, *Clerodendron* *Balfourianum*, *Bougainvillea* *glabra*, *Pimelea* *decussata*, *Allamanda* *grandiflora*, *Dracophyllum* *gracile*, a magnificent *Anthurium* *Scherzerianum*, *Aphelexis* *macrantha*, and *Statice* *profusa*. Messrs. Jackson & Sons, Kingston, are placed second. Extremely fine in this collection are *Erica* *eximea* *superba*, a dense globe of flowers $4\frac{1}{2}$ feet in diameter; *Aphelexis* *macrantha* *purpurea*, and *Dracophyllum* *gracile*. The third prize is awarded to Mr. Peed, Roupell Park Nurseries, for medium-sized symmetrical plants about 8 feet in diameter and in good condition.

In the nurserymen's class for eight plants Messrs. Jackson and Sons have the premier position with a very fresh and bright group, the plants averaging $3\frac{1}{2}$ feet in diameter; they comprise *Ericas* *affinis* and *Candolleana*, *Statice* *profusa*, *Hedera* *tulipifera*, an *Aphelexis*, *Azalea*, and *Anthurium*. Mr. B. S. Williams secures the second place. The white *Erica* *magnifica* in this collection is a splendid plant, and very good are the *Clerodendron* and *Aphelexis*. In the corresponding class for amateurs the first prize is awarded to Mr. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, for an excellent collection. The most striking plants are *Azalea* *Duchesse* *Adelaide* *de* *Nassau* in magnificent bloom, *A. Iveryana*, *Erica* *Cavendishiana*, *Clerodendron* *Balfourianum*, *Pimelea* *Hendersoni*. An *Anthurium*, *Aphelexis*, and *Hedera* *completa* the group. Second honours go to Mr. Tudgey, who stages large and fine plants, but some of them not quite fresh and well bloomed. The most noticeable and fine are *Erica* *ventricosa* *grandiflora*, a globe 3 feet in diameter, and another *Erica* 4 feet in diameter. Mr. Wheeler, St. John's Wood, Regent's Park, has the third prize.

AZALEAS.—In the nurserymen's class for eight plants, distinct, Mr. Turner, Slough, is awarded the chief prize for his informally trained specimens, in which healthy foliage is seen amidst fine flowers. *Souvenir* *de* *Prince* *Albert*, 5 feet high, is a splendid plant. Messrs. Jackson follow with small bushes 2 to 3 feet in diameter. In the corresponding amateurs' class for the same number of specimens Mr. Child, Garbrand Hall, secures the premier place with undoubtedly the finest *Azaleas* in the Exhibition—pyramids ranging from 4 to 6 feet high, densely covered with fine flowers. The varieties are *Juliana*, soft scarlet; *Model*, rose; *Goethe*, white; *Chelsoni*, orange scarlet; *Charles* *Encke*, flesh and salmon; *Grand* *Crimson*, really grand; *Reine* *des* *Pays* *Bas*, lilac; and *Tricolor*, white faintly flaked rose and scarlet. Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, is awarded the third prize. In the open class for fifteen plants in pots not exceeding 12 inches in diameter Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham Hill, is awarded the place of honour with well-bloomed specimens of dwarfs and pyramids. *Callina*, deep rose; *Souvenir* *de* *Prince* *Albert*, *Bernard* *Andreas*, and *Mons.* *Thibaut* are the most effective varieties. Mr. Turner was placed second for plants rather smaller, but in good variety and well bloomed.

ERICAS.—In the nurserymen's class of eight plants Messrs. Jackson & Son had the premier position. Some of the plants were rather loose, but others were good and had fine flowers—notably *E. depressa*, *E. ampullacea* *obovata*, *E. Candolleana*, and plants of the *ventricosa* type. In the corresponding class for amateurs Mr. Tudgey is awarded the first position with some excellently bloomed specimens about 3 feet in diameter; very fine are *E. depressa*, *ventricosa* *coccinea* *minor*, *Cavendishiana*, *tricolor* *speciosa*, and *tricolor* *Wilsoni*. Mr. Weston, gardener to D. Martineau, Esq., is placed second; Mr. Wheeler is awarded the third prize.

ORCHIDS.—The display of these is very extensive, occupying almost the entire length of a tent nearly 100 yards long, and the collections are generally excellent. In the amateurs' class for fifteen plants, distinct, Mr. Rutland, gardener to the Duke of Richmond, Goodwood, wins the first place with a collection containing some magnificent plants. *Cattleya* *Mossiae* is very fine. *C. Mossiae* *magnifica* is 3 feet across and has fifty gorgeous flowers. *Vanda* *suavis* has four grand spikes, and *V. suavis* *tricolor* three. *Cypripedium* *caudatum* has twelve remarkable flowers. *Odontoglossum* *Alexandrae* has five strong spikes; and singular rather than beautiful in this fine group are *Epidendrum* *ciliare* and *Cypripedium* *Hookeri*. Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, secures the second prize with a fresh and good collection. *Dendrobium* *formosum* *giganteum*, *D. Dalhousianum*, *D. Bensoniae*, and *D. thyrsiflorum* are excellently represented. *Odontoglossum* *Alexandrae* is very richly coloured, as also is *Masdevallia* *Harryana* with twelve fine flowers. *Cattleya* *Mossiae* *superba*, *Cypripedium* *spectabile*, *C. villosum*, and *Odontoglossum* *citrosium* are very good in this collection.

In the corresponding nurserymen's class for the same number of plants Mr. Williams is in his old position—first, with a rich and

splendid group composed of *Cypripedium* *niveum* with about fifty flowers; *C. caudatum*, twelve grand blooms; and *C. barbatum* *superbum*; *Cattleya* *lobata* *Mendeli* and *C. Mossiae*, *Lælia* *purpurata*, *Dendrobium* *Jamesianum*, *Masdevallia* *Harryana*, *Vanda* *insignis*, *Dendrobium* *nobile*, *Odontoglossum* *Alexandrae*, *Calanthe* *veratrifolia*, and a grand plant of *Cypripedium* *villosum* about 3 feet in diameter. Messrs. Jackson & Sons have the second prize with an excellent collection. *Saccolabium* *retusum* and *Lycaste* *aromatica* in this group are greatly admired. The nurserymen have also a class provided for six plants. Mr. Williams again wins the chief place with six splendid examples of *Cattleya* *Mendeli* with eight grand flowers, *Odontoglossum* *vexillarium* *fourteen*, *Cypripedium* *caudatum* *twenty*, *C. barbatum* *superbum* *fifty*, *Dendrobium* *thyrsiflorum* with thirteen fine racemes, and *Masdevallia* *Iveryana* with eighteen flowers. Messrs. Jackson & Sons are second with excellent examples of *Dendrobium* *thyrsiflorum*, *Odontoglossum* *Alexandrae*, *Vanda* *suavis*, *Phalenopsis* *amabilis*, *Dendrobium* *nobile* *cerulescens*, and *Cattleya* *Mossiae* with sixteen flowers. Mr. Henry James, Castle Nursery, Lower Norwood, is third with *Dendrobium* *densiflorum*, *Cattleya* *Mendeli*, *Oncidium* *crispum*, *O. Marshallianum* *fine*, *O. Alexandrae*, and *O. cirrhosum* *very* *good*.

In the amateurs' class for ten Orchids Mrs. Torr, Garbrand Hall, wins the first prize with splendid examples of *Aërides* *Fieldingii*, *Oncidium* *Devonianum* and *O. ampliatum* *majus*, *Brassia* *maculata* *superba*, *Dendrobium* *nobile*, *Odontoglossum* *crispum*, *Cypripedium* *crispum*, *Dendrobium* *crystallinum*, *Lælia* *purpurata* *superba*, and *Cypripedium* *niveum* and *barbatum* *superbum*.

SPECIMEN ORCHID.—The prize of £10 offered by the great patron of Orchids, Sir Trevor Lawrence, Bart., M.P., for the best plant not made up, is won by Mr. Perry, gardener to J. W. Miles, Esq., Shirehampton, Bristol, with a grand specimen of *Lælia* *purpurata* with nine spikes and thirty-four magnificent flowers. Splendid also in this class is *Dendrobium* *thyrsiflorum* from Mr. Tutecher, gardener to P. S. Miles, Esq., King's Weston, Bristol. Mr. Child also exhibits *Cypripedium* *Stonei* *very* *fine*.

NEW PLANTS.—In the open class for nine plants not in commerce, in or out of flower, Mr. Bull is placed first with a striking collection, consisting of *Dieffenbachia* *reginae*, prevailing colour a greenish cream, blotched green, very effective; *Anthurium* *insigne*, deeply trilobed foliage, striking; *Davallia* *fijiensis*, very elegant; *Philodendron* *Carderi*, large velvety foliage veined with green; *Croton* *formosus*, foliage like *C. Weismannii*, but intensely coloured with crimson; *Dieffenbachia* *Leopoldi*, fine ovate foliage 10 inches long by 6 wide, rich green, with a midrib of pure white; *Aralia* *concinna*, rich dark green, very elegant; *Dipteris* *Horsfieldii*, and *Zamia* *princeps*, certainly one of the most elegant of the Cycads. Mr. Williams is second with *Encephalartos* *latifrons*, one of the grandest Cycads we have seen, it is of stately growth, and has rich green foliage; *Croton* *Crown* *Prince*, highly attractive and very promising; *Aralia* *nobilis*; *A. spectabilis*, very elegant; *Croton* *Williamsii*, a bold *Croton* and richly coloured; *Adiantum* *Williamsii*, a beautiful Fern of the *A. cuneatum* type, but abundantly distinct; *Wallichia* *zebrina*; *Alsophila* *Macleayi*, grand bright green fronds; and *Dracaena* *Mastersii*, dark bronze, richly coloured with bright crimson, fine. In the class for twelve plants sent out in 1875, 1876, and 1877, Mr. Bull again wins the premier position with plants not only new and rare, but fine and in superior condition. The collection consists of *Dieffenbachia* *maculosa*, bright and telling; *Bowenia* *spectabilis* *serrulata*; *Philodendron* *gloriosum*, large cordate leaves, satiny green, with ivory white midribs; *Pavonia* *Wiotii*, *Croton* *Disraeli*, *Cibotium* *Menziesii*, *Anthurium* *Veitchii*, *Anthurium* *Dechardii* with four fine spathes, interior pure white, exterior green; *Cataglyphis* *Hopeli*, a fine Cycad; *Lomaria* *discolor* *bipinnatifida*, a splendid Australian Fern; *Dendrobium* *suavissimum*, bright yellow, maroon lip, and the finest plant of *Dracaena* *Goldiana* that has yet been exhibited. Mr. B. S. Williams follows with a very fine group, comprising *Maranta* *Massangeana*, *Croton* *Andreanum*, *Kentia* *Mooreana*, *Adiantum* *princeps*, *Dracaena* *Imperator*, *Brahea* *filamentosa*, *Croton* *Queen* *Victoria*, *Areca* *flava*, *Platyceium* *Willinkii*, *Croton* *Disraeli*, *Nepenthes* *intermedia*, and *Dracaena* *speciosa*.

MR. BULL'S CUPS.—In the class for twelve new plants introduced since the commencement of 1875 Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Sussex, secures the fifteen-guinea cup with *Croton* *chrysophyllus*, very brilliant, *C. trilobus*, *C. Hendersonii*, *Aralia* *filicifolia*, *Artocarpus* *Cannonii*, *Acalypha* *marginata*, *Dieffenbachia* *illustris*, *Aralia* *elegantissima*, *Brahea* *filamentosa*, *Cycas* *Normanbyana*, and *Croton* *imperialis*. Mr. T. Penfold, gardener to the Rev. Canon Bridges, Beddington, Croydon, wins the ten-guinea cup with a really admirable collection. *Aralia* *elegantissima*, *Croton* *Disraeli*, *Lomaria* *Dalgarrensis*, *Anthurium* *candida*, *Artocarpus* *Cannoni*, *Dracaena* *Goldiana*, *Croton* *pictus*, are particularly good. Mr. Tudgey secures the five-guinea cup with smaller plants. Mr. B. S. Williams is the only exhibitor in the nurserymen's class, and receives the fifteen-guinea cup with an admirable collection.

FINE-FOLIAGED PLANTS.—The competition for eight fine-foliaged plants (amateurs) is very spirited, Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Sussex, winning first honours

with enormous plants of *Cycas circinalis*, *Cibotium princeps* very fine, *Encephalartos villosus*, a magnificent *Cycas revoluta*, and *Crotons Youngii*, interruptus, and variegatus 7 and 8 feet high and nearly as many through. Mr. E. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, is placed second with a very fine collection, amongst which is a large and well-coloured plant of *Sarracenia purpurea*; and Mr. Penfold, gardener to Rev. Canon Bridges, Beddington, third. In the class for fifteen fine-foliage plants in pots not exceeding 12 inches in diameter Mr. W. Bull wins first honours with grand examples of *Aralia venusta*, *Pandanus Veitchii*, *Cocos Weddelliana*, *Dracenas amabilis* and *Goldiana*, *Anthurium crystallinum*, a very fine plant of *Phyllo-tænium Lindenii*, *Croton roseo-pictus* in splendid colour, *Curculigo recurvata striata*, *Thrinax barbadense*, *Lomaria discolor bipinnatifida*, *Encephalartos horridus volutus*, *E. villosus*, *E. Caffra*, and *Dion edule*. Mr. B. S. Williams being placed second with *Aralia Sieboldii* aureo-variegata, *Cupania filicifolia*, *Croton Disraeli*, *Pheniceophorum seychellarum*, *Theophrasta imperialis*, *Cycas media*, *Dracenas Mrs. Bause* and *Berkeleyi*, *Verschaffeltia splendida*, *Cyathea Burkei*, *Areca Verschaffeltii*, *Martinezia disticha*, *Kentia australis*, *Yuca aloifolia variegata*, and *Spathiphyllum pictum*. In the nurserymen's class for eight fine-foliage plants Mr. B. S. Williams is in the chief position with a collection composed of grand examples of *Dasyliroton acrotrichum*, *Cocos Weddelliana*, *Cycas revoluta*, *Pandanus Veitchii*, *Croton Youngii*, *Chamærops humilis*, and *Encephalartos Caffra*. Messrs. Hooper, Covent Garden, are awarded the second prize with a smaller but good collection.

For six large Palms, distinct (open), Mr. C. Rann wins the first place with very large and admirably grown plants of *Phoenix reclinata*, *Pheniceophorum seychellarum*, *Latania borbonica*, *Verschaffeltia splendida*, *Areca sapida*, and *Livingstonia altissima*. Mr. Ley, Royal Nursery, Croydon, is placed second with plants somewhat smaller and not so finely developed as Mr. Rann's, yet very good.

FERNS.—For six stove and greenhouse Ferns (amateurs) first honours are awarded to Mr. Child for very fine *Gleichenias dicarpa* and *Mendellii*, *Davallia Mooreana*, *Dicksonia antarctica*, *Adiantum tenerum* and *farleyense*. Mr. Tudgey is placed second with a good collection, and Mr. Douglas third. Mr. Douglas's collection contains a fine specimen of *Todea pellucida*. In the corresponding class for nurserymen Mr. B. S. Williams receives the first prize for very large and very fresh specimens of *Gleichenias rupestris*, and *spelunceæ*, *Davallia Mooreana*, *Asplenium nidus*, *Cyathea medullaris*, and *Dicksonia antarctica*, the whole collection occupying a space of 15 feet by 30. Tree Ferns come from Mr. Bull and Mr. B. S. Williams in the classes set apart for nurserymen, and first and second honours are awarded in the order named. The stems of both collections could scarcely be less than 12 feet high, and those from Mr. Bull are very even and massive. Mr. Wheeler is awarded the second prize in the corresponding class for amateurs.

PELAGONIUMS.—These are excellently exhibited, especially the collections from Mr. C. Turner and Mr. James. Mr. Turner is the only exhibitor in the nurserymen's class for nine plants with *Countess*, *Prince of Prussia*, *Isabella*, *Snowflake*, *Ruth*, *Duchess*, *Great Mogul*, *Claribel*, and *Scottish Chieftain*, this last a remarkable dark-coloured variety. The plants are not large, but are very fresh and excellently bloomed—pattern plants for decorative purposes. In the corresponding class for amateurs Mr. James, gardener to F. Watson, Esq., Redlees, Isleworth, is an excellent first with plants from 4 to 5 feet through—*Princess of Denmark*, *Prince Leopold*, *Duchess of Cambridge*, *Blue Bell*, *Mary Hoyle*, *Snowflake*, *Pompey*, *Claribel*, and *Archduchess*. Mr. James Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, was placed second with plants somewhat smaller. In the amateurs' class for fancies Mr. James is again in his usual place with splendid examples of *Fanny Gair*, *Roides Fantaisies*, *Juliet*, Mrs. Alfred Wigan, *Mirello*, Mrs. Graham, *East Lynn*, *Princess Teck*, and *Madame Sainton Dolby*. We have rarely if ever seen the Fancy class finer than on this occasion, especially those exhibited by Mr. James. Mr. Weir is again placed second. Mr. C. Turner, Royal Nurseries, Slough, is the only exhibitor in the nurserymen's class for fancies, and worthily receives the first prize with *Ellen Beck*, *Nelly Fordham*, *Delicatum*, *The Shah*, Mrs. Hart, *Marionette*, *Lucy*, *Fanny Gair*, and *Roides Fantaisies*.

ROSES.—These are only exhibited by the trade growers, and in the class for nine Roses, distinct, Mr. Turner is placed first, Messrs. Paul & Sons, Old Nurseries, Cheshunt, being second with large and finely developed plants, both growers exhibiting, as they alone can exhibit, splendidly. Mr. Paul staged *Dupuy-Jamain*, *President*, *Madame Margottin*, *Céline Forestier*, *Edward Morren*, *Madame Victor Verdier* (good), *La France*, and *Alfred Colomb*, very good. For twenty Roses, distinct, the size of pots unlimited, Mr. C. Turner is worthily awarded the first prize; and as we have already remarked on the excellence of the group we need now only note a few of the more prominent varieties. *Edward Morren*, *Duchesse de Vallombrosa*, *Star of Waltham*, *Comtesse de Serenyi*, *La France*, *John Stuart Mill*, *Miss Ingram*, *Marquise de Castellane*, *The Rev. J. B. M. Camm* (very free and very sweet), *Céline*

Forestier, *François Michelin*, *Madame Lacharme*, *Princess Beatrice*, &c.

MIGNONETTE.—An extensive collection of Miles's "Spiral" Mignonette is staged both by Mr. Gallop, who has the stock of this very sweet variety, and also in competition for the prizes offered; but on this occasion the individual spikes are not as fine as we have seen them, and all the plants in competition should have been disqualified, the schedule stipulating for twelve plants, whereas twelve pots are exhibited, nearly every pot containing five plants each. Mr. Gallop is awarded the Society's bronze Banksian medal for his collection, and the prizes of £10, £7, and £5 are won by Mr. Meachin, gardener to C. Armstrong, Esq., Woodslee, Withdean, Brighton; A. Chancellor, Esq., The Retreat, Richmond; and Messrs. Vigo Brothers, Withdean Nursery, Brighton.

MISCELLANEOUS COLLECTIONS.—Besides the fine groups of Messrs. Veitch and Bull above noticed, and for which gold medals were awarded, other collections are highly worthy of notice and inspection.

Messrs. Rolliesson & Sons contribute extensively and well to the Exhibition. Their collection of ornamental-foliaged and flowering plants hardy and exotic is a very large one, and is as good as it is great. The same firm also exhibit an unique collection of *Sempervivums*, *Echeverias*, &c., just as such small plants ought to be exhibited—namely, plunged in boxes surfaced with pounded bricks. They also arrange a fine group of double *Pyrethrums* in pots, and are awarded a gold medal.

Messrs. John Laing & Co., Stanstead Park Nursery, arrange a collection combining elegance with richness; the former feature being imparted by Ferns, Palms, &c., the latter by highly coloured bicolor *Geraniums*, tuberous *Begonias*, *Gloxinias*, &c. It is a very fine group and merits the silver Flora medal awarded.

Messrs. Osborn & Son, Fulham, contribute a group of stove and greenhouse plants fresh, green, and healthy, as their plants usually are, also a collection of hardy herbaceous plants, and receive a silver medal.

At the end of one of the tents Mr. H. Boller receives a bronze medal for a small but remarkable collection of *Cactuses*, *Agaves*, *Aloes*, &c., which are worthy of examination by admirers of the grotesque and curious in vegetation. Mr. Croucher, gardener, Sudbury House, Hammersmith, occupies the opposite end of the same tent with larger plants of the same nature from the celebrated collection of J. T. Peacock, Esq., for which a silver Banksian medal is awarded.

Messrs. Lane & Son, Great Berkhamstead, arrange large and gorgeous groups of *Rhododendrons*, also specimen *Ivies*, and receive a gold medal.

Messrs. Cutbush & Sons stage a group of New Holland plants—fresh, bright, floriferous, and altogether good, and are awarded a silver medal.

Messrs. James Carter & Co. contribute a large group of ornamental-foliaged and general decorative plants, including plants of considerable merit, especially a splendid specimen of *Adiantum farleyense*. A silver Banksian medal is awarded for the group.

Extensively and successfully as he has exhibited in the classes Mr. B. S. Williams has yet been able to arrange a miscellaneous group of great merit, and for which a silver Banksian medal was awarded, and Messrs. Hooper & Co. contribute a fine collection of *Echeverias*, *Ixias*, &c.

CUT FLOWERS.—Messrs. Barr & Sugden exhibit a varied, rich, and extensive collection of *Irises* interspersed with Ferns. The rich colours of these hardy flowers almost rival the *Orchids*, and are much admired by the numerous visitors. A silver Flora medal is deservedly awarded. An extensive collection of *Ixias* is exhibited by Messrs. James Veitch & Sons, and attract much attention owing to their very varied and remarkable colours. They are very fine indeed, and are awarded a bronze Banksian medal. From Messrs. Downie & Laird of Edinburgh come an exquisite collection of one hundred *Pansies*, all seedlings of 1877 and 1878, which are very beautiful and much admired. A silver Banksian medal is awarded for them. Mr. Ware, Tottenham, is highly commended for a collection of *Pyrethrums*, representing twelve splendid varieties. From Mr. John Waterer, Knap Hill, come a miscellaneous collection of cut blooms of hardy *Azaleas* in bright and varied colours. Mr. George, Putney Heath, sends three boxes of *Pelargonium* blooms all of his own raising. One box contains eight varieties of Hybrid Ivy-leaved varieties and is highly commended. From Mr. Cannell, Swanley come collections of twenty-four varieties of single *Geraniums*, twenty-four varieties of double, a box each of *Salmon*, *Striped*, and *White Vesuvius*; also a box of *Mimulus* seedlings. These collections produce a brilliant and striking effect. They were highly commended. Messrs. E. G. Henderson & Sons exhibit cut blooms of *Mimulus* of remarkable beauty.

DECORATIONS.—Mrs. J. H. Cousins, Southport, is worthily awarded a gold medal for a collection of skeleton leaves and flowers of remarkable beauty, and a silver medal is awarded to Messrs. Dick Radclyffe & Co. for a rockwork fernery. Messrs. Mortlock & Co. and Mr. Aldous exhibit table decorations.

CERTIFICATES.—First-class certificates were awarded to Mr.

Bull for *Kentia rupicola*, an elegant Fern: and for *Dracaena Bijou*, a gem of the first water, a distinct and brilliant novelty; leaves not more than 4 inches long, bronze, margined scarlet. It is very dwarf, compact, and attractive. Mr. W. Fisher, gardener to T. Williams, Esq., Woodlands, Nightingale Lane, Balham, has a similar award for *Gloxinia Berkshirei*, fine white throat, base of lobes lilac shading to bluish pink; large and fine. Mr. Turner, Slough, was awarded a first-class certificate for *Show Pelargonium Fortitude*; lower petals rich salmon, upper petals velvety maroon, white centre, smooth, and of great substance; very fine.

FRUIT.

The display of this is tolerably extensive, and, considering the earliness of the season, the quality is generally very good indeed, some of the dishes being of great excellence.

In the class for a collection of eight distinct kinds of fruit there are only two exhibitors. Mr. J. T. Miles, gardener to Lord Carington, Wycombe Abbey, High Wycombe, wins the first prize, having very good-coloured Black Hamburg and Foster's Seedling Grapes, President Strawberries, Queen Pine, Black Circassian Cherries very fine, Brown Turkey Figs, Stirling Castle Peaches, and Elruge Nectarines, all good. Mr. Thomas Bannerman, gardener to Lord Bagot, Blithfield, Rugeley, is awarded the second prize; his collection contains a very fine Trentham Hybrid Melon and excellent Grapes; indeed all the dishes are very good.

Pines.—The first prize for two Pines is awarded Her Majesty the Queen (Mr. Jones, gardener) for excellent examples of Smooth Cayenne. The second prize falls to Mr. T. Rutland, gardener to His Grace the Duke of Richmond and Gordon; Mr. Rutland is also awarded the first prize for one Pine Apple—Smooth Cayenne.

Grapes.—Nine collections of Black Hamburg Grapes are staged, Mr. Thomas Bannerman winning the first prize; Mr. Edwards, gardener to Mrs. Tristram, Fowley, Liphook, Hants, the second; and Mr. A. Jamieson, gardener to Earl of Crawford and Balcarres, Haigh Hall, Wigan, the third. The bunches are of medium size and excellent shape, berries very fine and of good colour. For two bunches of white Grapes there are ten exhibitors, and Mr. Edwards, Mr. Bannerman, and Mr. R. Sowerby, gardener to the Earl of Macclesfield, Shirburn Castle, Oxon, are first, second, and third respectively for excellent produce, especially the first-prize collection.

Peaches and Nectarines.—Mr. James Fry, gardener to J. L. Baker, Esq., Haydon Hall, Eastcote, Pinner, is placed first for six Peaches with Grosse Mignonne; Mr. C. Maher, gardener to C. Allhusen, Esq., Stoke Court, second with Crawford's Early; and Mr. J. Horwood, gardener to J. L. Lovibond, Esq., Beckenham, third with Princess of Wales. Nectarines.—Mr. J. Horwood is here placed first with highly coloured Elruge Nectarines; Mr. Sowerby second with the same variety; and Mr. J. G. Seymour, gardener to W. R. Wynch, Esq., Hatfield, third with Pitmaston Orange.

Cherries.—Only one collection of two dishes of Cherries is staged; they come from Her Majesty the Queen and are worthily awarded the first prize. May Duke and Bigarreau are the varieties.

Strawberries.—These are admirably represented. Mr. J. Worthing, gardener to A. Moss, Esq., Chadwell Heath, Essex, is placed first for three dishes, distinct; and Mr. Norman, gardener to the Marquis of Salisbury, Hatfield House, first for one dish of President; the second prize being awarded to Mr. Neighbour, gardener to G. Wythes, Esq., Bickley Park, Kent, with Sir Charles Napier; and the third prize to Mr. J. Bolton, gardener to W. Spottiswoode, Esq., Coombe Bank, Sevenoaks, for British Queen. All excellent examples. Thirty varieties of Strawberries in pots were sent from the Society's garden at Chiswick.

Melons.—These are represented by thirteen fruits. The first prize is awarded to Mr. John Clutton, The Gardens, Aston-Rowant House, Tetworth, for a very fine netted fruit of Gilbert's Victory of Bath; the second prize going to Mr. Miles for a small fruit of Victory of Bath. The third prize is awarded to Mr. W. Pepper, The Lodge, Bromley Common, Kent, for a scarlet-fleshed variety named Sutton's Hero of Bath.

Thirty-six dishes of Apples come from Her Majesty the Queen, and for the season of the year are in most excellent preservation, the generality of them being almost as fresh as when gathered. This collection is highly commended.

VEGETABLES.

These are both extensively and well exhibited, Mr. Miles winning first honours in the collection of ten varieties with very large Asparagus, excellent Tomatoes, well-filled Little Gem Peas, Erfurt Cauliflowers, Porter's Excelsior Potatoes, Tender-and-True Cucumbers, Early White Naples Onion, Fulmer's Early Forcing French Beans, Globe Artichokes, and very fine Horn Carrots. Mr. W. Igoulden, gardener to R. B. W. Baker, Esq., Orsett Hall, is a close second, having the finest Excelsior Tomatoes and William I. Peas in the Show. Mr. W. G. Pragnell, gardener to G. W. Digby, Esq., Sherburn Castle, Dorset, is third.

IMPLEMENTS.—Amongst the implements we noticed "Invir-

cible" lawn mowers (Edwards' patent), exhibited by Mr. Crowley, which have won nearly twenty medals; "President" lawn mowers exhibited by McKenzie & Sons, an American implement which has also won many important prizes; also the "Automaton" lawn mower by Ransoms, Sims, & Head. All of these implements worked smoothly and did their work excellently. Messrs. Smeaton and Co. exhibit their "Surprise" tubular boiler; and Messrs. Hooper & Co. Von Levetzow's self-watering flower pot.

The arrangement of an exhibition of such magnitude is no easy task. The work has been well done, especially in the large marquee, where one collection of plants appears to enhance the beauty of the other. True taste was exercised by Messrs. Veitch in arranging the central group—the key to the whole position—in a manner totally dissimilar from all other collections. With large Roses on the one hand and imposing fine-foliaged plants on the other the central gems shone the brighter, while the surrounding groups were rendered the more imposing by the lightness and the brightness of the central point. This is as it should be, for the simple reason that everybody are the gainers. Grouping the great Roses at the opposite ends of the tent was manifestly the right plan, and not less advantageous was the placing of the competitive "effect" groups of Messrs. Wills and Aldous in juxtaposition; indeed, it is not too much to say that Mr. Barron never arranged the large enclosure more tastefully, correctly, and effectively.

The Exhibition continues open until Friday evening, and we urge all who are able to do so to inspect it, for it may be long before they have an opportunity of looking on the like again.

NOTES AND GLEANINGS.

At the last general meeting of the ROYAL HORTICULTURAL SOCIETY the following candidates were duly elected Fellows of the Society—viz., Captain W. de W. Abney, R.E., Mrs. Gough Arbuthnot, Rev. W. M. Banks, W. Fulford Brown, Lieut.-Col. Henry Thomas Butler, Right Hon. Sir Henry Cotton, John Foy, W. H. Holroyd, T. T. Lawden, William Lee, Mrs. Loch, Mrs. J. Fletcher Moulton, William H. Parry Okeden, Admiral Right Hon. Lord Clarence Paget, K.C.B., Joseph Rowlands, H. R. Sperling, David Syme, Acton Tindal, A. P. Vaughan, and G. C. Wylie. Guinea Members admitted—A. D. Mackay and J. H. Bainbridge.

—THE unique collection of RHODODENDRONS in Mr. McIntosh's garden at Duneevan has been referred to in previous seasons. This year the bloom has not been quite so profuse as usual owing to the cool moist season last year, which induced the shrubs to grow luxuriantly. Many of the trusses are, or rather were a week ago, in great magnificence, all the newer varieties being in superb condition. This is the most complete private collection of these gorgeous shrubs with which we are acquainted, and certainly nowhere can the beauty of Rhododendrons be seen to better advantage, the shrubs being arranged in bold groups on an undulating lawn at the foot of one of Nature's imposing terraces; their brilliant masses of colour relieved by handsome Conifers produce a remarkably rich and picturesque effect. Amongst the Rhododendrons the American and Ghent Azaleas are extremely beautiful. The collection is a very choice one, but only one plant can now be described; it is a seedling raised by Mr. McIntosh several years ago, and now almost entirely fills a circular bed, there being only a small fringe of Rhododendrons at the margin, and the plants composing it must be removed. This Azalea is now about 5 to 6 feet high and the same in diameter, and is one glowing mass of orange, crimson, and scarlet. We never saw a shrub more floriferous nor a lawn ornament more imposing than this remarkable specimen. Some other features of this admirably kept garden will be alluded to, and a reference to the extraordinary manner in which birds are domesticated will be found at other end of this Journal.

—AN extremely fine display of CALCEOLARIAS has for some time past been provided in Messrs. Suttons' nursery at Reading. The flowers are now fading, but they yet afford sufficient evidence of the excellence of the strain both as regards general superiority of the form of the flowers and the great number of varieties. The plants are also very fine, some of them being quite as large as those staged at the London exhibitions. The plants are grown wholly for producing seed, and not one inferior variety could be seen in a large houseful of plants. Another large house is quite filled with *Gloxinias*, to which the firm is giving special attention. Many splendid varieties are noticeable, the foliage of some reflexing and almost hiding the pots. Another structure is filled with tuberous Begonias, and several others with Cyclamens. All the

houses are in excellent order, as are the grounds: in the latter a fine collection of double *Pyrethrums* will shortly be in great beauty. The immense seed stores, offices, &c., of the great firm are simply wonderful by their extent and completeness; and yet they are not large enough for the world-wide trade, and additions and alterations are being made to meet the exigencies of this gigantic business.

CRYSTAL PALACE SHOW.

MAY 24TH AND 25TH.

ALTHOUGH no third prizes were offered in any of the classes the Show was, owing to its having been well timed for occurring between the two great gatherings at Regent's Park and Kensington, a tolerably extensive one and on the whole good—some of the classes excellent. When Messrs. Turner and Paul exhibit Roses in pots, and both of them are in good "form," the public have a treat of no ordinary merit. Both of those celebrated cultivators exhibited magnificent specimens in the class for nine plants, and the prizes were awarded in the order of their names. In the class for eighteen plants in pots not exceeding 12 inches in diameter Mr. Turner was the only exhibitor, and was awarded the premier prize for a collection which we never saw equalled. Most of the plants were in 10-inch pots, the plants averaging 3 feet in diameter, symmetrical half-globes, each plant carrying thirty to forty blooms of splendid quality, and the foliage was as fine as the blooms. Some of the comparatively new varieties were included in the collection, such as *Royal Standard*, *Oxonian*, *Rev. J. B. M. Camm*, *Beauty of Waltham*, and *Madame Lacharme*, all of which were in excellent order, and the blooms of Paul Neyron were equal to the finest we have seen under outdoor cultivation. The amateurs' Roses were not so good as we have previously seen them. The prizes for six plants were awarded to Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, and Mr. Penfold, gardener to Rev. Canon Bridges, Beddington House, Croydon.

Azaleas were a prominent feature of the Show. Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham Hill, always exhibits splendidly at the Palace. He was, however, this year beaten in the great class of nine plants; and Mr. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, may be proud of his achievement. The plants were of uniform size—obtusely pyramidal 6 feet high and 4 feet in diameter at the base, and were densely covered with fine blooms. *Duchesse Adelaide de Nassau*, rosy crimson, was in magnificent condition, and Duke de Nassau had noble flowers. Amongst the lights *Iveryana*, white, and *Criterion*, flesh suffused with lilac, were the most striking. Mr. Ratty's plants were more irregular in size. *Chelsoni* was 7 feet high by 6 feet in diameter, and Mrs. Fay was 8 feet by 6, while others were much smaller. The best white was *Madame Cannart d'Hamale*, and the best of the darker varieties was *Grand Crimson*. This remarkably fine Azalea was raised by Messrs. Jacksons of Kingston, and as a crimson we know of none to surpass it. In the remaining classes for six, three, and eighteen plants Mr. Ratty secured the whole of the first prizes, Mr. Child following rather closely.

Ornamental-foliaged plants of great excellence were staged by Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley; Mr. Tudgey, gardener to J. F. Greswolde Williams, Esq., Henwick Grange, Worcester; and Mr. Penfold, gardener to Rev. Canon Bridges, who were awarded the prizes for twelve plants in the order of their names. Mr. Warren's plants were such as are rarely seen for size and quality combined. They comprised *Latania borbonica*, *Phœnicophorium seychellarum*, *Verschaffeltia splendida*, *Areca sapida*, *Crotons volutum*, *interruptum*, and *variegatum*; *Cycas circinalis* and *revoluta*, *Encephalartos villosus*, and *Dasyliro glauca*. Mr. Tudgey staged smaller but good plants, and exceedingly close in merit were the specimens staged by Mr. Penfold. In this collection *Spathiphyllum pictum* was bold and imposing, as was also the fine *Palm Hyophorbe Verschaffelti*. Ferns were admirably exhibited by Messrs. Tudgey and Penfold, who were placed first and second respectively in the class for twelve plants with collections of nearly equal merit. Many of the plants were large and all of them in excellent health, some in Mr. Penfold's group being remarkable for their rich dark green colour indicative of superior cultivation.

Stove and greenhouse plants were well represented. In the nurserymen's class for nine plants Messrs. Jackson & Sons won first honours with a capital collection, followed by Mr. J. Peed, Roupell Park Nurseries, Lower Norwood, who staged smaller but very good specimens. In the corresponding amateurs' class the awards were made in the following order—First Mr. Tudgey; second Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley; third Mr. B. Peed, gardener to Mrs. Treadwell, St. John's Lodge, Lower Norwood. In the class for six plants Mr. Chapman was placed first and Mr. Peed second. The competition in this class was undoubtedly rather close, and we thought the first-prize collection nearly as good as the second—there is no misprint here. In the class for eight *Ericas* Mr. Peed secured first honours with symmetrical well-flowered specimens, especially

E. exquisita, *E. eximea superba*, and *E. obbata*. Mr. Tudgey had *E. ventricosa coccinea* and *E. tricolor Wilsoni* in superior condition. *Orchids* were not particularly imposing. In the nurserymen's class for ten plants the prizes went in the following order—First Mr. B. S. Williams; second Mr. Henry James, Castle Nursery, Lower Norwood; and third Messrs. Jackson & Sons. In the amateurs' class for eight plants Mr. Child was first and Mr. B. Peed second. Mr. Williams' collection was by far the finest in these classes.

Mr. Turner, Slough, and Mr. James, gardener to W. F. Watson, Esq., Redlees, Isleworth, were the only exhibitors of *Pelargoniums*, and were deservedly awarded first prizes. Mr. Turner's show varieties and Mr. James's fancies well sustained the fame of the cultivators—more than that need not be said. Mr. Parker was the only exhibitor in the class for Alpine and herbaceous plants. The gem of the collection was *Spirea arnica*, the pure white feathery plumes of which were quite charming.

The miscellaneous collections contributed greatly to the value and effectiveness of the Exhibition, and extra prizes were awarded to Mr. F. W. Griffin, gardener to J. Willcocks, Esq., Eliot Bank, Forest Hill, for *Calceolarias* and *Gloxinias*; to Mr. Henry Hooper, Vine Nursery, Widcomb Hill, Bath, for *Roses* and *Pansies*, the latter very fine and in rich and striking colours; to Messrs. W. and A. Smith, The Nurseries, West Dulwich, the decorative *Pelargoniums* in this collection being very floriferous; to Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, for a rich and varied collection of new and rare plants; to Messrs. John Laing & Co., Stanstead Park, Forest Hill, for two excellent groups of ornamental plants, than which none in the Palace were finer; to Messrs. Rollisson & Son, The Nurseries, Tooting, and Messrs. Osborn & Sons, Fulham, for superior collections of fine-foliaged and flowering plants; to Mr. James Ford, gardener to J. G. Megaw, Esq., Church Road Upper Norwood; to Messrs. Carter, Dunnet, & Beale, High Holborn, and Perry Hill Nursery, Sydenham, and Mr. John Wills, Melbourne Nursery, Anerley, for collections of plants; and to Mr. J. W. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, for an excellent collection of cut *Roses*. One of Messrs. Rollisson's groups consisted of an unique collection of *Succulents*—small plants in pots plunged in boxes surfaced with pounded bricks, a most appropriate mode of exhibiting plants of this nature. In Mr. Wills's collection *Dracenas*, *Gloxinias*, and *Yucca filamentosa variegata* were very fine, and in the collection of Messrs. Carter *Casuarina sumatrana* was particularly elegant, and *Coleus Empress of India* was very rich, and *C. Knatchbull-Hugessen* finely marbled. An extensive and superior collection of plants was staged by Mr. Thomson, the able garden Superintendent.

Certificates were awarded to Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, for *Adiantum neo-guineense*, *Calyptronoma Swartzii*, *Macrozamia crenata*, *Ptychosperma rupicola*, *Cycas media*, and *Dracenas Bauseii*, *Berkeleyi*, and *Fredericki*; *Wallichia zebrina*, and *Microlepia hirta cristata*; to Messrs. John Laing & Co., Stanstead Park, Forest Hill, for *Begonias President Burrelle*, fine double scarlet; *Carnicolor*, flesh tinted salmon, dwarf and fine; *Baron L. Leguay*, rosy pink, suffused salmon distinct and attractive; and for *Gloxinia Madame de Stael*, ground white, densely spotted with rose, rose margin, exterior of tube white very chaste, and attractive; also to Mr. Charles Turner, The Royal Nurseries, Slough, for *Rose Penelope Mayo*, which may be described as an improved *Marie Baumann*—that is, having the form and foliage of that fine Rose with a deeper colour.

The plants were arranged in the central transept and north and south aisles of the building, and were displayed to the best advantage on sloping stages devised by Mr. Thomson. These stages were about 18 inches high in front and 3½ feet at the back, and about 8 feet wide. Stages formed in this manner are a great convenience to exhibitors, as scarcely any blocks are required for tilting the plants. Now that the plan is seen to answer its purpose so admirably, and is so simple in its nature, that the wonder is it was not thought of and carried out before.

REVIEW.

Catalogue of Plants under Cultivation in the Government Botanic Garden, Adelaide, South Australia. By RICHARD SCHOMBURGK, Dr. Phil., Director. Adelaide, 1878.

WE have to thank Dr. Schomburgk for a copy of this catalogue, which has just come to hand, and which testifies to the marvellous progress that is taking place in our colonial botanic gardens, and certainly in that of Adelaide. The first edition of this catalogue appeared only seven years ago, and it has already become so obsolete as to already require a new one. In the former there were recorded six thousand species of plants, and in this there is an addition of 2500, making 8500 species in all. This new edition is in every respect an improvement on the first, and the most important point in which it differs is in its being arranged on the natural system, by which it serves the double purpose of being educational as

well as a catalogue. We congratulate Dr. Schomburgk on the remarkably fine collection he has got together.

The catalogue is profusely illustrated with woodcuts of views in the botanic garden, which are evidently taken from photographs, and therefore truthful. We reproduce one of these views (fig. 62), and we cannot but feel that our South Australian brethren ought to be proud, as we have no doubt they are, of their botanic gardens. The picturesque effects produced by the skilful and masterly style in which the grounds are laid out are equal to anything we have seen of a similar description.

In the preface Dr. Schomburgk has printed a very interesting account of the climate of the colony, a part of which we shall now give so as to convey to our readers and to intending emigrants some idea of the country. We must suggest to the author a revision of the list of "Authorities Quoted," in which he notes those who are dead. We are happy to say Robert Fortune is still in the flesh, and hope he may long remain so,

so is De Candolle; but there are many dead who are represented as being alive, such as Andrews, Arnott, Backhouse, the brothers Cunningham, Curtis, Henslow, Hudson, A. B. Lambert, J. T. Mackay, and many others; whilst among the foreign botanists who are said to be living we have the names Palisot de Beauvois, Brongniart, Cels, Delile, Haller, &c.

The following extract from the preface to the catalogue will be read with interest:—"Our summer season includes the months of December, January, and February, when the temperature on the plains frequently exceeds 100° in the shade, and 130° to 140° in the sun. In 1876 the thermometer registered in December $114^{\circ} 2'$ in the shade, and $162^{\circ} 6'$ in the sun. This degree of heat has only been exceeded on two former occasions—viz., in 1865, when the thermometer registered on the 9th January $116^{\circ} 3'$, and the 14th January, 1862, when the reading was 115° in the shade and 165° in the sun. Such a temperature produces very injurious effects on the

Fig. 62.—VIEW IN ADELAIDE BOTANIC GARDEN.

introduced plants, especially those from cooler climes, and leaves even injurious traces on the native vegetation.

"During the blowing of a hot wind the thermometer and the wet-bulb thermometer show often a difference of 30° to 40° , and it is that which enables persons to bear the heat of our summer and carry out their usual pursuits in the field or elsewhere, which in a tropical climate would be impossible.

"The changes of temperature during the summer are often very sudden, so that in a short time the thermometer falls from 90° or 100° to 60° or 70° .

"Our summer months are characterised by great heat, hot winds, and dryness. Often not a drop of rain falls for eight or ten weeks, and it is during this time that not only the indigenous but the acclimatised vegetation suffers materially. The ground becomes so hot and cracks, that even the occurrence of a heavy fall of rain serves only to clear the leaves from dust, as it evaporates as quickly as it falls.

"The autumn season includes in Australia the months of March, April, and May, and is one of our genial and beautiful parts of the year. The temperature falls rapidly, only reaching 70° to 90° in the shade, the mean being $64^{\circ} 6'$, and in the month of May it is only $58^{\circ} 2'$. The northern winds become cooler, the solar radiation is considerably reduced, and heavy dews begin to fall at night. The indigenous vegetation which

has suffered through the summer awakes to new life, and trees and shrubs put forth fresh growth, while the leaves of the European deciduous trees and shrubs get their autumnal tints and drop.

"June, July, and August constitute our winter, our rainy season, which is usually marked by frequent rain and strong winds; but it happens also often that we have to content ourselves with remarkable dry winters, the mean temperature during the three months being 54° to $55^{\circ} 7'$. Heavy hoar frosts and frosts appear often during night. The lowest temperature registered in 1876 and '77 during the month of July has been 30° and 28° , the lowest experienced in the plains near Adelaide. Such heavy frosts have most disastrous effects upon the tropical and subtropical plants in the gardens.

"The spring season, the most genial and most beautiful in South Australia, not surpassed in any other part of the world, includes the months of September, October and November, the mean temperature during the first two months being 60° to 70° .

"At this time of the year the gardens are in their best floral beauty—trees, shrubs, perennials, annuals, emulate each other in regard to their flowers, which are of such size, richness in colour, and perfection as a northern gardener can scarcely imagine. But early-appearing hot winds in November destroy those floral beauties in the course of a few hours.

"The average fall of rain during the year in the plains of Adelaide is 19 to 21 inches, but the distribution is unequal, even on plains not far apart, each showing a great difference in the rainfall.

"In the Mount Lofty Ranges, about eight miles distant from Adelaide, the average of rainfall is 40.677 inches.

"According to our indefatigable Government Astronomer, Charles Todd, C.M.G., the lowest rainfalls have been in 1850, when only 11.644 inches fell; in 1859, 11.647 inches; in 1857, 12.650 inches; in 1854, 13.437 inches, and in 1871, 14.926 inches. The highest fall near Adelaide was in 1875, when 31.455 inches fell.

"This climatic sketch refers only to the plains around Adelaide. In the southern parts and in the hills the temperature is much cooler, and the rainfall, as already mentioned, much heavier.

"From the foregoing it can be imagined that not all the plants from other countries will thrive with us.

"The Alpine and tropical ones suffer not only from our dry atmosphere, but the latter also from the cold during the winter months. In the hills the Alpine plants and those of other cool countries grow exceedingly well, but the tropical plants are destroyed by the frosts, which in such localities are even severer than on the plains."

SEEDLING AMARYLLISES.

THE reading of "AMATEUR'S" letter, which appeared in your Journal under the heading "A Plea for Amaryllises," brings before my mind's eye the brilliant and gorgeous display of these flowers which I saw at Chatsworth the other day, where they are very extensively and successfully grown. In several departments of Chatsworth gardens the Amaryllises are at the present time charmingly attractive, being well grown and full of flower. "AMATEUR" talks of the Amaryllis going into disrepute and disuse owing to the difficulty of raising good seedlings, and then says, "that for every good variety raised hundreds of worthless seedlings have been produced and, unfortunately, not destroyed, and these form the bulk of the bulbs offered for sale," &c.

Mr. Speed has been trying to raise good Amaryllises from seed, and has been very successful with crossing *Ackmanii pulchella* and *reginæ*. I did not ask which of these two was the seed-bearing plant, but by crossing these two he has raised a great number of beautiful seedlings, and not a bad or worthless one amongst them. By perseverance he has struck on the right thing at last, for he has now seedlings of his own unsurpassed for beauty and distinctness of colour. The rich crimson and pure white of the Chatsworth seedling Amaryllises strike one from every point of view. Mr. Speed was, like other people, unsuccessful with other sorts. He crossed *Johnsonii* with *Goviana*, and from two hundred bulbs raised from seed of this crossing not one was worth keeping. He is now on the right track, and judging from the number of seed pods I saw ripening on some of his plants I guess that year after year we shall have a greater display of Amaryllises in the gardens of Chatsworth.—A. PETTIGREW.

ROYAL BOTANIC SOCIETY'S FLOWER SHOW SCHEDULE.

I ENCLOSE to you a schedule of the Royal Botanic Show on the 22nd. In Class 23, twelve *Gloxinias*, I was an exhibitor, and was disqualified because I had two of one sort. You will see that the schedule does not specify twelve distinct. I had not overlooked this; I had looked at the spirit of the schedule. In Class 7 the word "distinct" is used; in Class 8 it is used again, "ditto" not even being allowed to serve. In Class 18, 8-inch pots, and in Classes 19 and 20 the figure and word are used; ditto, or a number of dots, are not to be trusted, so explicit were the framers of the schedule. I am aware that to show two of a kind is a point of weakness, and of course taken advantage of in close competition; but as our plants were so far superior I felt no hesitation on that point. It is singular that everyone I came in contact with read the schedule as I did. Even my fellow exhibitor was candid enough to admit it. I leave to you and others to judge who is to blame. The Judges, perhaps, gleaned what was the meaning of the framers of the schedule, and they acted accordingly. It is no interest of theirs who the prize should be awarded to. I fear my only recompense is the satisfaction that I exhibited twelve as good plants for the size of the pots as any that have been shown

lately.—W. P. ROBERTS, *Gardener to W. Terry, Esq., Peterborough House, Fulham.*

[Your plants ought not, according to the schedule, to have been disqualified.—EDS.]

ALSTRÖMERIA CHILENSIS.

"G. B., *Birmingham*," in recommending the culture of *Alströmerias*, especially for affording cut flowers—a recommendation which we endorse—requests information respecting the Chilean *Alströmeria*, its origin and culture. Mr. Thompson of Ipswich believes it was raised by M. Van Houtte from seeds imported from Chili; but the species appear to hybridise so freely that this circumstance is not altogether conclusive of its distinct character. The flowers vary considerably in their tint, some of the specimens producing blossoms much darker than others.

Alströmeria chilensis is of the easiest cultivation, requiring only to be planted in moderately rich soil of a sandy texture, where it will flourish for years with but little attention. It

Fig. 63.—*Alströmeria chilensis*.

grows about 2 feet high, and the roots will when two or three years old produce several stems, each terminated by an umbel of from ten to twenty blossoms, which expand in July and August.

The plant will not succeed in stiff loam and therefore, when the soil of the borders is of this character, an artificial compost must be prepared of sandy loam, decayed manure, and leaf soil or peat. It will be advisable to plant the roots at a depth of at least 4 or 6 inches; they will then be not only less liable to injury from severe frost, but will also suffer less from drought in summer. In dry weather during their growth they will require a frequent supply of water, and when in flower the stems, being somewhat feeble, must be supported by neat sticks. In shallow hot soils neither this nor any of the species succeed well.

READING SHOW.

WHEN a worthy organisation answers its purpose it deserves encouragement and support. The Reading Horticultural Society has been established many years, and many exhibitions have been held under its auspices. The last was on the 23rd inst., and it is evident both by its extent and quality that the district of Reading contains excellent cultivators, and that the Society has stimulated them to put forth their strength in producing exhibitions of which any town may be proud. By the exercise of economy and general good management the Committee are able to provide some good prizes; but we should be glad if an additional number of subscribers should enable them to offer more, as we observe that in nearly half the classes only two prizes were provided at the Show in question, and that many meritorious exhibits had to

go unrecognised and their growers unrewarded. A royal county and thrifty and prosperous town ought not to permit this.

The site of the Show is an appropriate one. Its approach is through a garden tolerably extensive, diverse in its attractions, and enjoyable. The Forbury Gardens, belonging to the Corporation of Reading, and to which the inhabitants of the town have access, are well kept and managed by Mr. Phippen the local nurseryman. In these gardens the ancient and modern are represented. Ancient Elms crown the large central mound, and old-fashioned herbaceous plants crowd some of the borders, while modern spring bedding at one season and carpet bedding at another are well carried out in the beds. Shrub groups are banded with Iberises, Japanese Honeysuckles, *Stachys lanata*, and such-like permanent yet effective plants. There are, besides the scrolls of flowers well disposed on the extensive lawn, gracefully curved walks, shady nooks, Ivy-clad banks, rocky promontories, and a rosery, the Rose beds being edged with a singularly cheerful hardy plant more bright than the Golden Feather—namely, the Golden Marjoram. At the extremity of the gardens are the Abbey ruins, and it is under the shade of the venerable and massive Ivy-mantled walls that the Mayor permits the Society to arrange the exhibitions. For these permanent provision has been made, and made well. The centre is a large rectangular depression, to which sloping walks lead from the four corners. From this centre terraced banks have been formed for accommodating the plants. At the top of these a broad walk conducts round the enclosure, having on its opposite side—the sides of the tent—other grassed banks, the boundary. When arranged the appearance of the Show was that of a grand flowery dell. It was one of the best and most beautiful local displays that we have seen for a long time.

In noticing the leading collections we must first refer to the Royal Horticultural Society's prize—the Veitch memorial medal with £5 for three stove and greenhouse plants in bloom, Orchids excluded. This prize was won by Mr. Parham, gardener to G. May, Esq., Reading, with a *Stephanotis* 4 feet by 8 in grand health and bloom, a similarly sized and equally good *Clerodendron*, and a central plant of *Lantana* "Le Grendier." We have never seen a *Lantana* so admirably grown and trained as was this splendid specimen. It was an obtuse pyramid about $4\frac{1}{2}$ feet in diameter at the base and $8\frac{1}{2}$ high, perfect in every part as a plant could well be, and covered with orange-scarlet flowers. As an exhibition plant this *Lantana* when thus grown is equal to any *Rondeletia*. Mr. Mearing, gardener to W. Whitley, Esq., Guildford, was a good second. His *Ixora Lobbi* was very fine, but the other plants were too closely tied.

In the class for twelve stove and greenhouse plants three excellent collections were arranged. Mr. Lees, gardener to Mrs. Marshall, The Wilderness, Reading, secured the premier position with two *Azaleas* 7 feet by 4, *Clerodendron* and *Allamanda* nearly equally large, *Stephanotis*, *Bougainvillea*, *Pimelea*, and *Erica ventricosa grandiflora*—all good; *Aphelaxis*, *Erica eximia superba*, and *Franciscia calycina major*, smaller. The two last-named plants were in splendid condition, indeed just "pulled off" the prize from Mr. Tudgey, gardener to J. F. Greswolde Williams, Esq., Henwick Grange, Worcester, whose collection contained a vigorous plant with ten spathes of *Anthurium album*. Third honours were won by Mr. Mearing; the plants were generally over-tied. The gem of the collection was a plant $2\frac{1}{2}$ feet in diameter of *Lechenaultia biloba major*; it was much and deservedly admired. In the class for six plants Mr. Parham won the foremost place. A *Rhynchospermum* 4 feet by 8 was in fine condition, *Cactus superba* with forty gorgeous blooms, *Clerodendron*, *Bougainvillea*, *Anthurium Scherzerianum*, and *Erica Cavendishiana*, a small but admirable plant, comprised the collection. Mr. Pewsey, nurseryman, Pevensey, had the second prize. His *Hederoma*, *Erica Cavendishiana*, and *Aphelaxis* were excellent, but the remaining plants weak. These collections had an imposing effect, and the Judges, Messrs. Barron and Dean, were long in deciding on their merits. In the amateurs' class for four plants Mr. Higgs, gardener to Mrs. Crawshaw, Caversham Park, and Mr. Baskett, gardener to N. J. Palmer, Esq., were placed in the order named with creditable specimens. The first collection was composed of a *Rhynchospermum*, *Anthurium Scherzerianum*, *Stephanotis*, and *Aphelandra*. Orchids do not call for comment. Mr. Baskett was awarded the first prize for three very small but healthy plants, and for a single specimen also small. There were seven entries in the class for single specimen stove or greenhouse plants. Mr. Atkins, gardener to Col. Loyd Lindsay, Lockinge Park, Wantage, was first with a grand *Clerodendron* 5 feet by 4 and faultless; Mr. Tudgey was second, also with a *Clerodendron*; and Mr. Baskett third with *Pimelea mirabilis*, a fine plant, but old and flowers small. In the corresponding class for fine-foliated plants Mr. Atkins won with an excellent *Cocos Weddelliana* 7 feet high, with large and healthy fronds. Mr. Rose, gardener to C. Eyre, Esq., Welford Park, Newbury, was second with a good *Dasylirion*. Mr. Mearing for *Sarracenia flava* with thirty-five pitchers and Mr. Lees with *Cycas revoluta* were equal third.

Pelargoniums.—For nine plants Mr. Baskett was first and Mr. Ashby second with creditable specimens about 2 feet in diameter,

good in bloom and foliage. For four plants (amateurs) Mr. Ashby won with dwarf healthy grown plants. Mr. Higgs second. *Fancies*.—Mr. Miller, gardener to C. Ellis, Esq., Waltham Place, won first honours with plants $1\frac{1}{2}$ foot across; they were fresh, full, and very good. Mr. Baskett was second with small compact half-globes, and Mr. Ashby third with larger plants but irregular. Several of the *Pelargoniums* were not trained sufficiently low. *Fuchsias*.—For six plants Mr. Lees won with loose columnar examples, but foliage good and flowers fine. For four plants Mr. Mearing was first and Mr. Mayne, gardener to R. Large, Esq., second with stout healthy pyramids 4 to 5 feet high and 8 feet in basal diameter. *Gloxinias*.—A capital class. Mr. Baskett was first with good plants and varieties. Mr. Pile, gardener to J. J. Wheble, Esq., Bulmershe Place, second, also good, and Mr. Ross third with small plants of superior quality. Mr. Mearing exhibited the finest plants, but they were damaged, and Mr. Goddard, gardener to G. Marshall, Esq., Windlesham Hall, Bagshot, exhibited a collection grown from seed supplied by Messrs. Sutton & Sons; evidently an excellent strain. *Calceolarias*.—Mr. Mearing was first with dwarf well-grown plants in Mr. James's style; Mr. Mortimer, gardener to Major Storer, Sulhamstead, second with larger and taller examples; Mr. Baskett third with smaller plants, heads a foot across, dwarf, fresh, and of good quality—a very good class. *Roses in pots*.—Mr. Baskett, Mr. Mould, and Mr. Lees were placed in the order named in the class for six plants; and in that for four plants Mr. Lockie, gardener to Lord O. Fitzgerald, Oakley Court, Windsor, and Mr. Tranter, Upper Assenden, were awarded the prizes. The plants were naturally trained—that is, their shoots were not bent into "form," and each plant carried eight to twelve good blooms. They were useful decorative plants. Some other collections were staged, but they were very inferior. *Ericas*.—The plants generally were healthy, medium-sized, or 2 to 3 feet in diameter, well bloomed, and attractive. In the class for six plants Mr. Lees had the first place. *E. depressa multiflora* and *eximia superba* were very fine indeed, *Cavendishiana* and *tricolor superba* were larger, also good. Mr. Mould was second with larger plants. *E. ventricosa magnifica* was in capital order in this collection. *Azaleas*.—In the class for nine plants Mr. Higgs was placed first with pyramids 5 feet high, and Mr. Lees second with healthier but not such well-bloomed examples. In the class for four plants Mr. Miller was first with attractive standards; stems 3 feet high, heads a foot in diameter, healthy, and well bloomed. Mr. Parham was second with dwarf floriferous plants in 7-inch pots.

Fine-foliated Plants.—Although some good specimens were exhibited yet the collections were not generally so meritorious as the flowering plants. In the class for nine plants Mr. Higgs had the chief prize for a good collection, which included admirable examples of *Alocasias metallica*, Lowii (very fine), and *Veitchii*, *Palma*, *Trec Ferns*, and *Cordylines*. Mr. Tudgey was second. *Kentia australis*, *Areca Verschaffeltii*, *Croton Johannis*, and *Cycas revoluta* were good in this collection. Mr. Elliott had third honours. In the class for four plants Mr. Atkins won the chief place with *Cycas revoluta*, *Maranta Veitchii*, *Calathea zebrina*, and *Croton variegatus*. The plants were not so large as those in the other collections, but they were well worthy of their position. Mr. Lees was second; his *Pandanus Veitchii* was good, and *Croton Weismannii* exhibited by Mr. Mearing was in fine colour. The plants in some of the collections in this class were irregular in size and were deficient in freshness and brightness.

Table Plants.—There was great competition in this class. Mr. Ross was placed first with *Pandanus Veitchii*, *Dracena Cooperi*, *D. Guilfoylei*, *Croton Weismannii*, *Caladium argyrites*, and *Adiantum gracillimum*, all fresh and bright. Mr. Atkins was second with *Aralia Veitchii*, *Croton Weismannii*, *Cocos Weddelliana*, *Dracena nigra rubra*, *Dæmonorops fissus*, and *Adiantum gracillimum*; and Mr. Tudgey third with newer and choice plants but too small. All the plants were in 6-inch pots.

Ferns.—These were as a rule very meritorious. In the class for nine stove and greenhouse Ferns Mr. Mortimer, gardener to Major Storer, had the premier award for a really admirable group, comprising *Polypodium angustifolium*, *Adiantum concinnum latum*, *A. cardiocladum*, *Gymnogramma chrysophylla*, *Nephrolepis exaltatum*, *Leucostegia immersa*, *Lomaria gibba*, and two *Phlebodiums*. The plants were from 8 to 4 feet in diameter, and were very fresh and healthy. In the class for four plants Mr. Atkins was first with *Davallia Mooreana* and *Adiantum tenerum*, *trapeziforme*, and *farleyense*, about 8 feet in diameter and very good. Mr. Mearing was second with generally larger plants, and Mr. Parham third with small, compact, healthy specimens.

Lycopods.—These were splendid, especially the first-prize collection of Mr. Mearing. They were handsome cones 2 to 4 feet high. Mr. Higgs was second also with good examples.

Groups of Plants.—These constituted a prominent feature of the Show. For effective arrangement of plants in a space of 12 by 10 feet Mr. Parham won with comparative ease. The group was treated with great boldness and freedom. At the back were tall healthy plants of *Musa*, *Grevillea*, and an *Acacia*. In the centre of the space a good flowering specimen of *Cereus flagelliformis* grafted on the tall stem of a *Cactus* was very effective,

Two panels were formed of dwarf flowering plants, a rather tall Palm springing out of each, and a few sprays of Orchids. In the front were a capital *Erica Cavendishiana*, *Anthurium Scherzerianum*, *Caladium argyrites*, *Panicums*, *Gymnostachyums*, and Ferns. If this group had a fault it was rather too much crowded. Mr. Lees was second; his back plants—*Fuchsias*—were tall and good, the remainder were flowering plants and Ferns tastefully associated. *Scutellaria Mocciniana* was very effective in this group. Mr. Baskett had the third prize. The prizes for the smaller groups of 6 feet by 4, which were very bright and cheerful, were awarded to Mr. Elliott, gardener to T. Hibbert, Esq., Braywick Lodge, Maidenhead, and Mr. Burbidge, gardener to B. Symonds, Esq., in the order named.

Cut Flowers.—The collections of twelve and six bunches of stove and greenhouse cut flowers were very good indeed. Mr. Tegg, gardener to J. Walter, Esq., Bearwood, was first in the class for twelve, but the award did not give general satisfaction on account of *Primula japonica* and *Maréchal Niel* Roses being included. Messrs. Miller and Tudgey had the remaining prizes. In the six class Messrs. Ross and Mortimer were the prizewinners with excellent collections. Mr. Robins, gardener to E. Dyke Lee, Esq., Hartwell House, Aylesbury, won the first prize for twelve cut Roses, and Mr. Tranter the second. The blooms were fresh and good. Bridal and button-hole bouquets were very tastefully arranged. Messrs. Phippen and Robinson won the chief prizes for the former with a pleasing arrangement of *Stephanotis*, Lilies, and *Gauze Fern*. The latter were composed of small Rose buds and spray of *Forget-me-not* and other small flowers and Fern. Messrs. Ross, Atkins, and Phippen were the prizetakers. In the ladies' classes for vases of flowers, foliage and Grasses were very good, especially those decorated with wild flowers. Miss Phippen, Miss Cooper, and Miss Robinson appear adepts in this mode of decoration. A charmingly simple arrangement of Buttercups and Grasses by Miss Bourke, St. Giles' Vicarage, was highly commended by the Judges.

FRUIT.—Black Hamburgh Grapes from Mr. Ogston, gardener to the Countess of Yarborough, Titness Park, Sunninghill, and Mr. Ashby, who were awarded the prizes in the order named, were excellent and well coloured. White Grapes were also good. Mr. Ashby was first with Foster's Seedling, and Mr. Tegg second with Buckland Sweetwater. Strawberries were splendid. Mr. Bridgeman, gardener to T. Somers-Cocks, Esq., Thames Bank, Great Marlow, had the first prize for a dish of thirty fruits of Lord Napier weighing 22 ozs. Mr. Lockie was second with the same variety. For Peaches Mr. Tegg was first with Grosse Mignonne, very good; and Mr. Ashby second with Early Ascot.

VEGETABLES were very well exhibited, especially Potatoes and Cucumbers. Mr. Howe, gardener to Sir R. Sutton, Benham Park, Newbury, had the first prizes for both round and kidney Potatoes, the former with Rector of Woodstock, the latter with Lee's Hammersmith Kidney. In Cucumbers Mr. Mearning was first with Tender-and-True, and Mr. Lockie second with Duke of Connaught. Messrs. Sutton & Sons also offered prizes for Cucumbers, and brought out good competition. Mr. Lockie was first with Master-piece, 18 inches long and very regular; Mr. Higgs second with Model nearly 2 feet long; and Mr. Tomlin third with Duke of Connaught 18 inches in length. Mr. Spring, gardener to Lord Camoys, Stonor Park, Henley, was first in the class for a collection of vegetables, and Mr. Read second, both exhibiting capital produce. Other prizes were awarded, but we cannot enumerate them.

We congratulate the members of the Society and exhibitors on their excellent Show and on the arrangement of the several collections. The staging of exhibits, however, was not completed until twelve o'clock instead of ten—a grave fault, for when judging has to be done amidst a crowd of visitors no one can be surprised if mistakes occur, although, with one trifling exception above referred to, the awards appeared to give general satisfaction.

THE THRIPS.

FAMILIAR as this insect is to the majority of cultivators there are yet many, judging by the examples of Vine leaves sent to us infested with thrips, to whom the insect is not known nor understood. The accompanying figure and description will enable anyone to recognise it if it is infesting their Vines or plants, when no time must be lost in destroying it, for it is one of the worst pests that can gain a footing in our stoves and greenhouses. Our drawing represents this insect highly magnified, while the short line upon the scroll intimates its natural length.

The larvæ and pupæ are yellowish white, and the perfect insect is of a dull deep black, with the point, and sometimes the whole of the abdomen, of a rust colour; the wings are dirty white, the horns and legs yellowish, the extremity of the former black. It attacks plants by piercing the under side of the leaves, and one often sees at the tip of the tail a globule of blackish fluid which it soon deposits, and by innumerable

spots of this glutinous matter the pores of the leaves are stopped up, and large portions of the surface become blotched. During March the full-grown larvæ and pupæ, which are as large as the perfect insect, are found in groups feeding on the under side of the leaves, and at this time the recently hatched but perfect insect either lies close under the ribs or roves about in search of a mate (*Curtis*).

Fig. 64.—The Thrips.

Fumigating once a fortnight the houses in which it is present is a good means to adopt for eradicating it; and we have found that syringing the plants, &c., infested with a solution of soft soap and tobacco water is also effectual if applied once a week at a temperature of 100° or 120°. Prevention, however, is better than cure, and if the plants are kept healthy by due ventilation and abundance of moisture both in the air and soil, this insect may be usually banished.

SUBTROPICAL GARDENING FOR AMATEURS.

If the owner of a small garden were to ask how to convert it into a subtropical garden *à la* Battersea I should certainly be disposed to answer, Don't. "A SUBSCRIBER" does not ask this but sends a request for some hints for amateurs upon the subject. Gladly do I hasten to respond, for the matter happens to be one upon which it is desirable a little light should be shed, erroneous ideas as to what may be done in this direction in small gardens being very prevalent. I wonder if it was a reader of the *Journal* who was indulging in a growl over one of the magnificent groups at Battersea last summer—growing because his own gardener had not been so successful in his culture and grouping in the little garden at home. If so, let me say to him with my other readers, Pray consider ways and means before you resolve to enter upon a competition with a large public garden having the advantage of a Government grant, even if your aspirations point only to the reproduction of the arrangement of a single bed or group.

Subtropical gardening if carried out in its entirety is a costly process, involving a considerable outlay both of time and money. There are, however, certain modifications of it comparatively inexpensive, and which may fairly be said to be within the scope of most amateurs. To make this clear it is only necessary to classify the plants available for the purpose under three distinct heads; these are Annuals, Hardy Perennials, and what may be termed Tender Perennials.

By turning his attention solely to the culture of hardy plants, the amateur who has no glass houses may nevertheless impart a tone and boldness of style to his garden which, if not strictly subtropical in the common acceptance of the term, will yet bear an impress of dignity and freedom from heaviness and formality which are eminently desirable.

Hardy plants, then, as being most useful and easily cultivated shall be taken first, and among the best we have *Bocconia japonica* or *Jeddensis* with its curious orange-coloured stems, handsome foliage, and tall feathery spikes of white flowers springing up to a height of 7 feet. *Centaurea babylonica*, a somewhat coarse-looking but not unpicturesque plant, also a tall grower. *Heracleum giganteum*, a fine bold plant, telling well either alone or in the centre of a clump. It will grow to a height of 10 feet, but unfortunately it loses its freshness early in the season, and for that reason should not occupy a too prominent position. Strictly speaking it is a biennial coming into flower the second year and dying as the seed ripens. *Rheum Emodi*, a handsome plant, remarkable for its red-veined leaves. I have not grown this, but saw it in

a flourishing condition in Mr. Carne's garden on the north coast of Cornwall last year. *Rhus glabra laciniata*, the curious and elegant dwarf Sumach, has been much cultivated during the last few years, its graceful red-hued Fern-like foliage rendering it desirable and useful for beds and clumps. *Yucca recurva*, *Y. filamentosa*, and *Y. gloriosa* are all worthy of a place, telling well either singly upon lawns or terraces, or in picturesque groups on hanging banks, or among rocks. *Acanthus latifolius* and *A. spinosissimus* are both fine plants with bold elegant foliage. The flower spikes of *latifolius* are both curious and ornamental, and those of *spinosissimus* are on strong plants quite a yard in height and much brighter in colour than *latifolius*. *Gunnera scabra*, a dwarf plant with curious huge leaves, is very ornamental. It should be planted in a sheltered damp situation in deep rich soil. *Arundo conspicua* answers well in the southern counties, its beautiful drooping plumes being in perfection quite two months before the Pampas Grass, which it is said to equal in height, but I have not seen it as yet above 7 feet, and judging from the slender appearance of the foliage, and, in fact, of the entire growth, I do not think it is likely to much exceed that height. *Arundo Donax* is also a fine ornamental Reed, putting forth its plumes with the Pampas Grass, to which, however, it is much inferior. Its variegated variety, *A. Donax versicolor*, is also quite hardy in the south. Then we have *Ferula communis* with its beautiful, glossy, finely divided foliage; the huge-leaved *Crambe cordifolium*, *Geranium anemonifolium*, a handsome hardy plant, forming bold green tufts upwards of a foot in height, enlivened with numerous purplish pink flowers in early summer. It has answered best with me in an elevated position among some rocks, dying down in winter and springing up again in April. *Statice latifolia* also answers best in a dry well-drained position with a good depth of rich soil. Its large foliage is ornamental and forms an admirable foil to the greyish blue flowers which spring upwards to a height of from 1 to 2 feet. *Dictamnus Fraxinella* with its handsome dark green foliage and pink flowers is a very ornamental plant, and withal one of our oldest favourites, as is also the charming Feather Grass (*Stipa pennata*), just now throwing up its slender plumes. In the southern counties many of the Cannas occupy an important position among hardy plants, but in the cold north they have to be taken up and stored like Dahlias. *Melanthus major*, one of the very best plants in a subtropical garden, is now also left out all the winter in the south, and although it is cut down to the ground by frost, new growth springs from the roots in spring, and is more effective than that of ordinary pot plants. I had almost forgotten the stately *Ailanthus glandulosa*, which in its young state is so beautiful. It has, however, to be cut down annually or otherwise replaced with young plants, so as to secure single stems of stout new growth in order to have the foliage in perfection. *Catalpa syriaca*, *folia* and the Golden Elder (*Sambucus nigra aurea*) are also strikingly effective in a young state.

Next in usefulness to the hardy plants come the Annuals, most of which must be raised early in heat and brought quickly on in pits, or other glazed structures, where plenty of space can be afforded them, in order to bring them to a considerable size before they are planted out when the settled hot weather comes in June, and therefore any cultural hints would be useless for the present season. I may, however, usefully note that many of our best plants are so raised—such as *Solanums*, *Ricinus*, *Cannas*, *Ferdinandia eminens*, *Acacia lophantha*, *Nicotianas*, *Acanthus*, *Melanthus major*, *Ferulas*, *Humea elegans*, *Wigandia caracasana*, the best of its genus; the less stately *W. urens* and *W. Vigieri* also both come from seed.

Lastly come those costly plants which I have termed Tender Perennials, most of which have been repeatedly enumerated in these pages. Now, amateurs do not generally possess a large quantity or many duplicates of such plants, and I must strongly urge the importance of caution in venturing to expose any new or rare plant. Most well-known varieties of Palms bear exposure well, so do *Ficus elastica* and *F. macrophylla*, which may either be planted out or plunged in the turf. Tree Ferns, too, answer in sheltered shady dells. "A SUBSCRIBER" complains that of a *Rhopala De Jonghii* which he put out upon his lawn last summer the leaves become spotted, turn brown, and fall off. Let him apply the lesson and keep it indoors in future; for such a plant, which he now states has recovered, has plenty of beautiful young foliage and is 5 feet high, is much too valuable to be exposed to such risks.

The reports of the summer planting of the beds at Battersea Park and other public gardens which have been given in the

Journal annually for so many years render details of arrangement unnecessary here, and, indeed, little good could be done in that direction unless one could take each garden separately; and if any of my amateur readers become puzzled they have only to submit their plans and arrangements to head quarters at Fleet Street to secure efficient counsel and aid.—EDWARD LUCKHURST.

NOTES ON VILLA AND SUBURBAN GARDENING.

CONSERVATORY.—With a rise in the temperature flowering plants remain a shorter time in beauty now than in the earlier part of the season; consequently, in order to keep the conservatory always gay, a complete overhaul is more frequently rendered necessary, the structure being refurnished with other plants just coming into bloom intermixed with fine-foliage plants. The climbers must be regulated by having their growths neatly secured, and if at all infested with insects war must be waged against them. Azaleas which have done flowering should have all decaying flowers and partly formed seed-pods picked carefully off, and the plants placed in a moist warm temperature, so that a good healthy new growth may be made. This is very important, for on it depends in a great measure the setting of the flower buds for next season's blooming. Syringe the plants frequently, and fumigate against thrips, to the attacks of which the Azalea is very subject. Those plants that flowered early and have made their new growths may be placed in a cold pit prior to being turned out of doors to ripen their wood. Camellias thrive well under exactly the same treatment, with occasional waterings of soot water.

Roses in pots that have ceased blooming will require a little attention to prepare them for another year. The whole of the plants must now be carefully repotted in good silky yellow loam and decayed manure, and be plunged in an open space out of doors, which will establish them for next year. It is not always necessary to pot them into larger pots, but a portion of the old soil can be shaken from them or removed with a pointed stick, the plants being returned to the same sized pots again, always using new or well-washed pots. Dirty pots are not only unsightly, but the plants do not thrive in them so well as in those that have been washed and dried before being used. When the plants are making new roots and growth careful attention is requisite in watering. When fairly established liquid manure should be given to them at frequent intervals. It is with Roses as with many other plants, if a good foundation is not established while growth is being made the qualities of the flowers are very inferior the following season. For Tea Roses a much lighter soil is requisite, therefore mix a proportion of leaf soil with the loam and thoroughly decayed manure mentioned above. Remove all flower buds as they form, and stop any rampant shoots, or they will deprive other portions of the plants of necessary support. Some cultivators do not report their Roses until the autumn, but there is a decided advantage in potting them immediately after blooming.

Richardia athiopica is a most useful plant and will endure much hard usage, but to grow the plants well they require liberal treatment during the summer months. One of the easiest and best methods of increasing both the size and quantity of the flowers is to divide the plants at once and plant them out in a well-manured trench similar to a trench made for Celery. If water is given them plentifully during dry weather they will grow very rapidly and make very fine plants before frosty nights set in, when they should be taken up and potted. We have seen some very fine flowers produced in this way, and the plants almost take care of themselves, with the exception of watering as directed. For the decoration of churches, or for associating with other plants from November onwards, we know of no plants so useful and at the same time lasting in flower so long as *Richardias*. *Schizostylis coccinea* succeeds and flourishes admirably under exactly the same mode of culture; it is very valuable for affording a supply of bright flowers during the dark days of winter. *Spiræas*, *Lily of the Valley*, *Deutzias*, and such-like plants should also be divided and planted out in a spare piece of ground kept as a reserve garden. They will here form new crowns and take care of themselves until the time comes for taking them up and potting for forcing another year.

Summer bedding should now be proceeded with with the utmost dispatch. The weather has been very wet of late, so that the beds are in good order to receive the plants. The spring-blooming plants must be divided and planted regularly that they may form good plants for future work. *Polyanthuses*, *Daisies*, *Pansies*, &c., are increased in this way, but *Wallflowers* (single), *Myosotis*, *Silene*, *Collinsia*, and such-like annuals are best raised from seed. *Hyacinths* and *Tulips* should be taken up carefully and be placed in light sandy soil on some warm border to ripen, when they may be stored away for the season. After removing the spring-blooming plants give the beds a liberal dressing of rotted manure, and dig it deeply in, when they will be ready to receive the summer-flowering plants.

PITS AND FRAMES.—Cucumbers are now growing very rapidly in frames; the growths must not be left to become a tangled mass or they will soon exhaust themselves. Carefully thin out any crowded shoots and stop others. A dose of liquid manure at times will impart extra vigour to the plants. We have by careful management made a three-light frame afford a supply for several months. If there is any fear of the supply running short raise other plants either from seeds or cuttings, and prepare a slight hotbed to plant them out in. The true Telegraph variety is one of the best and freest to fruit of the whole race. The frames and pits which have protected the bedding plants throughout the winter should be turned to account for growing both these and a late crop of Melons. They will require less heating material now than in the earlier part of the year. Melons require a much heavier soil than Cucumbers, and Victory of Bath and Munro's Little Heath are comparatively hardy sorts.

WORK FOR THE WEEK.

KITCHEN GARDEN.

MAKE another sowing of late Peas, which should be the last for the season, except in particularly favourable situations. Any sown after this time should be of the early kinds. A last sowing of Broad Beans should be made. Attend to earthing-up and staking the crops of Peas as they advance, also Runner Beans, which should have the stakes placed to them before they are much grown. A sowing of Lettuces and Radishes should be made every fortnight. In dry soils and warm situations they are best sown for the next six weeks upon a north border. Rampion seed should be sown in drills 9 inches apart, thinning the plants to 6 inches. If sown earlier the plants are liable to run to seed. The seed is very fine and must only be just covered with soil. Cabbages as cut should be cleared off the ground, unless the ground can be spared to allow them to grow, in which case they will afford a capital supply of small heads and sprouts for use in late summer and autumn. A first sowing of Endive, both the Broad-leaved and Curled, may be made. Well ventilate late crops of French Beans in frames, keeping them and also Carrots well supplied with water.

Mushroom Beds.—Beds made as before advised will soon be in bearing. If not, and buttons are not already showing, we advise the first watering to be of hot water—a good surface sprinkling, with a view to the destruction of all insects harbouring about the surface. The bed after watering should be covered with hay which has been well beaten upon a hard floor with long sticks, and slightly damped as beaten. The beating will remove from it all the small parts and render it more tough and pliable, and in removing it is not so liable to injure the button and stalked Mushrooms as ordinary unprepared hay. It should be put on 2 inches thick. The first watering will generally require to be given about four weeks after the bed is made; but if the bed were cold at spawning or only slightly warm it will probably not require water so soon by a fortnight, as in the warm bed (75° to 80°) the spawn will run more quickly than in that of a bed spawned at 70°. The bed should have become dry before any water is given, and not afterwards allowed to become again very dry at the surface.

HARDY FRUIT GARDEN.

Fruit trees generally are making such splendid growth that stopping or pinching will require to be attended to earlier than usual. We, as a rule, do not advise the pinching to be done until the leaves to be stopped back to are full-sized. Shoots, for instance, that are to be stopped to three leaves will not have these full-sized until the shoots have twice the number of leaves. However, the growths are now so luxuriant that stopping is absolutely necessary with Apricots, Plums, and Pears. Any shoots that exceed 3 inches in length should be stopped at the third leaf, leaving the short spur-like shoots untouched. Shoots required for extension and to fill vacant space must not be stopped but trained in their full length, excepting the centre leader, which in the case of Pears or Apples horizontal-trained should be stopped at 12 to 13 inches length, and it will generally push three shoots from the uppermost joints, two available for training horizontally and the other upright as leader. Plums and Cherries are best fan-trained, as when horizontal training of these trees is resorted to the lower branches not unfrequently become so weak as to die off. The branches should not be nearer than a foot whatever mode of training be practised, though in fan-trained trees they of course of necessity must for some distance from the point of origination be at a much closer distance. Morello Cherries and Apricots must have the shoots nailed-in wherever space admits and shoots are available. Forerights and shoots not required for training stop at the third leaf; but strong forerights remove altogether or pinch to one joint. Bush and pyramid trees will shortly require attention, indeed some of them are in need already. We presume that the branches are from 9 to 12 inches distance apart, and that throughout their length are furnished with spurs; these of course will not need stopping, but all free-growing shoots upon the main branches must be pinched to three leaves and to one afterwards, their leads to six, and the leading shoot of the

tree to 12 inches, allowing shoots to remain as may be required for filling-in not nearer than a foot. If this be attended to trees will be had with open heads admitting light and air to every branch. Morello Cherries endure pinching well, taking out the points of the shoots at from the third to the fifth leaf. There is an advantage in stopping the shoots when insects are prevalent, as they generally infest the points of the shoots. If the shoots are placed in a basket as they are removed and promptly burned much present and greater after trouble will be saved.

FRUIT HOUSES.

Vines.—Early houses which have been cleared of fruit should have a thorough washing with the garden engine to cleanse the foliage from dust and red spider, admitting air liberally. The borders inside must have water to keep them moist. The laterals keep in check by stopping, unless the foliage is unhealthy and the Vines weak, when the laterals may be allowed to extend, their growth having an invigorating tendency. A liberal and constant supply of warm air must be afforded Grapes ripening off, maintaining a moist, sweet, genial atmosphere in houses where the fruit is swelling; closing early on fine afternoons with plenty of moisture, so as to husband as far as possible sun heat and save fuel. Muscats, and particularly Lady Downe's, when completing the stoning process are liable to scald in bright weather and should be carefully watched, seeking to lessen the evil if it appear by early air-giving and liberal ventilation during the day for about a fortnight, when danger from scalding will be past. Late Grapes in flower should have a constant circulation of dry warm air, with a temperature of not less than 70° at night and not exceeding 90° as a maximum by day. Vines in light soils not unfrequently suffer from dryness; such should be well watered and mulched in dry weather. Vines in full growth can hardly be overwatered, the borders being well drained, but avoid driblets; one good watering is worth fifty sprinklings. Crops swelling off should have a little guano sprinkled over the surface of the border previous to watering; it is of service in assisting the swelling, and a good mulch will keep the border moist for some time longer than were none applied. The thinning of Grapes ought not to be delayed a day after they become fit for the operation, for they soon become too large to be quickly thinned and have a good appearance. Keep the laterals well attended to in stopping, it being disastrous to allow them to grow and remove them in quantity. Cut off all badly placed, small, or otherwise undesirable bunches, cropping lightly, aiming at high finish rather than bulk. Grapes intended to hang late should be well thinned, particularly in the interior of the bunches.

Vines in pots raised from eyes inserted in spring, or cut-barks grown-on, should be stopped when 8 or 9 feet long, the laterals and sub-laterals being stopped to one leaf. This more particularly applies to those intended to fruit next season, as by close stopping the eyes are "plumped" and the wood hardened. Those intended for planting-out need not have the laterals stopped at all. This is a good time to plant out Vines from eyes struck in February and grown-on in pots or turves. The roots will not have become much twisted and need not be disentangled, or only such as can be done without breaking up the ball. Water well at a temperature of 90° to 100°, and mulch with a couple of inches of short dung; keep up a moist atmosphere, and shade from bright sun until established, maintaining the temperature to 70° at night, 75° by day, rising to 85° or 90° with sun and air, closing at 80°. With good management a moderate crop of fruit may be had the following season. It is necessary at this time of year to give air early in the morning, as the sun coming in contact with the moisture condensed upon the foliage during the night causes scorching unless air has been previously given.

Peaches and Nectarines.—A good succession of Peaches and Nectarines may be had by a judicious selection of varieties, Early Beatrice, Early Louise, Early York, Royal George and Noblesse ripening in succession. In Nectarines Lord Napier is succeeded by Elruge. Admit air very freely in the daytime, leaving some on at night. The temperature may be gradually reduced but not allowed to fall below 60° at night, or a check may be given resulting in a loss of foliage. The border should have a good watering when the fruit has been gathered; syringe the trees to cleanse the foliage of spider and dust. In succession houses the tying-in of the shoots, stopping, &c., must be attended to, syringing twice a day. The watering of inside borders will require more frequent attention now that warmer weather may be expected. Any leaves that shade the fruit should be removed after the fruit commences swelling after stoning, so that the sun and air may colour them equally. Keep the shoots thin in the latest house, as this is important in securing the ripening of the wood. In houses in which very little fire heat is employed mildew occasionally appears. If specks of white appear upon the fruit rub sulphur upon them and dust the foliage with it. Aphid is best overcome by repeated fumigations, but the foliage must be dry, and the fumigations moderate and repeated as often as necessary. Strong fumigations are dangerous. It is important that Peach houses be ventilated early in the day, and that the top lights be not entirely closed at night.

Strawberries in Pots.—Those in cool houses and frames are

swelling-off their fruit. The plants should be watered two or three times a day according to the weather, and have liquid manure two or three times a week until the fruit commences colouring, after which give water only sufficient to prevent the foliage from flagging; this with plenty of air is conducive of flavour. It is astonishing what fine fruit is obtained from plants in pots half plunged in soil in cold frames. A span-roofed frame 4 feet wide will hold four rows, the plants a foot apart every way, a 60-foot length holding 240 plants. The fruit requires to be trussed-up; and whether from the plants rooting into the soil and enjoying greater moisture, or the dry warm air afforded by the frame, the lights being opened about 6 inches on each side, the fruit is certainly finer and higher in flavour than that had by other means. We not infrequently place the frame, after the crop is had from those in pots, over those in the open ground, it covering two rows of plants; and in a wet season such sorts as Dr. Hogg, British Queen, Filbert Pine, and Premier so liable to spot, are very much improved in flavour. When the fruit is cleared off the plants they should be at once taken out of the houses, as they mostly are infested with red spider, which soon spreads through the house if there be any delay in their removal.

FLOWER GARDEN.

The planting-out of Coleuses and Alternantheras may be proceeded with provided they have been duly hardened off, otherwise it is best to defer planting for a few days. Subtropical plants, such as *Ricinus*s, *Solanums*, *Wigandias*, *Aralias*, &c., should be at the time of planting staked and securely tied to prevent them being injured by the wind. In geometrical designs there is often too much flatness, which is easily broken by a few plants of *Palms*, *Yuccas*, *Dracenas*, tall succulents, &c., which judiciously placed break the monotony of formal arrangements and impart grace and beauty. Attention must be paid to watering and shading such plants as require it; pinching, pegging, and otherwise regulating the growth so as to have the lines of colour clearly defined. A sowing of annuals for late bloom may now be made, also sow *Mignonette* plentifully in a sheltered situation and well-drained soil for securing a supply of spikes late in the year. Annuals sown previously will now require thinning if not already done. It is no use expecting a fine display of flowers if the plants have not space to attain full development. Stocks, Asters, Marigolds, and other half-hardy annuals raised in cold frames will now be ready for planting out. They like rich soil and an open situation. Herbaceous plants should be attended to with stakes—i.e., such as require it. This department of the garden should not be neglected, for the time is coming when flowers from under glass will not be so plentiful, and a well-stocked herbaceous border will afford much that is useful for cutting. No department of a garden affords such interest for the labour bestowed on it as that containing hardy plants.

TRADE CATALOGUE RECEIVED.

John Laing & Co., Stanstead Park Nursery, Forest Hill, S.E.—*Catalogue of Store and Greenhouse Plants, Florists' Flowers, Vines, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

DOUBLE VARIETY OF *CARDAMINE PRATENSIS*.—"An Old Subscriber" says it is found in Lancashire growing with the ordinary single specimens.

LIXIA FLOWER (*Lady W. G. O. E.*).—The colour is not uncommon.

VALUE OF LARGE ORANGE AND LEMON TREES (*Mrs. Owen Lloyd*).—Large Orange and Lemon trees upwards of thirty years old and very fruitful are undoubtedly of considerable value, and may be worth ten or fifteen guineas apiece, or even more if they are in tubs and are really fine, healthy, handsome trees. It is impossible to give a more explicit answer without seeing them.

REMOVING SHOOTS AND RODS OF VINE (*A Constant Reader*).—Mrs. Pince with us fruits freely upon the spur system, it being quite unnecessary to train it upon the rod system, which is what we presume is meant by its bearing only on last year's wood. It appears that you crowd the shoots too much. We should train up one only of the shoots from the base, removing all the shoots upon the rod above it not bearing fruit now, the "old rods" being removed so soon as the fruit is cut, or if no fruit be retained they may be removed so soon as the shoot from the base is in free growth. Let the shoot grow until it reaches the extent of the space, then stop it. Stop the laterals at the first leaf and allow the sub-laterals to make three or more leaves before again stopping, provided there is space; but if likely to crowd stop them at every leaf. In autumn you will have a strong cane. When the leaves fall cut it back to 6 feet from the bottom of the trellis. Before growth commences depress the upper part of the cane so as to induce it to break equally throughout its length. Rub off the shoots so as to leave those for

permanencies at 18 inches to 2 feet distance on opposite sides of the rod, training the uppermost as leader, which should be treated similar to its predecessor, and in early winter it may be cut back to within 6 feet of its base. The side shoots should be stopped two joints beyond the fruit, if no fruit two joints beyond the first tendril, stopping the laterals at the first leaf. The shoots cut back to two eyes after the leaves fall, and the shoots that proceed from them should show fruit. This (the spur system) will be better than the rod, particularly as you intimate that your house is too crowded, the cause unquestionably of the unfruitfulness of this very fruitful Grape. The house being too shaded, we presume by overcrowding, by all means remove the Trebbiano, especially as it does not perfect its Grapes.

REPOTTING *AMARYLLIS* (*Idem*).—After flowering turn the plant out of the pot, divide it, preserving all the root possible to each bulb, and pot in pots about twice in diameter that of the bulbs. We do not employ larger than 7-inch for the largest bulbs. The pots should be well drained, the soil worked in among the roots, the bulb with its base nicely covered with soil, leaving about three-quarters of an inch below the rim for water. Shade for a few days until the potting is recovered from, keeping the soil moist, then afford a light situation and keep the plants well supplied with water. Turfy yellow loam with a fifth of well-decayed manure is a suitable compost, but we omit the manure, and feed during growth with weak liquid manure.

GREENHOUSE SHELVING (*Etc.*).—Iron shelves may be had of any horticultural builder, but they are very much more expensive than slate shelves and not so durable, as they are constantly being wasted by rust, though if kept well painted the objection ceases. Slate is more expensive but cheaper in the end than wood shelves. The slate shelves should have brick, stone, or slate supports, wood soon decaying. For ordinary greenhouse shelves latiss 1½ inch broad and 1 inch deep, fixed 1½ inch apart to bearers 3 inches by 2 inches, narrow surface upwards, at 2½ feet apart, having uprights of the same strength to support the bearers, one end of the bearers being let into the wall, form a very suitable stage or shelf very much more durable than solid wood shelves, and otherwise more desirable. Painted three or four coats stone colour they last a long time, sound well-seasoned timber being employed, and painted not more distantly than every second year.

COARSE LAWN GRASS (*E. M. S.*).—The coarse grass which spreads so fast and is so difficult to eradicate is couch grass, *Agropyrum repens*. You will not get rid of it unless the whole of the turf and 2 or 3 inches of soil is pared off and burnt, but we strongly question the necessity. Frequent mowings will render the growth of all coarse grasses comparatively fine. At this season of the year all lawns require mowing at least twice a week. A scythe ought never to be used upon your plat of about five square perches. You have a mowing machine. To use it with ease the grass must be kept short; let it be so kept, and you will not have any very coarse herbage—certainly nothing to offend the most critical eye. Give this plan a fair trial, and if you are still dissatisfied with your lawn pare the turf and burn it so as to ensure the entire destruction of the creeping stems of the couch grass, dig and break the soil finely, spreading the ashes among it, make it quite level, roll it, rake it, sow the seed, and again pass the roller over it. This may be done either in September or March, and a sharp look-out kept for the birds, which are fond of the seed. The first few mowings must be done with the scythe. Pay close attention to mowing and rolling, and you may bring such a lawn into decent condition in a single season. Three pounds of seed would be enough. This should consist of the mixture of fine lawn grasses, Trefoil, and white Clover, which is prepared by many of the large seed firms whose advertisements appear in this paper. Weeds are quite certain to spring up among the grasses and must be pulled up.

INSECT ON VINE (*R. T. Higham*).—*Coccus vitis*. There is a portrait and full relative details in our "Vine Manual." (*J. K.*).—They are thrips, which usually succumb to repeated fumigations. You will find reference made to this insect and its eradication in another column.

INSECT IN POTS (*J. H.*).—The specimen you enclosed had escaped. Send one in a box.

NAMES OF PLANTS (*Cranfordian*).—Send a specimen when in flower. (*G. Todd*).—*Diplacus puniceus*. (*X.*).—The Gold-weed referred to in a former paper of "The Home Farm" is *Ranunculus arvensis*, or Corn Crow-foot. (*W. C. E.*).—*Prunus Padus*, or an allied species. (*C. T.*).—*Habenaria bifolia* (*H. chlorantha*); not uncommon. (*Arthenice*).—1, *Symphytum orientale*; 2, *Smyrniolum olusatrum*; 3, *Sinapis alba*; 5, *Rosa Banksie*; 6, specimen insufficient. (*Horace*).—The flower is that of a *Ceanothus*, but do the leaves belong to it?

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

"QUARTER EVIL" OR "BLACKLEG" IN CATTLE.

THIS subject has lately been prominently brought to the notice of cattle breeders by the death of a pedigree shorthorned heifer belonging to Mr. George Fox of Elmhurst, near Lichfield, Staffordshire, who states in a letter published in the *Agricultural Gazette* as follows:—"On the 14th of March last I lost by death my red heifer, the Duchess of Elmhurst, out of imported Duchess of Airdrie, twentieth, by Duke of Geneva, ninth (28,391). The disease of which she died is locally known as 'blackleg' or 'quarter evil.'" In taking up this subject with the view of illustrating the causes of this fatal malady, we shall occasionally quote from Mr. Fox's letter, adding such remarks as in our own experience and that of professional veterinary practitioners apply to the subject. Mr. Fox states as follows:—"The Duchess of Elmhurst was calved on November 17th, 1876, and consequently was sixteen months old. She was always a particularly robust and healthy animal, very round in the rib, covered with a coat

of fine mossy hair, short in the leg, and what is called a 'good doer.' During last summer most of her time was spent in the open pastures, running with a nurse cow. At 'taking-up time,' say the middle of October, she was drafted with eight others of almost the same age as herself into an open yard with covered sheds, in which they have been kept all the winter." We shall quote the dietary further on.

With reference to the system of management there seems at first sight but little to complain of, or likely to predispose animals to this malady. It is, however, a case of blood poisoning—that is to say, an abnormal state of the blood, being too rich and becoming dark-coloured and defibrinated (as stated by the veterinary authority in the *Agricultural Gazette* in connection with this subject on the 25th of March last). It therefore becomes a question how far the treatment or management of this animal contributed towards the state which produced its death. The nurse cow appears to us a superfluity for so long a period as ten months, and may be credited with having produced in this case a plethora of too rich and consequently unhealthy blood, particularly when the heifer was probably living on pasture sufficiently rich and forcing to have maintained her in good condition without any assistance. We in consequence must consider under the circumstances the policy of using the nurse cow as very questionable, and it very probably may have laid the foundation of the future disaster.

Referring to the accommodation in the winter of an open yard and sheds, these, unless they are properly constructed, may be very bad for cattle although well littered with straw, for unless sufficiently drained so that no water may underlie the bedding, when animals lie down they may take a chill and produce inflammation and symptoms almost equivalent to blood poisoning. A shed to be healthy should have the floor raised at least a foot above the level of the open yard, and if covered with a good layer of dry earth or ashes so much the better. We will now quote Mr. Fox's statement as to the feeding, &c., whilst in the yard and shed. The morning meal "consisted of 1 lb. of linseed cake mixed with 'chop' (hay and straw) and a small quantity of long meadow hay; during the day an open crib supplied with oat straw or rough hay; the last meal at night was the same as in the morning. The little herd were turned out to water morning and afternoon, and, weather permitting, went into a small paddock for two or three hours in the day for exercise. Under this treatment all the animals have grown well, but are in store condition only. For about a month past, in addition to the above, the animals have had half a pound of crushed oats and about 7 lbs. each of pulped Swedes added to the morning's mixture." In this mode of feeding we can discover no reason to induce the belief that the food in the yard had anything to do with producing blood poisoning. We do not, however, know as to the purity of the water, and it is just possible that some impurity might have had some injurious effects. Still the fact remains that the feeding in the yard was too low considering the heifer had the assistance of a nurse cow all the summer previously. This heifer died at the end of about twenty-four hours after the disease was first noticed, and this circumstance is strictly in accordance with the known fatal effects of "quarter evil." We have had stock that suffered from it, and never knew any case where the animal recovered from the attack. At the same time we have had the best advice from clever and experienced veterinary surgeons, who declare there is no remedy after the attack.

We now have to consider the most important points in connection with this subject, because, if there is no remedy, we must look to prevention and precautionary measures. We can quite understand the feelings of a cattle breeder like Mr. Fox upon the death of such an animal; for although we are informed that this heifer was worth, or would have sold for five thousand guineas, yet this is a loss of money only, which wealthy individuals can bear without serious derangement of their affairs, but not so with the loss of a shorthorned heifer of such a pedigree. To any man who is enthusiastically fond of well-bred cattle of any breed success will not always so far attend his endeavours in breeding full pedigree stock as to insure him such an animal as we are remarking upon, let his judgment be what it may in following out all the requirements of breeding, such as judicious selection and mating the animals. In our own experience we every year lost some of the most thriving heifers when they were allowed to feed on the pastures and lie out at night. After this continued loss, instead of using any remedies we merely kept them in small yards and sheds in pairs, the space being 12 feet by 12 feet under cover, and 12 feet by 20 feet in the open, and for a number of years we never lost a single heifer. They were kept thus until they dropped their first calf. We do not advise this practice to those who have pastures to be fed, but merely allude to it as showing that certain pastures actually favour the "quarter ill," and more particularly we find it the case when the pastures are low-lying near a brook or a rivulet where night fogs prevail. We are strongly of opinion that sheds and yards which lie low and below the fog level are dangerous quarters for cattle to be wintered in, even under the most careful management. It is said and believed both by practical men and veterinary surgeons that certain

pastures predispose or render young cattle liable to the attacks of this malady, and our own experience quite confirms this view of the subject.

With respect to treatment of young stock by introducing a seton or rowel in the dewlap, it is always best to have it done by a competent veterinary; but the first question which arises is the age at which to insert the seton. Some parties contend that it should be done at the age of six or seven weeks, but we have never known it done so soon. We consider that from three to four months is sufficiently early, particularly if they are treated only as calves receiving milk, and only turned out at daytime for exercise and housed at night and in bad weather. It is also an important question as to how long the seton should remain in active operation, for, strictly speaking, setoning is done upon the principle of counter-irritation. It is only reasonable to suppose that unless it is continued until the heifers are in calf, and thus be passed the usual period at which they suffer from this complaint, that they would still be in danger if the seton is allowed to fall into disuse in the interim. This raises the question, How is it that heifers whilst in calf are not usually attacked by "quarter evil"? We think that it may be explained in this way—that during the period of gestation the nourishment required by the foetal calf absorbs any excess of richness in the blood. We are, however, strongly of opinion that there is still the constitutional predisposition in certain animals to make more and richer blood than can be utilised, which often shows itself in the "drop" or "puerperal fever" in the cows at calving time. The evidence in favour of the seton is too strong both for practical men and professional men to disregard it, and particularly when the animals are given occasionally doses of saline mixture. For this purpose it is recommended that half an ounce each of nitre and chlorate of potash and 1 to 2 ozs. of Epsom salts be given dissolved in a pint of warm water. We again quote from the veterinarian article in the *Agricultural Gazette*, advising that the various "causes known to engender 'quarter evil' must be sedulously avoided; young cattle must be kept steadily thriving without check from birth."

In this unfortunate loss of the Duchess of Elmhurst we are left comparatively in the dark by Mr. Fox's statement upon some important points—viz., he does not state whether a seton was ever used; he does not state the situation of his meadow land, or his yards and sheds, whether they are low-lying or otherwise; nor does he say if the cattle on this property are more than usually subject to this disease. The turning point of the whole matter to our mind rests upon that which nobody has alluded to—that is, ascertaining by bleeding the state of the animal's blood. The post-mortem examinations of animals dying of this complaint are uniform in describing the state of the blood as being the cause of death, and as setoning cannot be considered an infallible remedy still it is the best precaution in use. As it is admitted by all that the best doers are the most liable to be attacked, would it not be a wise precaution, as supplementary to setoning, to take from them at certain periods say a pint of blood from the neck vein? and if the blood exhibited a great deficiency of fibrine then the treatment may proceed in such a way as to avoid forcing food and too liberal a supply of the albumenoides, such as decorticated cotton cake or bean meal. It must not, however, be supposed that we object to a generous diet for young cattle, but we wish it to be borne in mind that animals thriving rapidly, making blood quickly, with the symmetry and quality which are the indications of profitable feeding, furnish the largest proportion of cases of "quarter evil." It is to these that we wish to call attention, and recommend, in addition to setoning, that the animals should be bled occasionally, carefully noting the state and composition of the blood after standing by for a few hours. Amongst all the heifers that we have bred up under cover from birth, and which have been killed for beef, we have never had a case of "quarter evil," although they had led a life of quietude without exercise under the highest feeding with which we were acquainted. Yet it is said by veterinary authority that want of exercise is one of the predisposing causes of the malady.

We cannot conclude this subject without reference to our own thoughts with regard to the maintenance of a herd of the most valuable and purest pedigree animals, especially of Shorthorns, that such animals have been for a long period bred, fed, and cared for by management in such a manner as to constitute them as exceptional stock, in fact almost artificial animals. As such they ought not to be treated as ordinary stock, whether we look at them from a money point of view or as animals upon which we have set our mind and made it our pride and our pleasure to possess them. We cannot, therefore, advise that any person having a herd of such splendid stock as the best tribes of pedigree Shorthorns should attempt to treat them only as ordinary horned cattle, believing that they will often be disappointed of either pleasure or profit by such management. These observations are especially addressed to the home farm managers, as this stock is generally kept in smaller numbers in such cases, and the details required for successful management can be the more easily attended to.

This disease is neither infectious nor epidemic, and is almost

wholly confined to young cattle from one to two years old. When first discovered the animal appears dull and heavy, and walks lame as if sprained. In a short time a swelling takes place in some part of the body, as on the legs, shoulders, under the belly, or on some part of the back, but especially in the hind quarter or thigh, hence the name of the disease "quarter ill." These swellings are at first soft, but soon a quantity of air is generated in them by the extravasated blood, particularly in the cellular membrane situated between the skin and the flesh, which produces a crackling kind of noise when they are rubbed or pressed by the hand. The mouth and under the tongue are sometimes affected with blisters, which arise from the severity of the fever, the pulse also being quicker than natural.

WORK ON THE HOME FARM.

Horse Labour.—The teams have had more lost time than is usual in the month of May. Some of the preparations for roots are in arrears, particularly on land intended for Swedish turnips; in fact there are some cases where the mangold has not yet been sown. Under these circumstances the horses will now be the more required to complete the cultivation for roots, and in most cases at this advanced period the scarifier will be more useful than the plough, and the land be ready earlier to receive the seed. The field grasses will now be ready for cutting, and should the weather turn to dry all hands will be required in cutting and making the hay. As the carting and rickling of hay often comes at the busy time of turnip sowing this should be anticipated by having everything ready, so that no time may be lost when the hay is fit for the stack. Bavins or faggots may be got ready on the spot for making bottoms for the hayricks in those cases where there are no permanent rick stands. We may here state, when the season for hay-making is adverse and the hay coming to hand in doubtful condition, and where there is plenty of good sweet straw of either wheat, barley, or oats, it is recommended to use some in layers whilst making the hayrick, particularly when it is likely to overheat. The straw will not only tend to diminish and prevent excessive heating, but will when cut out prove superior fodder in consequence of having imbibed the aroma from the hay. The seeds for roots should now be provided, also the manures—such as guano, bone dust, and superphosphate—should be purchased and got home, and placed in the manure shed ready for use. The ashes intended for mixing with manures should also be screened and prepared ready for mixing and drilling with artificial manures. All this work should be anticipated and got ready to hand, in order that in the busiest time there may be as little delay as possible in the work of the farm.

Manual Labour, such as hoeing beans, peas, potatoes, &c., is very much behind with the season in consequence of the succession of heavy rains; in fact where the hoeing has been done the weeds have in many cases struck root again. In the case of beans and peas another hand-hoeing will be almost impossible owing to the rapid growth induced by the late showery weather. Potatoes may be horse-hoed and hand-hoed for some little time yet if the weather should turn favourable. In horse-hoeing potatoes all the weeds may be destroyed, but not so with the couch, and in order to free the land we send women in advance of the horse-hoe a day or two previous and fork-out the couch, otherwise this will increase enormously in good land in the high cultivation requisite for potatoes. The odd horse will now be employed in carting green fodder for all the animals on the farm, and sometimes there may be work for two horses and carts, because where the green crops are used for the cart horses, the dairy cows, the horned cattle under cover, and the pigs also, a large quantity may be required. This may be supplemented by the grass round the borders, banks, and ditches of the fields, and will keep young cattle and pigs, particularly breeding sows, in capital condition, and tend to keep the fencing of the farm in a decent state. Some pastures whilst being fed by dairy cows are much infested by the common buttercup as it is called, producing yellow flowers, which is very pernicious and distasteful to the cows, and affects the quality of the butter injuriously, it being of a very hot and acrid taste. We therefore run the scythe lightly over the pastures, taking off the flowers when at full head. After this we find that the cattle eat the grass much better, and after being cut down once they do not appear again in sufficient numbers to injure the feed. The shepherds will now be busy, as the shearing time for sheep has come; and in cold showery seasons with sometimes rain at day and white frosts at night, the animals after being shorn should be got into a barn or sheltered yard for a few nights. We have known many sheep killed by being exposed at night in some adverse seasons. In some of the southern and south-western counties where the horned sheep are kept the rams will now be put with ewes, and particularly the off-going ewes to be sold away for producing early lambs. In these cases we like to shear the rams a month before being turned out, but the ewes are not shorn until they have offered to the ram.

MR. O. E. CRESSWELL, has been requested by H.R.H. The Prince of Wales to undertake the office of a juror for the show of poultry

at the Paris Exhibition. Mr. Cresswell has accepted the office, which is entirely an honorary one.

BANTAMS.

(Continued from page 384.)

CLEAN-LEGGED Rose-combed Bantams, both Black and White, are extremely attractive; they, too, are active on the wing, but not such determined flyers as Game Bantams. Many people seem not to know that all poultry may be kept within bounds by clipping the primary quills. These are naturally tucked under the secondaries when the wing is closed, and so the bird's appearance is in no way damaged by the operation. Black Bantams should of course be of a rich sheeny black all over, Whites of the purest white, and both should have round smooth white earlobes. There is some difference of opinion as to the proper carriage of these varieties (at least of the Blacks, and the standard of form would seem naturally the same for both varieties), some fanciers preferring them with wings carried well up like Black Hamburgs, others like the Bantams of old with wings touching the ground. We hardly admire the latter type, but certainly like to see their heads well thrown back, and this carriage is generally accompanied by wings drooping more than those of Hamburgs. The Black variety is very popular, and classes for it at the greater shows are always well filled. We find them capital layers, hardy and easy to rear. We once had Whites, but found them delicate and by no means so productive. We do not at all believe in the old theory that white birds are necessarily delicate, but this variety has been neglected and left in the hands of one or two fanciers; hence probably it has been in-bred, and so has become weakly. The Rev. F. Tearle of Gazeley Vicarage, Newmarket, has the best yard of Whites that we know of. There is little competition in the class, and it would be an interesting breed for a young fancier to take up. White Bantams should have white legs; we have seen blue legs even in prize pens, but think them an eyesore.

Sebright or Laced Bantams—the production during this century of a scientific and indefatigable fancier, Sir John Sebright—are surpassed by none in beauty. Each feather must be evenly and moderately laced or edged with black, and that this marking may be uniformly carried out the cocks must have hen tails with no approach to sickles. They are content with very small quarters; indeed we have seen a pen happy and healthy in a Dove's aviary. It is true that they are by no means productive, but in some cases this is a great advantage both to themselves and to their owners. Children's pets have a habit of outgrowing in number the accommodation of their quarters. Tender hearts cannot bear to have a favourite killed, and the stock suffers from this mistaken kindness. Sebrights when small and highly bred will give little trouble on this score, a large number of their eggs generally being infertile.

Booted Bantams are very quaint. When in good plumage and condition the Whites are very handsome. Blacks are rare and generally have many red feathers, though we have seen a capital pair shown by Mrs. Holmes of Bath. They, too, are content with small quarters, and we strongly recommend them as pets to those who do not exhibit at the great shows. To those ambitious of winning high honours they seem extremely troublesome, for it is most difficult to keep their foot feathers in good order: they break on grass, or on gravel, or in straw, or after being long wet. We once had a lovely little fellow of this breed lent to us for his portrait to be taken, and we shall never forget the precautions lest he should spoil his beauty. He lived in a large exhibition pen on a floor covered with chopped hay.

Japanese Bantams are extraordinary little creatures—worthy fowls for so peculiar a people. They must by no means be confused with Japanese Silkies, a totally distinct breed, of which we shall speak another time. At first they strike one as a dwarfed and not symmetrical breed, but their ways are so amusing that they soon become favourites. They are the dummies of the Bantam tribe, very short on the leg, with large heads and combs and immense tails; their legs are yellow. The lighter colours were formerly most admired, but a lovely dark pair brought from Japan in the "Sunbeam" by Mrs. Brassey deservedly took the fancy of most judges at the great shows of last winter. Then as to Pekins. Well, it is a cruel satire to recommend them when we cannot suggest how or where to procure them. Those in England are, we believe, all descended from a single pair taken at the sacking of the summer palace of the Emperor of China. We know of but two possessors of them, and hear that they now breed very badly. A cross with Nankins might invigorate the race and prevent its becoming extinct. We once advertised for some, but the only result was a shoal of letters to inquire if we possessed and would sell them. They should be exact and tiny counterparts of Buff Cochins. They have the placid confident air of Cochins, which makes them look charmingly happy and contented in a little show pen. Of the rarer and now less known sorts we consider Nankins by far the most attractive. They are fair layers, too, of singularly large eggs for their size. The rich ginger and

chestnut shades of the cocks and the soft buffs of the hens are very pretty. We are told that they were common in England fifty years ago. Their combs may be either single or rose. At exhibitions judges seem to favour the latter when they notice (though they rarely do so) the little creatures, but our own best and smallest birds have single combs. Their legs should decidedly be blue. Partridge Bantams were, we suspect, nearly allied to Nankins. The old Golden and Silver-spangled seem almost extinct. We remember them, and have a stuffed specimen of a hen which lived long before our own days.

In some few particulars Bantams require different treatment to most young poultry. To begin with: Though most of them when full grown are hardy birds the chickens are not so in their early days. They develop their first feathers with great rapidity, and while this growth is going on must be kept dry and tolerably warm. We always put them in coops with wooden bottoms raised off the ground. In the earlier months the coops should be under a shed, and at all times they should have little wire runs in front, over which sacks can be thrown during rain. As a rule we find Japanese Silky hens far better mothers for them than Bantams, which are too anxious and fussy and will not endure interference. Many people advise rearing Bantams in the autumn with the object of checking their growth and so keeping down their size. We cannot appreciate the wisdom of this plan; for in the first place the major part always succumb to the early winter, and furthermore in all varieties of Bantams save Sebrights and Pekins the sickles of the cocks are one of their chief ornaments. These are seldom acquired during the year by any save fairly early birds, and in all Bantams are very inferior after the first year, so that late-hatched cockerels do not generally ever possess them at all in perfection. We like to hatch Bantams in May.

Then as to feeding. It is most important not to stuff them and so increase their size; still the young chicks must be constantly fed for three weeks or so, or their strength fails. Where insects abound they will pick up support enough, but where premises are too small for this a few groats or crumbs must be frequently thrown them in their earliest days. When once fully fledged they will thrive on two meals a day. Their diet may well be more stimulating than that of the larger breeds: a little of the spiced foods which we abhor for Dorkings, Cochins, and Brahmas may be given with advantage. The development of their adult form and plumage will be hastened, and this is an advantage. There need be no trouble taken to separate the sexes as with half-grown chickens of the large breeds, only do not let your numbers increase too much for your accommodation. Bantams are the fowls for the busy, who can only spare them a few minutes of attention in the day. To such we recommend them, and are sure that a little leisure time bestowed on them will not be profitless.—C.

FEATHERED FRIENDSHIP.

AN instance of what may be justly termed bird-taming extraordinary is afforded by Mr. McIntosh in his beautiful garden at Duneevan, Otlands Park, Surrey. Always at home attending to and enjoying his garden, the owner has contributed a striking and wonderful feature of interest to his home by having domesticated birds that are usually wild, timid, and mistrustful. Two years ago we saw a Robin follow its friend and benefactor all over the garden, and so great was the intimacy existing between them that the bird would fly up, settle and nestle in its protector's beard and pick the crumbs from his mouth. What a subject for the pencil of Mr. Harrison Weir! The confiding bird it is supposed paid the penalty of its extreme docility, for it has not now been seen for a considerable time. Mr. McIntosh has, however, succeeded in securing the confidence of other birds, and although the intimacy of them and their protector is not quite so great as in the case of the Robin, yet is scarcely less remarkable because of the greater natural wildness or timidity of such birds as Chaffinches and Song Thrushes. Chaffinches, it is well known, are pert enough and will permit the near approach of man when they are provokingly engaged on a bed of newly-sown seed; but it is far from the nature of the bird to regard man as his friend. That, however, appears to be the fault of the man rather than the birds. It is new to see Chaffinches follow, not afar off, but at the distance only of a few feet, the steps of a gentleman around his garden. At one moment the birds are in a bush at his elbow, at another whirling round his head twittering their request for a crumb. Never without a supply of biscuit, their provider scatters it, and the birds peck it from the lawn near his feet. Equally familiar are the Thrushes and their friend. Those timid birds, which usually dread the approach of man, at Duneevan are as tame as chickens. Not only does the mother Thrush fetch the scattered food that is given and carry it to her young, but when the young birds are fledged she brings them to the source of supply, and feeds them in the greatest confidence close to her friend and his visitors. So thoroughly domesticated has this Thrush become, that if other birds attempt to obtain the food thrown to her she will quietly remain pecking while the interlopers are frightened away. This is the second year of Mr. McIntosh's intimate

acquaintance with this confiding bird. The goodwill existing between the owner of Duneevan and the feathered tribe affords evidence alike of the tractability of birds in a state of liberty, and especially of the great power of kindness and gentleness when those attributes are exercised perseveringly. The extraordinary tameness of the birds in question renders Mr. McIntosh's garden and grounds additionally enjoyable by the several visitors who call to inspect them.—VISITOR.

VARIETIES.

MESSRS. GOLDSBROUGH of Melbourne state in their report prepared for the March mail from Australia that owing to losses through the great drought there will be a deficiency in the year's supply of wool for export. Their estimate for the three leading colonies—Victoria, New South Wales, and South Australia—is that the total will be less by 90,000 bales than it would have been if the season had been ordinarily favourable and had given the usual increase of 7 or 8 per cent. over its predecessor. Assuming that each bale contains 100 fleeces, this shows a deficiency of 9,000,000 sheep; so that in fact, instead of shearing about 68,000,000 in the above three colonies, only 59,000,000 were mustered. The shipments from the other colonies—Queensland, Western Australia, and Tasmania—are comparatively unimportant, and do not affect the result. New Zealand will probably show a slight increase.

—THE Government of Chili has officially announced the recent discovery of large deposits of nitrate of soda and of guano in the vast desert of Atacama, which lies between the 23rd and 27th parallels of latitude, and extends almost from the coast line to the base of the Andes. The nitrate of soda is described as of great richness, and the deposits of guano will bear comparison with those of Peru both in their quality and quantity. In order to turn these sources of wealth to practical account the Government has determined to construct railroads communicating with a shipping port on the coast.

BEE MANAGEMENT.

THE following is extracted from a letter sent to Mr. Pettigrew. "Yours is a practical work, and many people will thank you for its sound information. We bought a dozen large hives, 20 inches wide by 12 deep, in September, and put two or three swarms in each of them according to your directions, fed them for about fifteen days, and wrapped them well up with old rugs, &c. We have fed them gently this spring, and to-day we have examined them and found them full of combs and bees to the bottom. We have not lost one, nor is there a weak stock amongst them. The weather is excessively cold here, and has been snowing twice to-day. If the weather become favourable we shall see the worth of large hives. Old bee-keepers here laugh at us, but we can bear this. We saved all the bees in the village from the brimstone pit last year and united them without any trouble, and have you to thank for that.

"I must tell you I have not kept bees solely for their honey-gathering properties. I have been a gardener here for forty years, and know that we are greatly indebted to the honey bee for our crops of fruit and for some good varieties of vegetables. The blossoms are impregnated by bees, and here we have raised several new broccolis—viz., Mammoth, British Queen, Emperor, Surprise, and some others not yet sent out, also some good sorts of apples. For these and many more we are indebted to the honey bee. After all has been said about the profits of bee-keeping and the properties of bees half their worth has not been told. I saw two of your large hives which stood in the midst of the town of Hull taken last September; one weighed 96 lbs., the other 35 lbs. I do not now keep wood hives, for I found if I had a dead stock it was in a wooden hive.—JOHN ELLIOTSON, *Holderness, Yorkshire.*"

ON BEE-FEEDING.

WITH bees, as with mankind, the way to the heart is through the mouth. Profit depends upon good food and good feeding. No living creature thrives, and still less does it pay, if badly or scantily fed. Food for bees, as for all animals kept for profit, must be suitable in quality and sufficient in quantity, or the bee-keeper's hopes will be certainly frustrated. Cold will not kill bees if moderate care be taken of them, for it is well known that they live and thrive in the cold parts of Russia. I have picked up a queen bee in the garden path apparently dead in a bright but cold day, I think in early February, and I have brought it round with a little care and kept it several weeks indoors, and returned it to the hive from which I had reason to believe it had escaped.

It has been suggested that honey, or honey diluted with water, is the best food for bees; it may be, but I have some doubts about it. The authors of the "*Maison Rustique*" object both to pure honey and to honey thus diluted, and they recommend in lieu of this a piece of old comb which contains some por-

tion of what is termed bee bread in it as being more substantial and more satisfying. Honey-and-water diet is of course a cheaper food, but no prudent apian practices economy in bee-keeping. If this mixture happens to get candied or touched by the frost mischief assuredly follows. A neighbour of mine, a very old bee-keeper, never gave his weak stocks any better food than a little powdered loaf sugar, which he threw into the mouth of the hive at night time. Even this little attention astonished me, fond as he was of his bees, for he maintained (and he was a shrewd man in his way and a public lecturer) that bee-feeding was a new-fangled notion utterly contrary to Nature—that, like the “flowers of the field” and the “fowls upon the mountains,” bees are dependant upon better care than ours, and therefore are better left alone. It is wonderful how old-fashioned bee-keepers differ upon this subject of food. Some weeks ago I was travelling through an out-of-the-way district in Essex, and I observed an old woman watching her bees. As she was a tenant of mine I took the liberty to ask her what she was so interested in. She replied that she was feeding her bees. Seeing saucers in front of the hives my curiosity was excited, so I asked for an explanation. She said that she had been giving her bees some tea. It seemed to me the strangest of all beverages for bees; and as I could scarcely avoid a smile she remarked that she always gave them tea, and that they took to it kindly enough and did very well upon it. The thought occurred to me, What bee-keeper has not given his bees boiled beer and sugar? Is one drink more ludicrous than the other? and if, as Sir John Lubbock showed last summer, bees are deficient in all moral qualities, it must be quite as well to keep temptation out of their way and teach them temperance if we teach them nothing else. The most common of food for bees is this mixture of sugar and beer, and there is no food which involves so much risk. Three seasons ago I lost more than twenty hives by indulging them too freely in this delicious drink, so I shall henceforth give up beer, though I have no intention to adopt tea as a substitute.

Barleysugar is always a safe and agreeable food for bees, and as its cost may be reckoned at little more than the value of the sugar it is not expensive. I took a hint some years ago for barley-sugar-making from Mr. Henry Taylor's “Bee-keeper's Manual,” which contains a good deal of useful information. To 2 lbs. of loaf sugar I add half a pint of water. These I boil for about twenty-five minutes. To ascertain whether it is boiled sufficiently drop a little of the boiling liquid on a cold plate. If it hardens quickly and becomes brittle it is boiled enough. Instead of using all water it is better to put about a fifth part of vinegar, which hastens the process without impairing the quality of the food. When sufficiently boiled pour it out gradually into a flat shallow dish previously besmeared with a little fresh butter to prevent it sticking to the platter. In a few minutes it will become sufficiently stiffened to admit of its being easily cut into strips with a pair of scissors for insertion into the mouth of the hive, or into a jar or glass for feeding at the top of the hive. It is scarcely worth while to give 1s. 6d. per pound for barleysugar when you can make it yourself for 6d. It may be well to look to the children while this manufacture is in hand, or there will be but little economy in it after all. When a considerable quantity of food is to be given in a short time the mixture I recommended in a former paper will be found to serve every purpose.—C. LILLEY.

A STEP IN ADVANCE.

ALLOW me to inform Mr. Pettigrew that the bar-framists have taken the “step in advance” as regards the enlargement of their hives by eking or nading. Last spring Mr. Abbott supplied me with some bar-frame boxes 6 inches deep, of the exact dimensions in other respects as the Woodbury hive, and thus adapted for either nadirs or ekes.

This is a step in advance of the old system of eking. The defect of that system was the very common tendency of the bees to fill the ekes and nadirs with drone comb. In the bar-frame this can be obviated by filling the frames with worker comb or wax sheets of the worker pattern. These 6-inch boxes can be used on the Stewarton system of storifying, and have this advantage over the octagon hives that all the frames are of the same size.

As a matter of experience my objection to the Stewarton system is, that the frames in the lower boxes are not accessible without the removal of the upper box or boxes. There is no system of enlarging straw hives which cannot equally and with more advantages be applied to frame hives. As a matter of fact bar-frame hives admit of greater facilities for expansion and contraction than any hive on the fixed-comb principle. And to expansion and contraction let me add extraction as another advantage which the bar-frame hive has over others, and is consequently—ANOTHER STEP IN ADVANCE.

OUR LETTER BOX.

PRESERVING EGGS (D.).—Mix 4 ozs. of glycerine with 2 ozs. of olive oil and rub the eggs with the mixture. When dry pack them in sand with their large ends downwards.

GREEN TREE FROG.—*Flora* asks for information how this animal is to be treated.

SEEDS FOR BIRDS (C. Sinclair).—Your mixture is far too varied. Canary and millet seeds in equal proportions are sufficient.

YOUNG BEES CAST OUT (Chas. Major).—As your hive is very strong in bees and the weather of late has not been favourable for honey gathering, the probability is great that the bees are short of food and have cast out some young ones in order to save themselves from starvation. In times of threatened starvation young drones are generally first sacrificed and cast out, and sometimes unhatched bee-brood is cast out in like manner. If liberal feeding does not at once prevent the bees from destroying their brood we may be certain that the brood is hurt or defective in some way, and therefore its removal from the hive is necessary. It is not an uncommon thing to find a few imperfect young bees thrown out of healthy prosperous hives, and sometimes young bees on escaping from their cells, or on being hatched, drop on to their boards and are there chilled to death. This takes place in hives not filled with comb. You say your hive has been fed liberally. If you have of late been giving it a pint of syrup daily the bees have not received more than enough for the wants of the hive during unfavourable weather, for both bees and brood consume a great deal in full hives.

COMB FOUNDATIONS (A. G.).—The sample of foundations you have sent is meant for bee-comb, not for drones; and it does not matter which end is fixed to the top of the hive or super, the bees will arrange and build the cells to dip in the right direction. The sample is a good one, and the sheets you have obtained are large enough, being 18 inches by 12. The weight of the sheets will depend on the perfection or thinness of their make, and the price will be regulated by the demand. One shilling and sixpence per sheet of 18 inches by 12 is certainly higher than was indicated in Mr. Hunter's remarks. Those who have foundations to sell should advertise them at the present time.

REMARKS.

22nd.—Fine day throughout, but cool.
23rd.—Rain in early morning, afterwards fine but dull. [the day.
24th.—Fine morning, heavy shower 2.34 P.M., and showery during the rest of
25th.—Very bright early in the morning, showery between 11 A.M. and 1 P.M.;
fine afternoon and evening.
26th.—Fair day, few sharp showers; fine evening.
27th.—Showery in morning, fine afternoon and evening.
28th.—Dull but fair morning, heavy shower at 5 P.M., light rain during the evening, and heavy showers at night.

The week on the whole has been cold and showery, with low barometer and generally unsettled weather; but occasional bright sunshine has made the radiation temperature higher than last week, though low for the time of year. All other temperatures are below last week.—G. J. SYMONS.

COVENT GARDEN MARKET.—MAY 29.

LARGE quantities of foreign goods, such as Cherries, Apricots, and Tomatoes, are now arriving from the Continent, and have been sold at low prices. The first consignments of English Pears reached us to-day.

From observations taken near London during forty-three years, the average day temperature of the week is 69.8°; and its night temperature 47.8°.

FERTILISING MELONS.

The main crop of Melons will soon be forming in many places a few remarks on setting the fruit may be acceptable to some of your readers at this time. As all Melon growers know, Melon plants produce male and female flowers. The latter are easily distinguished by having the embryo fruit attached to their base, while the former have not. The male flowers are produced first, as a rule, and very often in much greater numbers than the females. They are also often emitted from the axils of the leaves on the main stem, but the female flowers generally appear on the shoots some distance from the main stem.

When early Melons are desired the first female bloom that opens should be fertilised, but when there is no particular hurry none of the blooms should be touched until about half a dozen with embryo fruit at their base are open, then the whole of them should be fertilised together. The fruit then swells equally; but the notion that when one Melon is formed it is difficult to secure more on the same plant a week or two afterwards is not always correct. We have set fruit on the same plant some weeks between each other, but the last-formed fruits do not always swell so perfectly as the first.

The practical operation of fertilising consists in pulling off the male bloom, carefully removing all the petals, and rubbing the anthers gently in the centre of the fruit-bearing flower. It is the pollen that is conveyed from one flower to another that causes the fruit to set. Fertilising should never be done unless both flowers are fully open. It is not of much importance when it is done. We do ours from daylight until dark with perfect success. Syringing should be discontinued for a few days when the fruit is just beginning to form, but paths and other surfaces of the house may be watered to keep the atmosphere moist. Some say that if the roots are watered from the time the fruit is newly formed until it is the size of an egg it will become yellow and decay; according to our practice this is not correct, as we water the plants regularly with the fruit at all sizes, and the result is always more beneficial than injurious.

Where there are only a few Melon plants grown sure-fruited sorts should only be cultivated. In this respect there is great difference in some sorts; some plants grow luxuriantly, but produce no female blooms; others bear them in profusion. One of the shiest fruiting sorts we have this year is Carter's new Pine Cream. We have it in three different batches, in each of which it has grown satisfactorily, but as yet not one of them has produced a single female flower; others growing on each side have fruit as large as swans' eggs. Why it is sterile I cannot say; perhaps some of your readers will state their experience with it. We find Sutton's Royal Horticultural Prize produce female flowers much freer than Sutton's Hero of Bath. Eastnor Castle is a very free fruiter, and so is Reid's Hybrid. Little Heath is not equal to either of these in

producing female flowers, although it does better in a cool house or frame.

No Melon should be left to fertilise itself, although many fruits do set and swell after a fashion without any assistance, but such fruits seldom grow so quickly or become so large as those which have been properly fertilised. The first female bloom that opened on one of our Khiva Melon plants this year set itself. Ten days afterwards another fruit was set on the same plant by fertilising, and the latter is now as large again as the former, which shows that, although Melons may set themselves, they have not the advantages of 'properly fertilised fruits.'—A KITCHEN GARDENER.

THE ORCHARDS OF HEREFORD AND WORCESTER.

[The following excellent paper was contributed to the Annual May Conference of the Vegetarian Society by Mr. Baron de Webster, of Newland Court, Great Malvern.]

THOUGH differing in many other respects, these two contiguous counties are mostly reckoned as one as regards their fruit cultivation. Parts of Gloucestershire, Shropshire, and Warwickshire, which adjoin, are also included in this tract of orcharding.

Nurserymen are fond of stating in their catalogues that Apples do well in any soil. No doubt by such assertions they gain more orders, but it is a question whether the country has many more Apples. Some are bold enough to add that a deep friable loam suits them best. No doubt of it; and most other things as well. It is quite certain, however, that the most important condition of the soil for the Apple tree is depth, and this, in the neighbourhood above referred to, it thoroughly enjoys. The formation of the country, too, affords numberless sheltered hills and sunny slopes where fruit trees luxuriate as if in walled gardens.

There is no doubt that Worcestershire was enclosed and highly farmed at a very early period, and the cultivation of Apples and Pears must have been energetically carried on from the first. Herefordshire produces, perhaps, the best Apples, but very few Pears. The latter fruit gives one the best idea of the antiquity of this sort of cultivation. The remaining trees in the celebrated Barland Perry Orchard at Monksfield Farm, near Malvern, are stated by one writer to be six hundred years old. This is probably an exaggeration, but there are, doubtless, many trees scattered over a large area that must be several hundred years old. An Apple tree would hardly be of any use to the owner after a hundred years, but the Pears above referred to are still, many of them, most valuable. The ground, however, seems tired of them—and no wonder—and the grafts taken from them do no good.

Few Worcestershire homesteads do not possess a few of the Early Jennet trees, which still bear bountifully though of an enormous age. This and other descriptions of the earliest Pears ripen about the 1st of August, and in a good year help the farmer very much with his labour bill, so heavy at that time of year. The fruit is shaken down by boys, who climb into the trees with long hooked poles, and picked up by women underneath. Sacks and cider cloths are spread underneath to break the fall of the fruit. These

are the Pears that are so constantly seen in the early autumn hawked about the streets.

Hop and fruit cultivation often go hand in hand, the former demanding even more imperatively a deep soil. In the famous Team valley—one of the richest spots in England—the ground will apparently grow Hops for ever, the plantations being replenished as needed, and well cultivated. On the uplands, however, it is found necessary to change the Hop ground every twelve or fourteen years. The effect of Hop-growing on the soil, contrary to what one would suppose, is to render it almost as fertile for a renewal of general cropping as virgin soil. An old writer, indeed, drily remarks that “the greatest profit in Hop-growing is the breaking-up of the soil afterwards.” Up to the present time, whenever Hops were planted, an orchard was planted at the same time, as an economy of labour and ground. By the time the trees began to be prejudicial to the Hops it was time to remove the latter altogether. Of course the field remained arable, but that used to be thought no hindrance to the orchard; or rather, the orchard was thought no hindrance to the arable field. When it is considered how much finer the trees grow on an arable field, and that they are thus nearly always out of the way of cattle and horses, it will be seen that the disadvantages are compensated for. These are the spoiling of corn crops by the sun being kept from them (a trifling loss if the trees are not planted too closely), and the difficulty of cleaning the field when encumbered with trees. No difficulty exists as to ploughing, though a slight extra expense is entailed by the necessity of having three men or boys attending to the horses when the tree rows are being ploughed out, and also of having the ground just round the trunks dug with the spade. This is well done by any labourer for 1d. a tree.

When orchards are planted in grass land it is much better to have the young trees dug round for several years. They require to be fenced in on grass land with great care and expense, and at the time of the ripe fruit everything must be kept out of the field. It is far better, when planting an orchard on the green, to stock it for the first few years with nothing but sheep and young cattle. Horses and full-grown cattle will knock over any fencing, unless made so strong as almost to interfere with the growth of the trees.

The best and cheapest fencing for young trees is of this description: Plant firmly in the ground, in the shape of a triangle, three stout hop-poles (about as thick as a man's arm), and cut them off to about 4 or 5 feet high. They should stand about 1½ foot from the stock and lean outwards. To these nail wire netting as high as sheep can reach. You are then safe from sheep and game. If calves and young cattle are to be in the field, protect the wire netting again well with bushes fastened round with wire. If cattle and horses must come in, however, there is nothing for it but the old-fashioned heavy wooden cribs, which, besides being very cumbersome and expensive, are also detrimental to the prosperity of the tree. Their great posts make holes for the wet to accumulate and lodge in during the winter, and cracks to let the drought through in summer. Of course, in pruning, the object is to keep the branches growing outwards from a stem about 5 feet high.

Some farmers, who are convinced of the profits of growing fruit, are so particular on these points that they get slightly eccentric, to say the least, and discharge their men for the slightest infringement of their rules. An Apple tree can hardly become very profitable under fifteen years' growth at least, and it certainly is most aggravating to have a tree, or perhaps an orchard full, seriously damaged by purely avoidable causes after perhaps a most careful watch has been kept on them for ten or twelve years. After an orchard is once well started the only expense connected with it is the pruning, and that is about covered by the sale of the “brash.” Apple trees in Worcestershire often attain the size of an ordinary Oak, and a tree of a good sort will bear twenty-five bushels of Apples. One Pear tree will often make as much as two hundred gallons of perry.

It is very dangerous to lay down to grass an orchard that has hitherto been in tillage. It often causes all the trees to die. The ordinary one-year's course of seeds does not seem to hurt them, but a two-year's ley undoubtedly does. The decrease in the extent of orcharding and the inattention to fruit cultivation is very sad to see, and it will not be amiss for us to look into the reasons for it.

1. First of all we have the enormous and grossly unfair profits taken by the “middleman.” A pot (five pecks or 80 lbs.)

of fruit bought from a farmer for, say, 10s. is not sold to the public under 20s. or 25s. The usual system is for the farmer to take his fruit to one of the merchants in Worcester, who sells it for him on commission, in reality to middlemen in large towns; so (at least so he is told) the merchant, in paying the farmer, always professes to be getting only 6d. or so per pot out of the matter.

At the same time they carry on the business in other ways—buying fruit in large quantities on the trees or after being picked and keeping it themselves as a speculation. A large farmer with much business to transact cannot be always personally looking after the sale of every load of fruit, and most of them usually sell it in this way. All that the farmer does not want to keep for the winter he sends in as fast as it is picked, and notes the quantity in a book which is taken to the merchant, who signs it and adds the price he means to give for it, or sometimes the price he will give for the previous lot, this being still uncertain. The farmer can, if he is at any time dissatisfied, close up accounts; or, if he goes on all the year, can draw money as he wants it, sometimes drawing more than is due. At Christmas the book will be squared for the season. Sometimes the fruit is sold by auction on the trees, orchard by orchard. In the former way, of course, each individual lot of fruit is quite at the mercy of the merchant, and the farmer loses the full advantage of sudden and spasmodic rises in the market. On the other hand, he never has his fruit refused in a great flush. It is the profit made after the fruit has left the merchant and before it reaches the public that is so unfair. For instance, in one abundant year, when a pot of good fruit did not fetch more than 2s. in Worcester, enough to make an apple tart cost 1s. 8d. at Malvern. A commodious fruit market has been built at Worcester, but it does not seem to work in any beneficial way to the large growers. Farmers give up the business in disgust at the unfairly low prices they get for their fruit.

(To be continued.)

DOUBLE WALLFLOWERS.

It is gratifying to observe that this enjoyable old flower is not only not entirely neglected, but, on the contrary, is deemed worthy of having its merits recognised in contemporary garden literature. I allude now to single as well as double varieties. Since spring gardening has become in a measure fashionable Wallflowers have been grown in greater quantities than ever they have been grown before. No system of summer bedding, however popular it may be, will ever drive these homely old flowers from our gardens. Though not indigenous to England they have been with us for three centuries and have become naturalised, and wherever early and fragrant flowers are cherished there Wallflowers will be cultivated. So accommodating are the plants that I thought they would grow anywhere, but I am surprised to find by the account of Victoria Park on p. 373 that they will not succeed in the London parks. I am afraid those who, like myself, have practised wholly in the pure air of country districts do not, perhaps, fully appreciate our advantages. Certainly I should not be happy in gardening where I could not grow Wallflowers. I really regret that the Londoners cannot enjoy these flowers in their parks. They cannot, however, do without them, for I have seen waggonsloads piled up high like loads of hay, formed of crimson and bright yellow bunches of Wallflowers on their way to Covent Garden Market. I was glad to read, too, in your report of the Newcastle Spring Show that these common flowers were well grown in pots, exhibited and honoured. I have seen them flowered in pots in more than one private garden, and no plants flowering at the same time were more generally admired. Single Wallflowers are chiefly grown; it is these that have increased in numbers so considerably of late years. Double and semi-double varieties are not, however, entirely forgotten, but have found a friend in “W. J. M., Clonmel.”

As your correspondent truly states the semi-double varieties are raised from seed, and very good some of the German varieties are; but the truth must be told that others of them are very bad. The only safe way of perpetuating the really good semi-double varieties is by cuttings; while the real doubles—the old double red (Blood Wallflower) and the golden yellow cannot be increased in any other way. “W. J. M.” describes a mode of striking the cuttings which is for amateurs who have no heated frames, and he also gives sound cultural advice generally.

I have grown double Wallflowers for many years both for conservatory and garden decoration, and I adopt a speedier plan of striking cuttings than that described in the article referred to. I insert them as early as they can be obtained in pots of sandy soil and place them in heat, indeed giving the same treatment as cuttings of tender softwooded plants. In a week the cuttings emit roots and are then removed to a cool frame, and eventually to the open air. They are divided and planted out in June, and in the autumn are fine, bushy, flowering plants. I find few plants more easily raised and more valuable than double yellow Wallflowers for conservatory decoration in spring.—A. N. G.

DUCKS VERSUS SLUGS.

So many people having tried to write down the use of ducks in a garden I will attempt to state plainly all I know for and against them, and your readers can then judge for themselves on which side the balance inclines.

Last year three broods were hatched, and as I was a little timid the first of these had only a limited run and were shut up at night. The next brood had the whole run of the walled-in kitchen garden, about five acres, being only shut up at night till they were about a fortnight old, and continued to have it all to themselves till the third lot began to run about a good distance, when, not being likely to agree very well, the elder family were turned outside the garden walls where they had free access to two or three acres of other garden ground, an orchard and small ponds, and were allowed to roost where they liked. In from seven to ten weeks from hatching they were all fit for the spit, the Aylesbury being the first and best. It is right, however, to say that I have had no other true stock, the rest being cross-breeds. This year so far I have had three broods, but one mother proved a cannibal and only three of her progeny were saved; these were kindly taken under the wing of a foster-mother which already had eleven a fortnight old, and all have done well.

Now as to the manner of feeding, for herein lies the secret of making them useful, and I think it will be easily understood how it is that the evidence concerning them is so conflicting. Can it be wondered at by any reasonable person that if you feed them up with as much barleymeal, maize, or other heating food as they will eat, that they should want some green vegetable food to counteract the effects of it? But reverse the order of things: Give them plenty of fresh vegetable food—nothing suits better than boiled potatoes for the staple, with just a taste of meal mixed with it—when the weather is cold or the ducks are small, and in addition to this let them continually have green food in the water; they enjoy it so much better there that they will scarcely then be likely to touch it elsewhere. Sometimes, however, they do take to picking and stealing, and it is then difficult to reform them; but even when they do take to helping themselves, say to a row of Lettuces (they are fond of well-blanching salad) they do not generally spoil much but clear the row to the root if it is all tender as far as they go, and I believe their depredations are always brought about in the first place by improper feeding or neglect.

Well, now, what good do they do? As soon as ever day breaks they start off and work over a whole patch of Cabbages, Peas, or other crops in which slugs abound in a thorough workmanlike manner. I have seen them taking a breadth in perfect regularity, one on each side of a row, working it to the end and then turning back on other rows, picking up more slugs in half an hour than fifty men could possibly do. Besides it would be done before it was sufficiently light for men to see them, and actually at this time of year two or three hours before the workmen come. They like worms best, then soft slugs, but in the morning they do not object to the little hard black ones, such as I think no small bird will eat; and I am sorry to add that when they are hungry they do not even spare our good friend the worm-eating slug (*Testacella helioides*) or a good plump toad. This probably arises from jealousy and the fear of a slug and worm famine, but there is no immediate danger in that way. However, slugs are certainly not so plentiful by a long way as they were a few years ago. Then on mild mornings our kitchen garden walks were almost covered with the detestable little black things, and five or six men were often employed for two hours picking them up; now I am happy to say this is not necessary.

Someone suggested a few weeks ago shaking a lime bag round the garden. But these little hardy gentlemen are not

to be frightened by a lime bag; if their outer skin gets too much scorched they simply slip it off and start afresh. If you can catch them again with another hot dose before they get hard you may have a chance, but otherwise they are only slightly inconvenienced.—WM. TAYLOR.

P.S.—Some four or five years ago Longleat had a very unwelcome visitor in the shape of the American Water Weed, which rapidly overran most of the ponds, including the large lake below the mansion known as the Half-mile Pond. So thick had the weed grown that it was difficult to get a boat across or to pull a fish through when one was hooked. Decaying matter of all kinds was prevented floating away, for the weed was quite up to the surface and in some places above it. Matters began to assume a very serious aspect, for at times the decaying matter began to emit an unpleasant smell; and some began to be afraid that the beautiful lake, one of the main features of this fine park, would on sanitary grounds have to be dried up. Some young swans were procured, pinioned, and turned loose, and although it was believed that they would eat some of the weed, no one dreamed of a few birds making any visible improvement on such a large area; but they have increased now to about two dozen, and the surface of the water is perfectly clear for a foot or 18 inches down. They are not fed in any way, and their natural food, which was at one time so easy to procure, now involves a considerable amount of labour; so there is an addition to the charms of this place by the presence of the graceful swans, and the dreaded weed is not so dreadful after all.

HINTS ON LANDSCAPE GARDENING.—No. 5.

VILLA GARDENS.

EVERGREEN trees play an important part in villa gardens in the formation of screens for shelter as well as for privacy. Conifers are prime favourites in this section, and deservedly so. They do not, however, answer well in the smoke-laden atmosphere of the suburbs of large towns; yet even there they live and grow for some years, and would probably present a more flourishing aspect under the advantage of frequent washings of clean water thrown forcibly among the fine dense foliage by means of a syringe or garden engine. Here are a few possessing distinct characteristics and which have proved to be worthy of a place in the most select assortment. First comes *Abies canadensis*, beautiful as a shrub, still more so as a tree, and yet I could not indicate half a dozen gardens in which I have met with really fine examples of it. The noble specimens growing near the Screw Fountain at Alton Towers in Staffordshire are worthy of a special pilgrimage. Plant also that other fine Hemlock Spruce from Oregon, *Abies Albertiana*, of slender tapering growth, thin-branched, yet elegant; *Picea Nordmanniana*, best of all the Silver Firs; *Picea nobilis*, valuable for the bright glaucous tint of its foliage; *Pinus insignis*, so cheerful and warm-looking in winter with its dense clothing of lively green needles; *Cupressus Lawsoniana erecta viridis*, of a peculiar and pleasing shade of green, and forming a much more handsome tree than the original Lawson's Cypress, which, however, is quite worthy of a place; *Thuja borealis*, a dense dark green cone with pendant tipped branches, an especial favourite; as are also *Cedrus Deodara* and *C. Libani*. *Juniperus virginiana* forms a handsome, dense, tapering cone, growing freely; but it must be protected from the attacks of rabbits, which are very fond of its tender shoots, quite spoiling the plants when they are young. *Cupressus macrocarpa* from California is another fast-growing Conifer, dense, tapering, beautiful and distinct; and the elegant jointed Cypress, *Arthrotaxis selaginoides*, from Tasmania must certainly have a place. *Cryptomeria elegans* from Japan brings my selection up to a dozen of the very choicest Conifers taken from the two or three hundred with which we are now familiar in this country.

For every purpose to which an evergreen shrub or tree can be applied and for every situation, the common green Holly (*Ilex aquifolia*) attaining to a height of fully 30 feet in good soil, is, I think, the best, none other having the advantage of it except in height. Poor soil somewhat stunts its growth, but does not affect its health; shade and drip have no power to harm it, and it absolutely revels in bleak exposed situations where other trees can hardly exist. If you want a roadside hedge or screen, what can equal its dense growth armed at all points, the prickly foliage bidding defiance to would-be intruders? If you want a lawn clump it will furnish you with symmetrical specimens always clothed with handsome, glossy,

deep-green foliage, thick set yet wonderfully light and sprightly in effect, the play of light and shade among it being equally wonderful, every leaf partaking of it and contributing its own peculiar effect. The *Arbutus*, though not useful for so many purposes as the Holly, forms a worthy associate for it in lawn clumps. The kind most grown is the European species *Unedo*, always ornamental in early winter with its clusters of white flowers, and in sheltered situations is often laden at the same time with large crimson pendant berries. Its scarlet-flowered variety *Croomei* is worthy of a place, as also is *A. Rollissoni* for its large, long, white, waxy flower clusters. In the southern counties the scarlet-fruited evergreen *Benthamia fragifera* would make the third choice tree for our clump. It equals, and will I think eventually exceed, the Holly in height under the most favourable circumstances. Its growth is erect, and as the tree gains size it becomes so symmetrical as to be always ornamental. *Embothrium coccineum* is another choice tree for the sunny south. It is an evergreen that for brilliancy when in bloom surpasses all others yet in cultivation. The finest specimen of it in this country is thoroughly established in the garden of Mr. George Williams at Scorrier in the northern mining district of Cornwall. It is about 30 feet high, and its scarlet flowers are in full beauty in July and August. When I saw it at the end of last August enough flowers were still left to convey some faint idea of its gorgeous appearance when in full bloom. *Cerasus lusitanica*, the Portuguese Laurel, an old and well-tryed favourite, with its imposing mass of rich green foliage, worthily holds its own in our clump, as does *Laurus nobilis*, the aromatic Bay, and to enliven it with a rich mass of deep yellow we will introduce a Golden Queen Holly. *Quercus Suber*, the Cork Tree, ought not to be left out, for it is very ornamental, and does not often exceed a height of 20 to 30 feet in this country.

It is of course unnecessary that any one clump should include the whole of these trees, for every one of them under favourable circumstances becomes such fine specimens as to prove as effective in isolated positions as in clumps. Choose one or all of them according to your requirements, and I may safely venture to promise you will not be disappointed. It may be thought that the *Ilex* should be included in such a list, but the omission was intentional, its great height, size, and hardness rendering it more suitable for the formation of sheltering belts and screens.

Among evergreen shrubs I am desirous first of all to strongly recommend *Quercus glabra*, the Japanese Oak, to general notice. It forms a handsome shrub, somewhat spreading, and well clothed with stout, smooth, Laurel-like foliage. The finest specimen I have met with is in Messrs. Woods' nursery, and, speaking from memory, it is some 8 feet in height and as much in diameter. Of other shrubs let *Rhododendrons* predominate. Add to and mingle with them as you have space such choice and useful shrubs as *Escallonia macrantha* with glossy deep green foliage and bright pink flowers in summer and autumn; *Ligustrum japonicum*, that has been well described as "a very beautiful shrub, with leaves like an *Otaheite* Orange, and flowers like the *White Persian Lilac*;" *Mahonia aquifolia*, very hardy, but requiring good soil to bring it to full perfection—it is quite worthy of our best pains and care, as also are its allies the *Berberries*, of which *Darwinii*, so bright in April with its dense clusters of rich orange-yellow flowers, is a general favourite; *dulcis*, *stenophylla*, and *Wallichiana* are also good. *Desfontainea spinosa* with its Holly-like foliage and long tubular scarlet and yellow flowers is a great beauty, which cannot, however, be left out to winter in northern gardens. In the south it answers very well, and its flowers are in perfection in August and September. The finest examples I have met with established in the open air have not exceeded a height of 6 to 7 feet. Such large shrubs are by no means plentiful, nor in point of fact are plants of any size. I have seen a few clumps or rather beds of it composed of plants some 2 to 3 feet in height, that were very attractive from the uncommon and gay appearance of the flowers. For a small garden where choice shrubs are cherished it is admirably adapted for the front of borders or clumps. Every garden should also have at least one example of double Gorse, nobody having seen only the wild single variety can form a just conception of its beauty. For some weeks in spring it becomes one dense mass of deep golden yellow bloom, which exhales a perfume so powerful as literally to cloy the air with its sweetness. *Garrya elliptica* is another of our best shrubs, much neglected simply through ignorance of its value, and yet it has been in this country fifty years. It is very hardy and robust,

and is very ornamental in winter when its handsome catkins are produced. A little care in pruning is requisite to develop their full beauty, and they are then nearly a foot in length; unpruned trees, on the contrary, bear a profusion of catkins not longer than 3 or 4 inches. *Raphiolepis ovata* with its stout glossy foliage and spikes of white flowers, just now in full beauty, is also worthy of a prominent position. Then there are the *Pernettyas*, so neat and pretty with their white Heath-like flowers and pink berries; the bolder and more effective *Skimmias*, of which I would call especial attention to *Skimmia oblata*, of more vigorous growth than *S. japonica*, and with large brilliant scarlet berries; the striking *Cotoneaster Simmonsii* growing to a height of 8 feet and laden with clusters of gay berries in the early winter months; *Cistus ladaniferus*, so lovely when in flower; and the not so well known *C. roseus*, forming almost as large a bush as *ladaniferus*, and even more valuable for the longer duration of its large rosy-pink flowers, which are just now beginning to open on some plants which I raised from seed picked from wild plants near Nice. *C. formosus*, with its equally large spotted yellow flowers, also makes a pretty bush and is equally worthy of a place.

To enumerate the more common shrubs is unnecessary, but those known as American shrubs are much too important to be dismissed thus summarily, and later on a special paper must be devoted to them. The arrangement of shrubs and trees will also be treated of in due course.—EDWARD LUCKHURST.

REVIEW.

Home Culture of the Water-Cress. By SHIRLEY HIBBERD. London: E. W. Allen, 11, Ave Maria Lane, Paternoster Row.

THE author in his closing lines describes this little brochure of fifty pages as a "trifle, the inditing of which has been more of a recreation than labour." A work written in that spirit, and especially by Mr. Hibberd, is sure to be entertaining; the "trifle" in question is that and more—it is instructive. It is written in the author's free, jaunty, discursive style. The subject is certainly not a "dry" one, but it is not everyone who could have connected it so adroitly with ancient philosophers and modern poets—even as ancient as Homer and Virgil, even as modern as the author himself, who winds up with a song for the "pretty Water-cress girl."

About half of the essay is practical, and details the culture of Water-cress in pots, pans, troughs, frames, garden, and streamlet, with the view of its being produced all the year round fresh and untainted with sewage or any other impurity. Varieties of Cress and their merits are discussed; "a bit of botany" is provided, wherein is told what everybody is apparently not cognisant of, that the so-called *Nasturtium* of our gardens is not a *Nasturtium* at all, but a *Tropaeolum*. There are only four true British *Nasturtiums*—namely, the Water-cress (*Nasturtium officinale*), *N. sylvestre*, *N. palustre*, and *N. amphibium*. Several pages of "gossip" are incorporated, much of which will be new to the reader and all readable, for who besides our author would have connected Water-cresses with cannibalism? but he manages it in this way. Alluding to the early period when men began to eat Water-cress, it is remarked that they "must have been known and appreciated in those early days 'when wild in woods the noble savage ran,' and doubtless garnished the luncheon table of the palæolithic warrior who had caught and cooked a sinful brother who well deserved to become what the Fijians call 'boko.'"

Although hundreds of tons of Water-cresses are sold in the metropolis annually, we are told that the "cultivation of the Water-cress is quite a modern idea. The old English herbalists knew the plant and gloried in its virtues, but never dreamt there was money in it. In Parkinson's 'Theater' the plant is correctly though very briefly described, but as a wilding only. In the 'Paradisus' there is no mention of it, for the sufficient reason that it was not known as a garden plant in the time of Parkinson, nor for many years subsequently. The authorities all agree that it was first grown at Erfurt 'about the middle of the sixteenth century,' and the very distinctive character of the Erfurt variety ('Erfurt Sweet' or 'Erfurt Green'), which differs immensely from all the English varieties, suggests that it is, as a variety, the result of special influences long continued. Whether Nicholas Meissner, who is honourably remembered as the founder of Water-cress culture at Erfurt, began with this variety, finding it ready to his hand, or whether he made it, none can tell; but it is so distinct that it might with propriety be associated with his name as Meissner's Cress.

The still-noted water of Springhead, Northfleet, was the first centre of the industry in this country (so far as we have authentic records to guide us), and the beginning of the cultivation there only takes us back to 1808, when Mr. Bradbury took it in hand and established a trade in supplying the London markets."

We will now refer to the practical nature of the essay, which describes the mode of culture originated by Mr. Hibberd, and which has deservedly met with a large share of public favour. We have seen the pans of Cress as cultivated by the author, and have admired them; we can also testify to the delicacy and general excellence of the produce. The following extract and illustration will make the matter clear to those who are still unacquainted with this certain and simple mode of culture:—

"It is such an easy matter to grow the very finest Water-cresses, that a brief lesson will enable the reader, who at this moment, perhaps, knows nothing of the business, to make a good beginning and quickly discern the value of the ampli-

fications that follow. Although any common flower pot of any size or shape will answer the purpose, and the commonest soil that will grow a fairly good Cabbage will serve to fill it, yet a better mode of procedure is to employ common red ware seed pans 15 inches wide and 4 to 9 inches deep. This size affords room for a good body of soil, which is needed for a quick growth of tender Cresses, and they are not too large to be moved about conveniently. If the pans are shallow (say 4 inches deep) lay over the hole or holes in the bottom some flat oyster shells, and then fill with rich loam, such as would be used in the cultivation of Balsams or Fuchsias. A good compost may be made by mixing mellow loam with one-third its bulk of rotten hotbed manure, and a little rough grit, such as the sand sifted from sweepings of a gravel path, may be added. Press the soil rather firmly into the pans and pile it up into a convex surface like a pie, putting a little fine stuff on the top of it, and it is ready for planting. But if deep pans are employed (say 9 inches deep) put in a bottom of flat oyster shells as before, then some lumps of broken brick, or

Fig. 65.—WATER-CRESS IN PAN

chalk, or old mortar, to a depth of 3 inches, and fill up with rich soil and finish off pie fashion, making the work look neat.

"In this case, and in every case, small cuttings taken from the tops of fresh Cresses are to be preferred, and they should average an inch in length or less. Dib them in with a bit of stick or the finger, press them firm, and let them stand evenly from the centre to the edge about 3 inches apart. Then place the pans in water pans of suitable size, into which pour an inch depth of water, and stow all away in a frame or under the stage of a greenhouse, and water overhead twice a day at least, and oftener if convenient. If not distressed by sunshine or wind they will be well rooted in the course of three days, and the question will arise, What shall we do with them?

"Supposing we are in the month of May, they may be put out of doors in the full sun and have a depth of 2 inches of water, or, if the pans are deep, 3 or 4 inches, and they will really want no more attention, but it will always pay to water them overhead once a day, for quick growing produces the best sample."

For further particulars read the book.

DESTROYING SLUGS AND GRUBS.

SLUGS and other predatory vermin have been and still are unusually abundant, doing much damage to vegetable and other crops—indeed in some localities, particularly in the north, cereal crops are very yellow and patchy owing to the ravages

of slugs and grubs. In gardens these pests are more effectively combated than in fields, but the weapon employed must be certain and speedy. It is no use looking on, prompt means must be at once instituted. Some have great faith in birds (none more than we), but they for the most part are fonder of worms than slugs. Ducks, gulls, and fowls devour immense quantities; they also eat some vegetables. The lapwing or peewit and tern, on the other hand, do not eat vegetables, but subsist entirely upon the gardener's most assiduous enemies. We always have some of the former in the walled gardens, but they only require a certain quantity of food, hence the slugs and grubs are in excess, therefore we have to adopt such other remedies as experience has shown to be efficacious. Quicklime dusted over the plants late in the evening or early morning destroys all the slugs it falls upon, but it is necessary to repeat it, as when the lime becomes wet it is practically innocuous to the pests; besides, many will have been hatched or were beneath the surface when the lime was applied. Soot is also very much disliked by slugs, the plants being dusted therewith and a circle drawn around them will mostly save them from the slugs' attacks; it must be repeated from time to time, and is very valuable as a manure. Lime, however, is the best. Persistent dustings will assuredly free the ground of slugs sufficiently for all practical purposes. Lime, however, cannot always be used, especially in flower gardens, in which case baits may be laid of fresh brewers' grains, little heaps laid here and there about the borders near to the plants infested, and after dark a lantern

and a vessel containing salt will enable those that do not like picking up the slugs to do so, putting them into the vessel containing the salt and shaking up occasionally.

Grubs are worse to deal with than slugs. They hide in the ground and have tougher skins. An agent that dissolves readily, or that may be applied in liquid form to ensure certain and early action, is most suitable. Salt is usefully applied at the rate of twenty bushels per acre in case of ambury in Brassicas and finger-and-toes in Turnips. It should be applied at the time of sowing the seed or shortly afterwards, as when the plants are large the salt is of very little use then, as the maggot is safely embedded in the root portion of the plant. Nitrate of soda is more powerful than salt, and may be applied in liquid form—1 lb. to twelve gallons of water, which is sufficient for a rod (30½ square yards); or that quantity applied evenly to that extent of ground prior to putting in the crop or soon afterwards, for it is injurious if resting on the foliage of plants.

Paraffin is certain destruction to every kind of garden pest—everything it comes into contact with it kills, not excepting mealy bug and scale in plant stoves down to grub in Onions. Being an oil, its gravity is less than water, and it floats on the surface, and is difficult to mix with water; however, by keeping stirred, or, better, forced into the water with a syringe, one squirt into the watering pot and alternate ones upon the plants, it may be kept tolerably well mixed. It is a sufficient application to thoroughly wet the plants, and in doing so the surface soil also will be made wet. No more must be attempted, or the remedy is worse than the disease. A wineglassful is a proper quantity to four gallons of water. The quantity must not be exceeded, nor must it be applied other than well mixed with the water. Neither Onion nor Carrot maggots, nor yet Celery fly, can endure it, nor can caterpillars withstand its effects; it also drives away ants, and wasps die if it be poured into their nests.—A.

ROYAL HORTICULTURAL SOCIETY.

JUNE 4TH.

AFTER the extensive and prolonged display of last week it was not surprising to find the meeting on this occasion a small one. Both the objects exhibited and the number of horticulturists were alike limited, yet some interesting plants were submitted to the Committee, and several certificates were awarded. Fruit was represented by a few Melons and Strawberries, and vegetables by Asparagus and Lettuce.

FRUIT COMMITTEE.—H. Webb, Esq., V.P., in the chair. Mr. Allen, gardener to Lord Suffield, Gunton Park, sent a very fine dish of Asparagus grown on the French system. The lower portion of the stem was blanched to the extent of 8 inches, the tips to the extent of 3 inches being green. A cultural commendation was awarded. Mr. J. Davidson, gardener to Mrs. Marson, Highfield Park, Hants, exhibited very tall examples of Suttons' Superb White Cos Lettuce, which were passed by the Committee. Mr. J. Manderson, Ottershaw Park, Chertsey, sent a seedling Melon, but it did not merit any award. Mr. Atkins, gardener to Col. Loyd Lindsay, Lockinge Park, Wantage, sent some large and fine-looking Melons, but they were not considered superior to others in cultivation. Messrs. Paul & Son, Old Nurseries, Chesham, sent Strawberry Pauline, but it was coarse and deficient in flavour. Mr. W. Thomson, Auchinraith, Blantyre, sent examples of a seedling Rhubarb, which was no improvement on others in cultivation. Messrs. Blake & McKenzie exhibited Tebbes' Universal Travelling Pot (figured on page 171, vol. xxxiii.), which was highly commended by the Committee. Tebbes' metallic card labels were also exhibited; they are simple, economical, and durable. Mr. Elliott exhibited his "Summer Cloud" for shading. It breaks the rays of the sun without seriously obstructing the light, and is a suitable application for glass where slight shade is required for the plants beneath. Amies' manure was exhibited, together with photographs of some remarkable crops of Cucumbers grown by Mr. Cooling of Derby with the aid of this manure.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. James Veitch & Sons exhibited a small and very choice group of plants. First-class certificates were awarded for *Platycerium Hillii*, one of the most stately and distinct of the Stag's-horn Ferns, a figure of which was given on page 395; for *Xeronema Moorei*, a striking plant resembling an Irid in its growth and foliage. The flower spike is nearly 8 feet long, and terminates in a brush-like head composed of a mass of scarlet stamens. It was the last of the late Mr. J. G. Veitch's introductions from New Caledonia. Also for *Adiantum cyclosorum*, a slender-growing Fern of great elegance. The fronds somewhat resemble those of *A. concinnum* latum, but are more spreading and graceful; and the pinnae, which are thinly arranged, are faintly suffused with pink. Messrs. Veitch also exhibited the fine *Hemanthus Kalbreyeri*, with a head 8 inches in diameter of brilliant flowers; the bright yellow and very striking *Ismene Amacais integræ*, the cup exceeding 2 inches in diameter, and having five radiating stripes of reddish brown in its

interior; also *Aërides Domitii*, the result of a cross between *A. affine* and *A. Fieldingi*, very fine; *Lilium concolor luteum*, the plant being 6 inches high and terminated in a large yellow flower; *Croton Hanburyanus*, the leaves being 2 inches broad and a foot long, the prevailing colours being brilliant yellow and bright green; it is one of the most effective of the family to which it belongs; the floriferous and highly attractive *Rhododendron Crown Princess of Germany*, which was so greatly admired last week by their Imperial Highnesses; and a splendid pan of *Nertera depressa*.

Mr. B. S. Williams exhibited *Phoenix canariense*, a dwarf and slender-growing Palm with narrow glossy leaflets and very elegant; *Asplenium horridum*, with erect and bold-looking fronds, rachis brown and woolly; *Eranthemum variabile*, small plants, much coloured after the manner of *Alternanthera amœna*; *Panax elegantissimum*, a very suitable plant for table decoration, the foliage is finely cut and gracefully recurved; and two Orchids—*Epidendrum trachychilum*, with cream-coloured sepals and white-mottled violet, very fragrant, and *Maxillaria grandiflora*, the flowers being 1½ inch in diameter and of great substance; the sepals and petals are flesh white, and labellum white, brown, and yellow. It will evidently continue long in beauty, and is very fragrant.

Mr. Green, gardener to Sir G. Macleay, Bart., Bletchingley, sent a singular assemblage of plants and flowers, consisting of *Aristolochia orithocephala*, richly marbled and spotted; *Gardenia Stanleyana*, a striking trumpet-shaped flower, which often requires a year to expand after the flower buds are visible; *Nidularium Scheremetiana*, a Tillandsia-like plant with violet flowers; *Posoqueria longiflora*, flowers and tube white, the latter 6 inches in length, the flower bearing some resemblance to a very large Bouvardia; *Carolinea insignis*, a West Indian shrub—the foliage is a foot in length and 4 inches in width, and the flower, measuring from the tips of the four sepals, was nearly a foot in diameter. The interior of the sepals is white, the centre being composed of long white stamens tipped with scarlet, somewhat resembling a Cactus. It is a remarkable flower and seldom seen)—*Marica gracilis*, a singular Irid; *Lathyrus Drummondii*, a fine hardy Pea with bright carmine flowers; *Libertia formosa*, a charming white flower with yellow stamens; and *Gunnera manicata*, fruit and young leaf, the latter singularly striking. First-class certificates were awarded for the *Gunnera* and *Lathyrus*, and a vote of thanks for the entire collection, which was a highly interesting one. Mr. R. Dean, Ealing, also had a first-class certificate for *Lathyrus Drummondii*. The plant was exhibited in a pot and trained to sticks. It was covered with reddish carmine flowers. This is one of the most distinct and attractive of the perennial Peas, and is well worthy of culture both in pots and borders. The same exhibitor sent cut blooms of striped *Antirrhinum*.

Mr. G. F. Wilson, F.R.S., exhibited *Polygonatum giganteum*, the North American Solomon's Seal, a stately plant growing to the height of 6 feet; also *Brodiaea volubilis* and the bright yellow *Cyclobothra pulchella*, and received a vote of thanks. Mr. H. Boller, 78, South Row, Kensal New Town, was also awarded a vote of thanks for a rustic stand having its base planted with dwarf succulents, and the top occupied with a drooping plant of *Othonna crassifolia*.

Mr. Pithers, Munster House Gardens, Fulham, exhibited tuberous *Begonia Illuminator*, having the brightest scarlet suffused orange-coloured flowers that we have seen. It is a fine decorative variety, but the plant was somewhat drawn. Mr. J. Kingsbury, Bevois Valley Nursery, Southampton, exhibited seedling *Petunias* and *Pelargoniums*, also *Coleus Empress of India*, richly marbled; and Mr. Donald Birchley exhibited yellow *Picotee Jane Birchley*.

From the Society's Gardens came fine examples of *Orchis foliosa*, also *Saxifraga nepalensis*, *Veronica brisicifolia*, a dwarf plant resembling a *Pimelea* and powerfully perfumed, also *Rhododendron hyacinthiflorum*. The trusses are large, and are composed of large numbers of small double flowers, colour purplish lilac; distinct and attractive.

NOTES AND GLEANINGS.

AN extensive Kentish cultivator draws our attention to what he describes as the MYSTERIOUS DISAPPEARANCE OF FRUIT. He is sanguine that if those who had such good reason a month ago to report so favourably of the fruit prospects will now examine their trees carefully they will have a very "different tale to tell." Fruit of all kinds, our informant states, has gone from the trees like magic. Frost, he states, is not the cause, nor are insects; for there has been no severe frost in his district, and the trees are much less free from insects than they have often been in previous years. We regret very much to hear such unfavourable tidings, coming, as they do, from a great fruit-growing district and from a successful cultivator and close observer. We can suggest one cause for the loss alluded to—namely, the extraordinary exuberance of the trees. It is well known that Peach trees which grow luxuriantly do not carry their crops so well as

do trees of moderate growth, and we suspect that excessive luxuriance, especially when it follows a season during which the wood was not well matured, has the same effect on more hardy fruits. We shall be glad to hear if the evil complained—for an evil it is—is common to other districts of the country.

— ON visiting the GREAT SUMMER SHOW AT SOUTH KENSINGTON on the fourth day (Friday) we were much impressed with the freshness of the plants and flowers. Although the weather during the Show was inclement, the temperature being low and showers prevalent, yet the plants did not appear to have sustained any injury by their retention in the tents. Some of the Roses were somewhat faded, but others were, if possible, finer than on the first day of the Show—notably *La France* in Mr. Turner's and *Alfred Colomb* in Messrs. Paul's collection, both of which were magnificent on Friday. The Orchids, too, were almost without bluishness, and the Azaleas remarkably fresh. In the amateurs' class for eight Azaleas Mr. Ratty had the first prize, and not Mr. Child as stated in our report of the Show.

— A MEETING of the General Committee of the NATIONAL ROSE SOCIETY was held at the Horticultural Club on the 28th ult., when the arrangements for the Exhibitions were made, and rules for judging, which we hope to publish shortly, were agreed upon. The following were nominated as Judges for the Crystal Palace Show:—The Revs. Canon Hole, E. N. Pochin, C. P. Peach, J. B. M. Camm, and H. Honeywood D'Ombra; Capt. Christy, F. J. Jowitt, R. G. N. Baker, and J. H. Arkwright, Esqrs.; and Messrs. J. Cranston, B. R. Cant, J. Cutbush, J. Mitchell, George Paul, William Paul, George Prince, Charles Turner, and H. Francis.

— WE have received the schedule of prizes of the GRAND NATIONAL HORTICULTURAL EXHIBITION, which opens in the Botanic Gardens, Manchester, on June 7th, and continues until the evening of the 14th. Prizes exceeding £1250 are offered—namely, £512 10s. in forty classes for amateurs; £610 in thirty-one classes for nurserymen, and £20 in an open class for the best collection of *Sarracenias*, *Nepenthes*, &c. In the amateurs' class for twenty stove and greenhouse plants the prizes are £35, £20, and £15; and for sixteen plants, eight in flower, £20, £15, and £10 are offered. The provision in this section is also very liberal for Orchids, Azaleas, Ferns, and *Ericas*; and £10, £6, and £4 are provided for collections of fruit. The Veitch memorial medal and a prize of £5 are offered for the best specimen Orchid. In the nurserymen's section are £50 in three prizes for one hundred hardy *Rhododendrons* in flower, and prizes of the same value for twelve large Roses, also for a collection of plants arranged for effect in a space 25 feet long by 15 feet wide. Many good prizes are also provided for stove and greenhouse plants, Orchids, *Rhododendrons*, and hardy shrubs. Such liberal provision, together with the high repute of the Manchester Botanical and Horticultural Society, together with the excellent management of the Exhibition by Mr. Bruce Findlay, ought to attract exhibitors and visitors from all parts of the country. The rules are commendably concise and explicit, the first being that "specimens may be exhibited from any part of the world and by any person, either for sale or for competition, or may be marked 'not for competition';" and "the prizes will be paid on the last day of the Exhibition." Thus the greatest possible inducements are offered to secure competition and a show of great magnitude.

— THE REIGATE ROSE SHOW has been fixed for July 6th, and will be again held by invitation in the grounds of A. J. Waterlow, Esq., of Great Doods, Reigate. The Society has this year thrown open the highest class to the amateur public. Four prizes of the respective values of £4, £3, £2, and £1 are offered in the new schedule for competition by any of the amateur Rose-growers in England who may desire to exhibit for the best twenty-four of any kind. The rest of the schedule, confined to members, is much as before.

— WE are informed that the Hon. and Rev. J. T. Boscawen has added £5 to Mr. W. Robinson's first year's PRIZES FOR ASPARAGUS. The first competition will be held for these prizes at the Bath and West of England Society's Show in 1881. Prizes will be offered for market-garden-grown Asparagus, as distinct from that grown in private gardens.

— ONE of the most cheerful displays of SPRING FLOWERS that we have recently seen is in the nursery of Messrs. Phippen and Robinson at Reading. Especially striking are the fine edgings of *Dactylis glomerata variegata*, which is employed

there almost wholly for spring decoration, and is extremely elegant. The flowering plants are chiefly composed of *Limnanthes Douglasii*, *Silene pendula compacta*, Daisies, and *Forget-me-nots*. In the nursery hardy flowers are cherished and cultivated, and we saw the first plant of *Arundo conspicua* that has come under our notice. About a dozen large houses are devoted to the growth of plants for decoration, and on the roofs of some of the houses *Stephanotis*, *Maréchal Niel* and *Gloire de Dijon* Roses are growing luxuriantly. That this nursery has been established and furnished so well in fifteen years is evidence that flowers are appreciated at Reading, and the active partner of the firm is an industrious and enterprising horticulturist.

— UPPINGHAM SHOW.—The school week of cricket, &c., at Uppingham is to be again most suitably enlivened by a flower show; for there is no surer way of gathering together the *élite* of a neighbourhood than a well-managed exhibition. At this Show we find by the schedule that liberal prizes are to be offered for cut Roses; and as the date (July 18th) suits the midlands we have no doubt that a fine display will be made, and we hope to record in due time a successful exhibition.

— WE last week referred to Mr. McIntosh's fine collection of *Rhododendrons*. Equally worthy of note is the rapid and excellent manner in which the capital ranges of new glass houses erected by Mr. Gray of Chelsea have been furnished. The condition of the VINES AT DUNDEEVAN planted last year reflects great credit on Mr. Taylor the gardener. The rods are not, as too often is the case, denuded of foliage near their base, but shoots are permitted to grow moderately down to the ground; this is an important point in securing a free thickening of the stem, and consequently ample sap-courses for the sustenance of the Vines and crop. The lower laterals of the Vines intended for fruiting are also treated more liberally than we often find them. They are not stopped to any particular leaf, but the principle is adopted of permitting the lower laterals to exceed in length those immediately above them, so that the appearance of the Vines may be described as a flattened pyramid, each Vine having a foliage base of nearly 5 feet. There need be no fear that Vines so trained will not produce bunches as large at the bottom of the rafters as at the top; it is undoubtedly the right principle to adopt in the training of Vines, and is worthy of mention at the present time and of extended application. Lilies and some other features of this admirably kept garden are worthy of attention, and will form the subject of a future "note."

— ALTHOUGH the noble GRAPE THE DUKE OF BUCCLEUGH has not succeeded with all cultivators, and it is commonly regarded as being a shy bearer, it is the reverse of shy at Chiswick. In a trial house of young Vines the Duke is producing bunches quite as freely as any other variety, and no Vine in the house is making shorter-jointed wood. The character of the Vine in those respects will be sufficiently apparent when it is stated that on a length of rod not exceeding 2½ feet there are ten bunches, all of which promise to be of good size. It will be interesting to observe how the crop progresses and finishes under Mr. Barron's care in a house containing nearly all the popular varieties of Grapes. Dr. Hogg is showing a magnificent crop, as also is Mrs. Pince; Black Hamburg, Royal Ascot, Golden Queen, Venn's Muscat, indeed all the varieties in the house, are in a highly promising state. They have never been nearly so fine before, and the borders have never had nearly so much water as during the past and present season. It is to copious waterings more than to any other cause that Mr. Barron attributes the excellent condition of the Vines and crop.

— WE are glad to learn that H.R.H. the Prince of Wales has been pleased to appoint Mr. John Wills one of the jurors of the horticultural section of the PARIS UNIVERSAL EXHIBITION. The shows for June consist of Orchids and Pelargoniums, both stove and greenhouse plants, open air ligneous plants, Roses, and forced vegetables and fruits, from the 1st to the 15th inst.; and from the 16th to the 30th of Roses, Palms, and Pelargoniums, Orchids, both stove and greenhouse plants, open air herbaceous plants, vegetables of the season, exotic and indigenous fruits, &c.

— WE observed the other day in the conservatory of Mr. Clifton, The Hollies, Fulham, a most attractive display of IRISES, LILYUMS, and WATSONIAS. Amongst those handsome plants the following are noticeable:—*Irises*: Dr. Margottin, Hassam Assam, Empress Eugénie, Susiana, Annie Jane, Leopoldine, Prince of Wales, Victorine, Amena, Darius, and

Miss Nightingale. Amongst *Watsonias Brevifolia* was the most noticeable, but many others are good. *Liliums* in flower are *L. giganteum* between 5 and 6 feet in height with six fine flowers, the expanded foliage also covering the pot; *Lancifolium rubrum* with fourteen flowers opening on one stem; *auratum* in quantity; *pardalinum*, *neilgherrense*, *Krameri*, *Humboldtii*, and *Brownii*. In this interesting garden may also be found several *Pompon Dahlias* flowering in a sheltered position as freely as they are usually seen in August.

— AT the POPULAR FLOWER SHOW to be held in the Royal Horticultural Society's gardens on Whit-Monday twelve medals and liberal money prizes will be awarded to artisans, &c., for collections of plants grown in the City of London, also for collections grown within a radius of five miles from the General Post Office and for single window plants, also for wild flowers gathered and arranged by children attending the various public and elementary schools. Messrs. Sutton & Sons, Reading, offer prizes for collections of vegetables. Prizes are further provided to be competed for by the London florists and growers for Covent Garden Market, the chief of which are £10, £7, and £5 for a group of plants arranged for effect in a space not exceeding 300 square feet; and £7, £5, and £2 10s. for a group of Palms and Ferns in a space not exceeding 200 square feet. Prizes are also provided for show and zonal *Pelargoniums*, *Fuchsias*, *Musk*, *Mignonette*, *Stocks*, cut flowers, bouquets, &c., and for any exhibits not provided for in the classes the Judges have one gold, two silver, and three bronze medals at their disposal. A very attractive display is anticipated, and such as will afford both pleasure and instruction to the thousands who will have the privilege of inspecting it for the small fee of 2d. each. The gardens will be open to the public at ten o'clock, and they will be admitted to the Show as soon as the judging is completed.

— AT a general Meeting of the Royal Horticultural Society held on the 4th inst., Lord Alfred S. Churchill, V.P., in the chair, the following CANDIDATES WERE ELECTED FELLOWS of the Society—viz., Victor Buckley, Lawrence Trent Cave, George P. Craven, Joseph Davis, Charles Dorman, John Downie, Samuel Edwards, Mrs. Fraser, Charles Godson, William H. Hilton, Lady Huntingfield, Colonel F. H. Rich, R.E., J. Rimington, Mrs. Duncan Roberts, Mrs. L. V. Swaine, C. G. Wilkinson, Mrs. Wyman, &c. J. R. Hale and Mrs. Hale were admitted guinea members.

— THE following, says Mr. Robert Coupar in the "Journal of Forestry," are the dimensions of a gigantic specimen of the SILVER FIR which is growing within 400 yards of Kinnaird Castle, Forfarshire, the seat of the Earl of Southesk. It is about 80 feet in height, and measures 22 feet 6 inches in circumference of stem at 1 foot from the ground; measuring 14 feet 11 inches in girth at 3 feet from the ground. At 5 feet from the base a large limb springs from the stem, measuring 9 feet 3 inches in girth at a foot from the point of junction. Excepting this large limb, the tree has a clear stem of about 18 feet in height to where it divides into several limbs, forming a large branching top. The spread of the branches averages about 56 feet in diameter, having an entire circumference of 176 feet, and forming a fine shapely head.

— A SERIES OF COLOURED PLATES of plants and flowers prepared by Mr. Fitch from specimens in the nurseries of Mr. B. S. Williams have been handed to us for inspection. They consist of admirably executed portraits of *Crotons*, *Pelargoniums*, *Azaleas*, &c., and afford evidence alike of the skill of the artist and of the excellence of the stores of the famed Holloway establishment.

FRUIT PROSPECTS.

I REGRET to say that I am not sanguine as to the present being an unusually good fruit year. Certainly in our west midland counties the statement of the writer of "Notes on Villa and Suburban Gardening" on page 378 cannot be endorsed, that "the prospects of most kinds of fruit could scarcely be better;" for while among small fruits *Strawberries* everywhere bid fair to be a prodigious crop, and *Black Currants* also promise well, *Red* and *White Currants* and *Raspberries* are not up to the average. *Gooseberries* also in my own warm and sheltered wall garden are for the first time in my remembrance an absolute failure, and in most gardens I have seen not half a crop. *Morello Cherries* are, as usual, setting well, but all other varieties, as a rule, have not set well, and promise a poor return. The same remarks will apply to *Plums*.

Some very early sorts in my garden grown against a south wall will give a partial crop, but most standards, especially *Damsons*, will again this year as last be almost a total failure.

As regards the prospects of the Apple and Pear crop it will be unusually interesting for growers to compare notes, as all the evidence as yet on record is very conflicting. On one point all must agree, that never could there have been a more beautiful and plentiful blossom; but the fruit is sadly disproportionate thereto. This disappointment should not be attributed, I believe, entirely to the nipping frosts we had in April, but to the long-continued wet and sunless weather, generating a condition of atmosphere favourable, with a fairly high and even temperature, to vegetable growth, but acting most unfavourably in an imperfect and barren germination. That this has been the case I am quite certain from the decimation of my late varieties of *Peaches*, *Nectarines*, and *pyramid Pears*, which shrivelled up and dropped off the trees quite an appreciable time after a good and safe crop apparently might have been expected.

I am afraid from what I have seen, travelling about a good deal in our west midland districts, that the above remarks hold generally true. Here and there enormous crops of *Peaches*, *Nectarines*, and occasionally, but very rarely, *Apricots* are to be seen (my own crop of *Apricots* is above average); but as a rule, as regards wall fruits impartial successes or total failures must be recorded. I freely make use of tiffany, but I find no protection so inexpensive and successful as the naturally flat, air-pervious, arching boughs of the *Yew* when due care is taken that no displacement from their position takes place to the certain injury of the tender shoots on the surface of the wall. This mode has already been mentioned in the Journal in terms of high commendation. I mention my own experience as bearing out most favourably what the writer then stated.

As regards orchard fruit in the west of England—and I am now writing from Devonshire—it is far too early to venture on a decided opinion, but I should say the crop would be above average. I take this opportunity of stating that I have never seen the old historic varieties of Apples, so many of which were laid low in the calamitous cyclone of last year, showing so prodigal a wealth of bloom, especially the *Fox-welp*; the wet summer, short spell of dry weather in autumn, and fine open winter of last year apparently exactly suiting these wonderful veterans, whose stubby lichen-sheathed summits are perfectly covered with blossom, though verily they must have been standing in their present position over two hundred years, perhaps before the days of the gentle and classic Evelyn, yet notwithstanding I much fear we shall not have half a crop of fruit.—THE HEREFORDSHIRE INCUMBENT.

BORONIAS.

How often do we hear the remark by gardeners that New Holland and Cape plants are out of fashion and not liked nowadays! But what is the cause of this? Why should they not be as well liked as formerly? The answer I feel inclined to give is that in many instances it is the gardener's own fault. A short time since, having furnished a nice spray of *Boronia Drummondii alba* for the decoration of a young lady's hair, it became quite the rage. No one could make out what it could be, whilst everyone admired its elegant appearance. From its use on this particular occasion several individuals have determined to add it to their collections; and thus I believe were these beautiful plants more frequently seen they would have as strong charms for the plant-growing public as ever.

In addition to the beautiful species and varieties which have long been known to the horticulturist, the Messrs. Rollisson and Sons of Tooting, and Messrs. Veitch & Sons of Chelsea, have rendered good service by the recent introduction of two species. The first-named firm brought to our notice *B. megastigma*, which, it is true, is not a showy flower, the outside being dark chocolate brown, within yellow. The flowers, however, hang in profusion like large beads upon the slender branches, and yield a powerful yet delicious fragrance like *Violets*, a small branch when cut being sufficient to perfume a large room; for this purpose *B. megastigma* is really invaluable, and those who are the fortunate possessors of this plant will seldom be without a small twig in the drawing-room or boudoir. The second-named florists were the introducers of *B. clatior*, a very fine species, somewhat robust in growth, and well furnished with foliage. The flowers are large for a *Boronia*, produced very freely, and bright rosy red

in colour, rendering it highly ornamental and extremely valuable as a greenhouse decorative plant; whilst looking upon it from an exhibition point of view, it is one of the very finest. Amongst older species we have *B. serrulata*, a charming plant with smooth, bright green, trapezoid leaves, and sweet-scented rose-coloured flowers. Truly a gem, but withal somewhat difficult to grow; indeed, with truth it may be said the most difficult species to cultivate in the whole genus. Another fine species is *B. pinnata*; the foliage is narrow, dark green, and divided into several pairs of segments; flowers large, pink,

sweet-scented, produced in great profusion, and last a long time in perfection. In *B. tetrandra* we have a free growing and flowering kind, with pinnate leaves and moderate-sized light pink or flesh-coloured flowers, which, however, do not last very long in full beauty. The last, though not by any means the least in point of beauty, we shall here mention is *B. Drummondii* and its variety called *alba*. In habit of growth it is more compact than the two last-named species. The plant when healthy is completely enveloped by large bright rosy pink flowers, which remain a very long time in perfection.

Fig. 66.—*BORONIA DRUMMONDII ALBA*.

The white variety is the exact counterpart of the species except in colour. For the opportunity of figuring this plant we are indebted to the courtesy of the Messrs. Rollisson & Sons of Tooting, in whose extensive nursery many rare and beautiful Cape and New Holland plants may be found.

Before leaving the subject a word or two about the cultivation of *Boronias* may be of service to some readers of the Journal. All the species may be increased by cuttings; they should be grown in good fibrous sandy peat, and be potted firmly like the genus *Erica*, the pots being well drained and the plants treated to an abundant supply of water during the summer season. During winter care must be taken with the water supply, and plenty of air should be given, but avoid cold and

cutting winds. After flowering the plants should be stopped and kept a little close until growth commences, when they may be repotted and encouraged in every possible manner to produce good growth for the next season's display.

AURICULAS AT FAILSWORTH.

THE day after the Manchester Show I again made a visit to Failsworth for the purpose of seeing the Auriculas at Mr. Jonathan Booth's, one of the few places where the newer and choicer varieties are to be picked up; and, more fortunate than last year, I had not, knowing my ground, to make the long tramp that I did then; and having made Mr. Booth's

acquaintance at the Show I was able to arrange so as to find him at home and have a talk together over our favourites.

As I mentioned last year, Mr. Booth grows his plants in a span-roofed pit heated with hot water; and the great convenience of this method of growing led me to alter my pit and turn it also into a span-roofed one, but not adding the heating apparatus. This is a modern innovation in Auricula growing; and whatever may be its desirability or necessity in the more leaden skies of the north, I do not think it can be either one or the other down south, and I rather fancy that even those who use it would rather dispense with it if they could. But the pit itself is a great advantage, especially to those who have passed their sixth decade, to be able to look their plants over at all times without fear of cold or wet; and hence I shall always look upon my visit to Failsworth last year as a turning point in my cultivation of Auriculas.

Mr. Booth's collection is an extensive one—constantly changing indeed, as those of all growers for sale must change, but the vacancies by sales in which he is continually filling up. And here let me say that it is a mistake to suppose that it is difficult to purchase these plants. There are some of the newer and scarcer kinds which are not to be had, but there are not more than half a dozen in this condition, while there are numbers which can be purchased for a comparatively small sum which are not only beautiful but also winning kinds, and no one need be frightened by the bugbear that they are not to be had.

It is remarkable, too, that notwithstanding the new varieties the older ones still hold their place. Thus in the single-plant showing, where the new and old are pitted against one another, it is consolatory to beginners to find that they are not altogether sure to be distanced by the possessors of new varieties. Taking the Crystal Palace Show, I find such flowers as Hudson's Apollo second and Beeston's Apollo fifth in green edges; Lancashire Hero second and Sykes' Complete fifth in grey edges. In white edges Summerscales' Catharina first and fourth, McDonald's Miss Ashley seventh and eighth, Catharina thus beating Smiling Beauty and John Simonite; while in selfs Pizarro, Meteor Flag, and Eliza, all old flowers, took nearly all the prizes.

The letters that have appeared in the Journal relative to classes which shall be open only to small growers, and the satisfactory answer of Mr. Dedwell, are indications of a right estimate of the situation; in fact it is with this as with all other things, the "victory is on the side of big battalions." Other things being equal, a small grower has little chance. A man who grows four thousand Roses is pretty sure to beat a man who grows three hundred on the show day if both are good growers; and so one who has twenty or thirty plants of a good winning Auricula is more likely to have one or two ready for the show day than the grower who has only a couple of plants of the same variety; and so the possessor of five or six hundred plants is pretty sure to distance the man who only has a few dozens. Hence there can be no surer way in which to encourage the growth of these beautiful plants than offering prizes to those who are the possessors of small numbers.

It is sometimes laid down as an essential matter in growing Auriculas that they should not be overpotted; but one of the very best growers in the north, Mr. Wilson of Halifax, grows his in the old Lancashire "moogs," which are fully 5½ to 6 inches across inside measure, and nowhere north or south can such plants of Leigh's Col. Taylor be seen as with him.

In going through Mr. Booth's houses I saw in quantities more or less the following, which are procurable. In green edges, Ashton's Prince of Wales, Campbell's Admiral Napier, Hudson's Apollo, Litton's Imperator, Oliver's Lovely Anne, Traill's Mayflower, and General Niel. In grey edges, Cheetham's Lancashire Hero, Clark's Mary, Dixon's Lady Jane Grey, Headly's Alderman C. E. Brown, Kenyon's Ringleader, Lightbody's Richard Headly, Robert Traill, and Sir C. Napier; McLean's Unique, Smith's General Bolivar, Sykes' Complete, Waterhouse's Conqueror of Europe, and Williams' Squire Chilman. In white edges, Campbell's Robert Burns, Heap's Smiling Beauty, Lightbody's Countess of Dunmore, McDonald's Incomparable, Poppleworth's Conqueror, Smith's Ne Plus Ultra, Summerscales' Catharina, and Traill's Beauty. And in selfs, Campbell's Pizarro, Kaye's Topsy, Lightbody's Lord Clyde and Meteor Flag, Martin's Mrs. Sturrock, Smith's Formosa, Spalding's Blackbird, Sims' Vulcan, and Turner's Charles J. Perry. Let anyone take the list of winning flowers at the Crystal Palace and Manchester, and they will see how large a number of these are to be found amongst them, and that if

they wish to commence a good collection there is no difficulty in the matter. Most of these are moderate in price; but if persons are in ecstasies over flowers and yet refuse to spend a moderate sum on them they cannot expect to be considered as very zealous in the cause. On the other hand there are a few which at present are next to impossible to obtain. Thus, amongst older flowers Leigh's Col. Taylor, Booth's Freedom, and Taylor's Glory are not often to be met with; while amongst the modern ones George Lightbody, Dr. Horner, George Levick, and Ellen Lancaster are difficult, although I am not sure that Mr. Booth may not be able to supply them; and Alexander Meiklejohn and Prince of Greens impossible—at least I have tried in every direction to get the former and have failed, so that really the impossible are a very small item. The notion has somehow got abroad that these flowers are not to be had, and hence I have written this; and what Mr. Booth can do in the north I believe also Mr. Turner can do in the south. I noticed, moreover, at the Manchester Show that another successful exhibitor, Mr. Royd, brought his flowers in the same large pots. This, too, was the practice of the best Auricula grower I ever knew, Dr. Plant of Monkstown, who used to say that if you didn't give boys room to grow how was it possible they could ever come to be men? It would thus appear that no hard-and-fast line can be laid down, and that the Auricula is more accommodating than is sometimes supposed.

The record of my visit to Failsworth has led me off into other matters; but the fact is the Auricula is an enticing subject, and there is always something one wants to learn or say about them; and all who love the plant will, I am sure, pardon the irregularity of these few notes.—D., Deal.

PEAR-GROWING IN SUSSEX.

It is not surprising that the appearance in the *Sussex Weekly News* of an article descriptive of 60 acres of land under cultivation as one vast Pear tree garden at Slinfold should create a stir in that somewhat drowsy county, where until now its very existence appears to have been comparatively unknown. The point of assumed secrecy is evidently sheer nonsense, as the plantations referred to have their approach from the main turnpike road, and are planted on both sides of it for some hundreds of yards before entering on their more extended proportions, the graceful outlines of which are attributed to Milner. Daily, now for a period of four years, have the orchards been visible to every passer-by; no hiding under a bushel has been resorted to, although none but certain experts and lovers of fruit culture have roamed among these experimental groves. The real cause of apparent privacy is traceable to Sussex incredulity in anything unless originating with the aborigines. During all the years employed in preparing and planting these gardens utter failure has been the cry of all but skilled gardeners; these, however, have from the outset recognised that the projector was no novice, but rather a practical sledge-hammer hand, to whose untiring energy and mastery of his subject success was a clear certainty.

Major Walter—who owns, and who may be said to have created these 60 acres of Pear orchards—is doubtless an enthusiast. We hear that some nineteen years since he unaided raised and equipped in Liverpool the first complete brigade of volunteer artillery formed in the kingdom. His labours in setting this national movement going were looked upon as a dream, for in one fortnight seven hundred young men and a complete staff of officers of the very *élite* of Liverpool recognising his energy and patriotism rushed to the banner he unfurled. The late Earl of Derby spoke of him as "the indomitable enthusiast through whose energy the volunteer movement was kindled and fed." Surely, then, there need be no surprise that like force expended in pomology as a favoured pursuit of such a mind should impart matter of interest to horticulturists.

On some future opportunity we hope to give our readers a description of the Slinfold plantations, meantime we feel it our duty to warn the sanguine against exaggerated ideas as to the profit likely to arise from the venture. It is easy to put forward glowing statements, but the retail price even of Pears and the pocket receipt of the grower are often wide as the poles asunder. Four years have already elapsed since many of the trees were transported to their Slinfold home. From that time until now all has been outlay of money, and the aggregate must be large. "All is not gold that glitters," even in fruit-tree culture. In due time there will, we do not doubt, be a well merited and earned reward, but we are bound to add

that where one under precisely similar circumstances could command success, ten would most probably have failed in such an untried enterprise.

The *Sussex* paper thus refers to these plantations:—"Great interest has been awakened among our *Sussex* horticulturists by an attempt on a huge scale at Pear-tree growing at Slinfold near Horsham; and although the enterprise has so far been quietly and unostentatiously prosecuted without public attention being drawn to it, yet the work is being watched with extreme interest by pomologists and the leading spirits of the county. Notoriety has recently been given these extensive plantations through an article in the *Dumfries Standard*, from the pen of a known Scotch writer who has recently been visiting the locality. Under the head of a 'Rural Note from the Weald of Sussex,' the Scottish writer thus descants:—"A dear old friend has purchased a charming property in the Weald of Sussex, and turned 60 acres of it into a Pear orchard, in which he has already planted many thousands of Pear trees of the very finest sorts, collected from the best parts of England and the most famous orchards in France, Belgium, and Italy. Some of the trees are as much as twenty years old, raised by the proprietor at his former beautiful place in Cheshire, some from Normandy, and some from the far south of France, and yet but few have been lost, so tenacious is the Pear tree of life. Anything more lovely than the orchard is now it would be difficult even to imagine. The property is on a somewhat highly elevated undulating plain, of a clayey loam soil, deep, and rich; when wet as adhesive as mortar, when dry it pulverises and assumes the appearance of delicate yellow ochre dust. Fancy yourself standing on the highest point of ground, where by-and-by a residence will be built, and looking over 60 acres of trees in full blossom, white as sheeted snow, spreading a perfume sweet as the odours that may have floated over the garden of Eden, and then you will be able to estimate the loveliness of the future home of my friend Major Walter. The view is very extensive. Looking to the south you have the whole of the Southdowns in view, stretching from Chichester to almost Beachy Head, and to the north the lovely Surrey and Kentish range of hills from Guildford to Sevenoaks, commanding a prospect of nearly thirty miles all round, whilst the central landscape is watered by the Arun, which, winding past the old castle of Amberley and the grand feudal pile of Arundel, enters the sea at Littlehampton. Nithsdale even is not more beautiful.' It may seem odd that a canny Scot should first publicly draw attention to this *Sussex* fruit forest, of which the county will doubtless be proud, even though until now its existence has been kept in the dark. The owner, however, is well known in the horticultural world as a Napoleon of Pear tree culture, and as having been engaged some twenty years at his former home in Cheshire in bringing forward a vast number of these trees now flourishing at Slinfold. Thousands of them varied from twenty to five years old when their removal into *Sussex* was commenced, now four years since. We admit that none but a man of extraordinary energy could have successfully carried out such a seemingly perilous enterprise. That it is a success no practical pomologist now doubts. There stand the trees, and during the last fortnight they have certainly presented a very lively appearance, as described by the Scotch writer. When first embarked in, their removal was looked upon by many as Quixotic. As a rule *Sussex* men do not entirely believe in matters in which they have had no hand, and apart from riskiness much doubt was cast on the suitability of the soil. We confess never to have questioned this vital feature. Many parts of *Sussex* produce beautiful fruit. We are nearest to the Channel Islands; in fact, we believe that it vies with the hitherto most favoured districts of England, and may yet prove the garden for the finest fruit products. It is satisfactory to know that this project, fraught with such interest to the county, rests with a skilled and determined hand. A large amount of capital and labour have been expended on these orchards at Slinfold, all the land has been thoroughly trenched, and every means taken that skill can devise to command success. If, therefore, the climate and soil are suited we may rest satisfied this will be attained; indeed, the undertaking is now removed out of the zone of doubt. Slinfold is doubtless one of the most picturesque villages in the county. Major Walter, if we mistake not, is well known among all the leading pomologists of Europe. Such men as the author of 'Lorna Doone' and 'Alice Lorraine,' an earnest lover of fruit tree lore, many of whose charming descriptions of rural scenery are from *Sussex*, Dancer of Chiswick, and Barron of the Royal Horticultural Gardens

are, if we mistake not, familiar with all that is being attempted at Slinfold. The magic touch of the landscape garden artist, Milner, is traceable in the outlines of Major Walter's orchards as in the general arrangements for outlay of the estate. Milner is not alone in aiding the refined and picturesque doings on his fruit farm, which, if we mistake not, is destined to be an important feature in pomological development."

OUR BORDER FLOWERS—BITTER VETCH.

WHO has not in the spring and early summer time by the way in shady woods and sunny slopes stayed to admire our own Bitter Vetch (*Orobis tuberosus*) with its purple-red Pea-like flowers? Why is it not taken into cultivation by the lovers of border flowers now that we are having a run for spring bedders? Is this beautiful native overlooked, or is it too common for cultivation? To me at least it has its charms. Lightfoot tells us that it finds more favour over the border in the Highlands of Scotland, where they dry and chew the roots to give a better relish to their liquor. Likewise they are said to be effective in chest disorders. By their use they are enabled to repel hunger and thirst for a long time. In some places they bruise the roots and steep them in water, and make from them an agreeable fermented liquor. They have a sweet taste, somewhat like liquorice, and when boiled are well flavoured and nutritious. In times of scarcity they served as a substitute for better food. In Holland and Flanders they are said to boil them until a fork will pass through them. Dried slightly and roasted they are served up as Chestnuts are, which they somewhat resemble in flavour. A plant with so many useful qualities to recommend it ought no longer to remain in obscurity.

The Spring Bitter Vetch (*Orobis vernus*) is a charming border plant in early spring, and is rather impatient of removal. It may be increased by division and raised from seed: I prefer the latter mode. The seed is best sown in the spring in rich light soil either in pots or sheltered borders. When the plants are large enough plant them where they are to remain. In time they form large plants, and are very beautiful when established; they last many years. They are at home in good loam and a fully exposed and moderately moist situation, where they may be left to shift for themselves. The Upright Bitter Vetch (*O. lathyroides*) is a showy border flower in early summer, and ought to be met with much more frequently than it is. It requires room for development and support to keep it from being blown about by the wind. It is best raised from seed, and is not particular to soil provided it has light and moisture. The Yellow Bitter Vetch (*O. luteus*) ought to be in every collection; its dense racemes of pretty yellow flowers are produced in profusion at midsummer. It is of moderately dwarf habit, which adds greatly to its beauty. The Variegated Bitter Vetch (*O. variegatus*) is perhaps the most striking of the family, and is also of dwarf habit, and flowers in the spring. The Hoary Bitter Vetch (*O. canescens*) from across the Channel is comparatively of recent introduction, but ought to be in all collections. It is highly desirable for border or rockery. It is light blue in colour, and keeps long in flower. The White-flowered Bitter Vetch (*O. albus*) is of somewhat delicate appearance, but when established is a fine border plant. It thrives best in a moderately dry and partially sheltered situation. A free loam with sandy peat meets its requirements, and when established needs little further care. There are many others of this race that might be enumerated which with moderate care cannot fail to give satisfaction. This is a race of plants that needs taking in hand by cultivators, for they are worthy of extensive cultivation.—*VERITAS*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

GET out a good breadth of Celery, for though the plants make much progress in the autumn they must be planted early if good well-blanced heads are expected. The earliest rows now established must not be neglected for water and liquid manure. Plants that are growing under handlights will soon be ready for a good earthing; the lights will have been removed some time. A good watering should be given previously to the earth being applied. Afford copious supplies of water to Cauliflowers, also to successional crops, pouring liquid manure also between the rows. Make a practice of planting out a breadth of Cauliflowers every fortnight or three weeks. Dwarf Kidney Beans sow if required. We sow every fortnight or three weeks from late April until early July. Now that Peas are coming in relax the cutting

of Asparagus, and at once commence feeding the beds with liquid manure. Nothing injures Asparagus so much as late cutting. Young plants may now safely be transplanted, being careful to lift them with all the roots practicable, and keep them from the sun. If no Cauliflower seed was sown as advised for the Michaelmas crop it must at once be got in. We like to sow a pinch of seed now in addition to that sown in late May. The plants from this sowing come in very late, and are useful for lifting to store in frames. Globe Artichokes delight in nothing so much as broiling sun and abundant water at the root. Peas, if the weather be dry when they are coming into flower and have begun to slat, apply water along the sides of the rows and mulch with short litter. Attend to Cucumbers and Vegetable Marrows under handlights, carefully admitting air freely in fine weather. When the bines commence running raise the lights upon bricks at the corners to admit of their spreading outward. To ensure early Marrows do not neglect to impregnate the female flowers. Ply the hoe frequently between the rows of growing crops, which is all that is necessary to keep down weeds in fine weather, but in moist weather hand-weeding may be necessary to keep them from seeding, which must not under any circumstances be allowed. The earthing of second early and late garden crops of Potatoes must be completed. The early crops are all that could be desired and are tuberizing well, but the second earlies have come very unevenly, particularly Lapstone, and "curl" is already showing itself.

FRUIT HOUSES.

Figs.—Continue the directions previously given about those ripening for fruit; whether in pots or planted out a good mulch should be given, and the waterings through it will carry nutriment to the roots. When the first crop is all gathered syringe the trees twice a day, and afford them more water to assist the swelling of the second crop. If the fruits set too thickly they must be thinned, for if too many fruit are allowed to ripen they will be small in size and badly flavoured. The earliest forced trees will, if required for the same purpose another year, be better adapted for early work, especially if the trees are weak, by not allowing them to perfect a second crop, although if vigorous a second crop may be taken without impairing them for next year. Keep them in the house until the wood is ripened, when place outdoors in a warm situation, the pots being plunged in ashes, and kept well watered and mulched; the trees will then be in fine order for early forcing. In later houses the shoots will require tying-in, thinning where too thick, and stopping. When the fruit commences ripening, the supply of water to the roots and the syringing must be gradually diminished until the crop is all gathered.

Pines.—About this time the plants intended for affording fruit in early winter will be showing signs of fruiting. This will be the case with the plants that were shifted into the fruiting pots in September; if not, they should be rested for four to six weeks by reducing the temperature at the roots to 75°, ventilating freely, opening at 75° and closing at the same degree, and employ fire heat only to prevent the night temperature from falling below 60°. Do not allow the plants to become very dry at the roots; but when water is required give it liberally, for to keep them dry as dust is very injurious to the plants. Small suckers not shifted into the fruiting pots in September, but kept in small pots over the winter and shifted into fruiting pots in spring, should be kept growing on for a month or so longer until the pots are well filled with roots, and being then subjected to the treatment advised for the larger plants they will afford a successional supply of fruit. Queens and Providence Pines which started into fruit in February will ripen this month, they requiring less time to arrive at perfection than any other kind; hence their suitability for early summer use. Although a Providence is not equal to a Queen in quality, yet large fruits are often in request for the sake of their noble appearance. Smooth Cayennes, Charlotte Rothschild, and similar kinds require about a month longer to ripen properly than Queens under similar treatment, affording a successional supply of ripe fruit, which may be further extended by removing some of the plants with the fruit to a cool airy house. When the fruit commences colouring cease syringing, gradually diminishing the supply of moisture in the house, but afford water to the roots as required. Both the colour and quality will be improved by freer ventilation, but not so freely as to reduce the temperature below 80° by day, maintaining the night temperature at 75° to 70°. Maintain the bottom heat at 80° to 90° to all plants excepting those being rested.

Cucumbers.—Strawberry houses, houses occupied by Vines in pots, and structures employed for wintering bedding plants, will soon be cleared and may be employed for growing a late supply of Cucumbers. The plants may be grown in pots 12 or 13 inches and larger, draining them well, and only partly filling them with compost, so as to leave space for fresh additions. They may be plunged in spent tan or other material. A wood or other description of temporary trellis may be improvised at 15 inches distance from the glass. No fire heat will be necessary, the house being closed between 8 and 4 P.M., syringing then, the floors and every available surface being kept damped so as to secure a good moisture during the day; but do not syringe in the morning, it

often being the cause of great mischief to the foliage. Admit air at 75°, and allow the temperature to rise to 85° or 90° with sun and increased ventilation, closing at 80°, and if the temperature rise to 85° or 90° afterwards all the better. In the Cucumber house fire heat will only be required to keep the temperature from falling below 70° to 65° at night, and 75° to 70° by day by artificial means will be ample. Attend well to stopping the shoots, removing bad leaves, well thinning out the old growths, and watering copiously with weak liquid manure about twice a week. Pit and frame Cucumbers may be watered and closed at about 4 P.M. or earlier according to the weather, but it must not be done so early as to cause the temperature to rise above 90°. Liquid manure may be given occasionally, but it should not be allowed to wet the foliage.

Melons.—Some difficulty is sometimes experienced in getting the blossom to set and fruit to swell freely; more particularly is this the case with plants in frames. It usually arises from the atmosphere being too moist and the plants too crowded with foliage accompanied by cold. Anything like crowding of the shoots is fatal to a good set, therefore the shoots should be kept rather thin by removing every alternate lateral whilst quite small, for to remove them when large very often induces canker. The laterals retained should be stopped two joints beyond the first female blossom. When those show fruit water should be given if necessary, pouring it between the shoots so as not to wet the surface to any great extent. Some hot dung should be placed against the sides of the frames, or grass mowings will do with a little long litter over the grass. This will raise a gentle warmth, admitting of a little air being left on constantly day and night—about half to three-quarters of an inch, which prevents deposition of moisture upon the blossom, which is fatal to fructification. Impregnate the flowers when fully expanded, being particular to touch the stigmas of the female with the anthers of the male, which is readily performed by denuding the flower of the corolla. Air should be freely admitted if the weather permit, increasing the ventilation at 75°, allowing it to rise to 80° to 85°, closing at 75°, except the small portion before alluded to. When two or three fruit are set and the size of a bantam's egg, commence watering by sprinkling overhead at closing time, always keeping the water from the neck or collar of the plants, and besides the sprinkling give a good watering twice a week in hot weather; once, or not that, will be ample in dull weather. Commence giving air at 75°, allow the heat to rise to 85° or 90°, close at 80°, or between 4 and 5 P.M. with a gentle damping. When the fruit is advancing for ripening, or about forty days after it commenced fairly swelling, keep the bed well lined with hot dung or grass mowings, and admit air freely, leaving a little on constantly, omitting the sprinklings overhead, and water through the spout of the watering pot instead of a rose, so as to keep the surface of the bed dry. Cut the fruit not more than a day after it commences giving off its aroma, placing it in a dry room, and in two or three days it will be in perfection, which is when the ripening colour pervades every part of the fruit, after which flavour is lost rapidly and in a few days entirely gone. A badly ripened fruit is not nearly so insipid as one over-ripe. Cut back the bines of those from which the fruit has been cut, remove a little of the surface soil, replace by fresh, and give a good watering. If due regard has been had to keeping the soil moist for the first crop fresh growth will be quickly made, and fruit will speedily set and swell; indeed we have fruit set and swelling freely before the first fruits are cut, having encouraged fresh bines from near the collar of the plants. Some cultivators keep their plants so dry at the roots during the growth and ripening of the first crop as to completely exhaust the plants and in many instances spoil the fruit, it ripening prematurely, and consequently is flavourless.

PLANT HOUSES.

GREENHOUSE.—*Mignonette* for autumn and winter flowering should now be sown. There is now great variety. For general purposes Queen Victoria is unsurpassed, it and Giant Red Pyramidal being the best "reds." Parson's and Garraway's White and Miles's "Spiral" being all good in their section. We sow in small pots, a few seeds in each, in a cold frame; when the plants are about an inch high we thin them, leaving one in each pot, shift into pots a size larger as the pots fill with roots until they are in 9-inch pots; the pots are placed on ashes in a sheltered but open situation, staking so as to prevent the shoots being broken, and pinching off all spikes of bloom as they show until the middle of September, when the plants are assigned a light airy situation in a house having a temperature of 60°, and they flower through the winter. They are fed with liquid manure after the 9-inch pots are filled with roots, but are carefully watered in winter, allowing the soil to become dry before giving any and yet before flagging. Smaller plants are had for decorative purposes by sowing about six weeks hence. Turfy loam with a free admixture of sand and charcoal, both to the extent of a fifth of the loam, form a suitable compost with thorough drainage.

Heliotropiums.—Take cuttings now of strong healthy growing shoots, insert them singly in small pots, and place in gentle heat. When rooted remove them to a cold frame, gradually harden off, and shift into 6-inch pots; return them to the frame, admitting air

freely. When the pots are filled with roots shift the plants into 7-inch pots, and place them on ashes in an open situation and keep them well supplied with water. Pinch out the bloom as it shows until September; at the end of that month place them in a light airy house with a temperature of about 50° by artificial means, and feed them with liquid manure. They will bloom all the winter, and are useful for cutting or decoration. Larger plants may be had by potting now healthy plants from small pots, shifting them on until they are in 10-inch pots, and then feeding them with liquid manure, keeping off all flowers until the plants are placed under glass in the autumn.

Azaleas out of flower will be making growth, and should be at once repotted—i.e., if they require it, but avoid overpotting, they not requiring nearly so much pot room as many other hardwooded plants. Keep the house close and moist for a few weeks after potting, shading from bright sun. Employ sandy peat broken up small, adding about a fifth of silversand, drain well, and press the soil very firmly around the ball, leaving a space of about an inch for watering for a 7 or 8-inch pot, and proportionate increase of depth for the larger sizes, as these plants require abundant supplies of water. If thrips infest the plants syringe them with tobacco water diluted with six times the quantity of water, or if fumigation be resorted to be careful not to injure the foliage by an overdose. When the growth is complete admit air freely, and gradually reduce the shading with a view to the ripening of the wood and the setting and thorough development of the buds.

Camellias.—Late-flowering varieties will be making growth, and are benefited by weak liquid manure, unless the plants are very luxuriant, when it not infrequently does harm by increasing the vigour and inducing a second growth. We had blooms of Beali and Candidissima at the end of May. Weakly plants should have manure water until the buds are set. They should never become dry at the roots, and, on the other hand, not be made sodden. Plants placed in heat after flowering early will have set their flower buds, and should be placed in a cool airy house, one preferably with a north aspect, or under temporary lights behind a north wall, which is better than placing the plants outdoors to be drenched by rains, which often causes loss of roots to an extent causing the dropping of the buds at a later stage, often when they should be expanding for flowering. Our plants are never placed outdoors, and we have blooms from October to May inclusive.

Small plants of *Petunias* should be potted and grown on in a cold pit, affording them plenty of light and room. They do well in turfy loam with a fifth of leaf soil or well-decayed manure, adding about a sixth of sand. If showing for flower on one stem stop them to induce side shoots, but not very closely. Six or 8-inch pots are large enough. They are fine for blooming in late summer. Shift *Fuchsias* intended for late bloom into larger pots, stopping the shoots as they need it to induce dense growth, and if plunged outdoors in a sheltered situation they will have very much better foliage and flower more finely than by growing them under glass, they being removed indoors about a month before wanted to bloom. Cuttings of zonal *Pelargoniums* now inserted singly in small pots strike freely in cold frames, and if grown on through the summer make plants that in a temperature of 50° from artificial means will grow and flower all the winter through in 6 or 7-inch pots. Young plants are very much better than "cut-backs," giving larger trusses and blooms. Balsams may yet be sown for September flowering, and very useful they are at that time when there is little else. Cockscobs after the "combs" appear should be fed with liquid manure. They do well after this in a cold frame, which should, however, by early closing be kept at a hot-bed temperature. When the combs are full-sized they are fine for decorative purposes. *Celosias* should have every encouragement by being shifted into larger pots until they are in their blooming pots, and then feed them with liquid manure. The flower heads both upon the leads and side shoots should be pinched out, and they will then afford plenty of feathery sprays. Well-grown plants are very useful for the conservatory in late summer. *Tuberose*s to flower late should be potted in moist soil and plunged in bottom heat until fairly on the move, when plunge them in ashes in a cold frame and water them as required. Another lot may be potted at the end of the month for flowering late in the year, and when they are specially acceptable.

STOVE.—Spring-struck cuttings of *Eranthemum pulchellum* should be potted in 6-inch pots, also *Aphelandra cristata*. They do well in equal parts of peat and loam, with a free admixture of sand, and good drainage. *Aphelandra aurantiaca* Roetzli is very desirable from its dwarf growth and fiery orange-scarlet flowers. It also should be encouraged to make growth, but do not overpot, the plants doing well in 4 to 6-inch pots. They should be kept near the glass. Cuttings of *Conoclinium ianthinum* may now be inserted in sandy soil, and be placed in bottom heat; when rooted shift the plants into 6-inch pots. Old plants shift into larger pots. Fibrous loam with a little leaf soil will grow it perfectly. *Thysacanthus rutilans* is a fine old plant and should be grown-on in a light airy situation. *Centradenia rosea* and *floribunda* shift into larger pots, and stop the shoots as required. *Francisceas calycina* major and c. *Hopeana* will now have completed their

growth and should have a light position, but not be allowed to suffer for water, and they will flower again in autumn or winter. They are fine decorative plants. Cuttings when well rooted of *Euphorbia jacquiniæflora* pot off. The plants should be stopped once and no more, or the sprays will be weak. Avoid overpotting and overwatering, but afford enough of the water to maintain the plant's lower leaves. Loam is the most suitable compost. If there be a border at command wherein to insert the plants do so, well draining it, and using good turfy loam. The situation must not be shaded. Plants grown in pots are far behind those planted out for affording flowered sprays for cutting. *Poinsettias* when well established in pots, whether old plants or young, must be grown-on near the glass, and are best after the middle of the month placed in cold frames or pits, the object being to induce sturdy habit. *Gesneras exoniensis*, *zebrina splendens*, *cinnabarina*, and others of that type, must be encouraged to make growth, and they must not be grown in the shade, though a slight shade from bright sun is desirable. If for decorative purpose one large corn in a 6 or 7-inch pot will be sufficient, but five or more may be placed in an 8 or 9-inch pot. *Tydeas* must not be neglected, as too often is the case, they being among the finest of winter-flowering plants, and should have light airy situations, but not draughts of cold air. *Gloxinias* for late blooming should be encouraged. If the seedlings have not been potted off lose no time in doing so, and grow them on shelves slightly shaded. They will bloom finely in late summer and autumn. *Scutellarias* keep near the glass, and give them weak liquid manure. Insert successional cuttings of *Poinsettias*, taking them off with a good heel, also successional cuttings of *Euphorbia jacquiniæflora*. It is hardly possible to have too many plants for winter flowering, but crowding is one of the greatest evils in plant culture; a few plants well grown are better than a great number in poor condition. *Rondeletia speciosa* and *major* should have a light moderately airy situation, and be kept well syringed to prevent thrips and red spider. When well grown it is a fine plant for late summer. *Lasiantha macrantha*, with its bright deep purple salver-shaped flowers, is a good late-summer-flowering plant, but to bloom well must be near the glass and have plenty of light, also room, as it grows tall. The dwarf variety *floribunda* is very much more tractable and freer-flowering. *Burchellia capensis* should have encouragement; it requires plenty of air, light, moisture, and not too much pot room. *Clerodendron Balfourianum* and *Bougainvillea glabra* when they have ceased flowering should be placed in a drier and cooler house fully exposed to the sun, not watering them until the leaves flag. Continue this treatment for six weeks, and then place them in the stove and water them copiously, occasionally with weak liquid manure, and syringe them twice a day. They will start again freely and flower well in late summer. *Allamandas* encourage with weak liquid manure, also *Dipladenias*, but the last do not require nearly so much water as *Allamandas*—indeed should not be watered until they become quite dry. Roof-climbers must be frequently attended to in thinning and training, and when coming into flower give the border a good soaking with liquid manure. *Centropogons* should be encouraged, turning them out of the pots, removing the old soil and returning to the same or a smaller size of pot. Grow them in a cold pit, keeping it close and shaded for a time until the plants are established, then admit air moderately, and sprinkle and close early in the afternoon. *Monochætums* should be treated in the same way, the object being to have them stout. They do well in loam with a little leaf soil, and not overpotted. *Imantophyllums* are growing freely, and should be encouraged with weak liquid manure. They like plenty of light, also moisture when growing. Strong plants flower two or three times a year. If more pot room is required give it. We grow them in lumpy loam with a modicum of well-decayed manure. *Amaryllises* examine for mealy bug, &c. Wash the leaves with a sponge, and keep the plants well supplied with water. They require a position near the glass fully exposed to the sun. *Urecolina aurea* keep near the glass and duly supplied with water until the leaves turn yellow, when a little water now and then just to keep the soil moist will preserve the bulbs. *Achimenes* and *Gloxinias* showing for bloom keep well supplied with weak liquid manure. *Meyenia erecta* if liberally watered with liquid manure, and moderate pot room is afforded, will flower all through the summer. *Thunbergia Harrisii*, and *T. laurifolia* also, if duly fed and kept clean afford a succession of bloom over a lengthened period. *Anthuriums* when flowering and making fresh growth should have an abundant supply of water and air-moisture, and be near the glass, with slight shade from bright sun. These fine decorative plants should be grown in quantity, their flowers (spatheas) being very enduring.

TRADE CATALOGUES RECEIVED.

John Laing & Co., Stanstead Park Nursery, Forest Hill, London.—*Catalogue of Stove and Greenhouse Plants, Florists' Flowers, Roses, Vines, &c.*

William Bull, King's Road, Chelsea.—*Illustrated Catalogue of New and Rare Plants.*

Osborn & Sons, Fulham, London, S.W.—*Catalogue of Herbaceous, Bulbous, Alpine Plants, and Hardy Ferns.*

Ant. Roosen & Son, Overveen, Haarlem, Holland.—*Catalogue of Dutch and Cape Bulbs, Aroids, Terrestrial Orchids, &c.*

TO CORRESPONDENTS.

HEATING BY A PARAFFIN LAMP.—*"One in a Fix"* asks whether any of our readers have a boiler heated by a paraffin burner; if so, whether they would give instructions how to make the stove. He could make a boiler and pipes to be heated by a gas-burner, but cannot understand how the boilers heated by paraffin are made, because if a boiler is fixed over the lamp soot would collect at the bottom of the boiler and drop down the glass of the lamp. If any of our readers would give plans for any kind of stove that does not require a smoke chimney they would be doing a great service to many.

ROCKWORK.—*J. House* wishes to be informed where a light open shelly sandstone suitable for rockwork can be obtained.

HEDGE-EATING INSECT (*J. G.*).—The caterpillar is the larva of the Little Ermine (*Hyponomeuta padella*), the only effectual remedy for which is the destruction of all noticeable webs containing either larvae or pupae. You have not, we think, reason to apprehend that the pest would kill the bushes. We have never found that occur, even where the species attacked hedges already weakened by the ravages of other larvae. Soot would not be likely to do much good. Were it possible, however, to syringe the hedges many of the insects would be killed, moisture proving prejudicial to them.

SAWDUST MIXED WITH DUNG (*An Employer*).—It does not render the dung objectionable for application as a manure. The sawdust decays more gradually than the dung.

THRIPS ON VINES (*J. B. B., Ballymacod*).—We never saw a Vine leaf more thickly infested with this destructive insect than the leaf you have forwarded. If the whole of the foliage is similarly infested your Vines will receive serious and permanent injury unless you promptly adopt remedial measures. We advise you to have every leaf sponged with a solution of soft soap, 2 to 3 oss. to the gallon of water, to which add a sixth of tobacco water. If you set to work earnestly you will not find the task so tedious as you may imagine it to be. We should also fumigate the house once a fortnight when the foliage is dry. One smoking is of little use, for while it may kill the insects it will not destroy the eggs which they have deposited. Keep also a moist genial atmosphere.

CARPET BEDDING (*W. B. T., Notts*).—The best book for your purpose is the "Parks and Gardens of London," by Mr. Cole. It is published at this office, post free 5s. 6d.

CAPE CINERARIA (*Jersey*).—Your plant is a Cineraria, and we think *C. alba*, introduced from the Cape some fifty years ago. It is raised by cuttings taken as soon as they can be had after the flowers fade. They may be inserted in a pot under a bellglass and kept in a cool house or under a handglass.

LILY OF THE NILE CULTURE (*J. K. L.*).—Turn your plants out of the pots now, shake off the soil, divide the stools into as many pieces as retain good healthy roots, and plant them out 2 feet apart in a bed of rich soil in the open garden. Water if the summer prove dry, keep down weeds, and by September you will have a store of fine healthy plants well furnished with dark green foliage, which should then be lifted with very little soil and repotted in soil of two parts loam, one of leaf soil or old hotbed manure, and a half part sharp sand. Let your pots be in proportion to the size of each plant. Use plenty of broken pots for drainage, so as to insure a free passage for water, which give abundantly. To convince you that no fear need be entertained of overwatering we may add that this fine old favourite proves to be one of our best aquatics, and we have now several plants in full bloom well established in a pond under a couple of feet of water.

PRUNING NEWLY PLANTED RASPBERRIES (*Idem*).—The Raspberry canes should have been pruned to within a foot of the base when planted; leave them alone now till autumn. Replace the soil containing the fungus with other that is sweet and wholesome. If you have planted your flowers it is hardly worth while disturbing them now, as, although the fungus will somewhat affect their health, it will not kill them unless it is present in unusual abundance.

SPERMANNIA AFRICANA (*Major-General M.*).—After the plants have flowered you may cut them down and insert the cuttings in sandy soil and place them in a warm, moist, close atmosphere, where they will emit roots, and may then have more light and air. If potted-off and grown liberally they will make attractive flowering plants for next winter's display. After the old plants have made fresh growths an inch long shake most of the old soil from their roots and repot the plants in clean well-drained pots of the same size or a size less than those in which they have flowered. If you do not wish to cut down the plants you must either repot them or give them rich top-dressings and liberal supplies of clear weak liquid manure, soot water being excellent. Fumigate for the destruction, or, what is preferable, the prevention of green fly; or you may syringe them with a solution of Gishurst compound, half an ounce to a gallon of water.

GRAFTING PLANTS (*Idem*).—The easiest plants for you to commence with are perhaps Cactuses. Camellias must be grafted on Camellia stocks, and the plants grafted require to be kept close and moist for some time after the operation.

CUCUMBERS FAILING (*R. M.*).—A heavy sodden condition of the soil, a low temperature with a close moist atmosphere, a very light loose soil, insufficient nutriment, may all be cited as causes of the young fruit of Cucumbers becoming yellow-tipped and dying. If the soil is sound and wholesome, and neither excessively light nor heavy, and the roots are healthy and plentiful, a few waterings of liquid manure of the same temperature as the bed should put matters right; and if the soil is shallow apply a top-dressing of rich old manure and loam mixed in equal parts, and into this secure with pegs a few of the leading shoots, slightly covering with soil the part pegged, so as to induce it to emit roots and thus impart greater vigour to the entire growth.

GERANIUM DISEASED (*A Cottage*).—Cut down the plant, shake much of the old soil from the roots, and repot it in fresh compost, or probably it would recover with more certainty if planted-out for two months. The plant has been overfed, and the soil has become sour during the winter months.

APHIS ON ROSE TREES (*W. Thelgou*).—The answer on page 382 contains

what you require. We repeat part of it:—Boil 4 oss. of quassia chips in a gallon of water for fifteen minutes, and add to it four gallons of pure water, mixing it also with a little tobacco water, and with this syringe the trees.

TIMBER FOR A GREENHOUSE (*A Gardener*).—Some notes on this subject will shortly be published.

MILDEW ON ROSES IN A CONSERVATORY (*J. Huish*).—A cool, moist close atmosphere has probably caused mildew to attack your climbing Roses. Syringe the affected foliage, and immediately dust it plentifully with flowers of sulphur, which leave upon the foliage four or five days, then wash it off with clean water applied with a syringe, and repeat the dusting if the mildew is not quite eradicated. Owing to the cold wet weather your house has probably been kept somewhat close. See that it now has a free circulation of air for some hours daily, applying a little fire heat rather than not open the ventilators, and you will soon have your Roses clad with healthy foliage again.

ROSE LEAVES SPOTTED (*Cuskin*).—The spots are caused by deficient root-action. More manure and water would prevent them.

PROPAGATION OF DAISIES, &c. (*T. M. B.*).—Make a bed of rich gritty soil forthwith in any shaded portion of your garden, such as behind a north wall, building, or fence; divide the Daisies, Polyanthus, and Auriculas, and insert them in it about 6 or 9 inches apart, and after a few waterings you only further care this summer will be to keep down weeds. Let the size of the plants be your guide as to the distance apart to plant the Verbenas; 8 inches is a good distance if the plants are in tolerable condition. Broccoli and Winter Greens may be planted between the rows of early Potatoes if the soil is rich. Take up the Potatoes as early as possible, and do not forget to apply a heavy dressing of manure when the Broccoli and Greens are cleared, such heavy cropping being very exhaustive.

BIENNIALS (*J. Watson*).—This term is applied to plants raised from seed but not coming into flower till the next year, when they usually die. All the plants you enumerate are such, and to term them biennials is therefore correct. It is probably owing to the fact that many of them, as for example Sweet Williams and Indian Pinks, will live longer if prevented from becoming exhausted by perfecting full crops of seed, that they are sometimes included in the list of perennials.

SAVING GLOXINIA SEED (*J. H. B.*).—Give your Gloxinias plenty of liquid manure to induce robust foliage and large flowers, and when the flowers are fully developed let them have plenty of light and air, and water sparingly. Disperse the pollen with a camel-hair brush, and your seedlings will give considerable variety of colour.

PROPAGATION OF ERICAS (*Idem*).—Insert cuttings of the young growth in silver sand upon well-drained peat, and cover them with bellglasses. Azaleas may also be treated in the same manner. Your Cucumber house will answer very well for the purpose. Much care is requisite in keeping the sand regularly moist and in wiping the condensed moisture from the interior of the glasses. The striking of hardwood plants can only be insured by skilled propagators.

CULTURE OF NERTERA DEPRESSA (*A. B. C.*).—This plant answers well in small pots of rich soil in a warm greenhouse temperature. It loves plenty of water while growing freely and perfecting its fruit. We have numerous plants bearing berries abundantly growing in miniature swamps made by mixing rich soil with water in small flower saucers and planting a small portion of a plant in the centre, where it soon spreads over the surface, blossoms, and bears fruit. You have done wrong to put your sickly plants in a cold frame. Adopt our method, and put them in an unshaded place in your vinery. They will thrive admirably in a cold frame when they are well established in their pots.

GRAPE VINE LEAVES UNHEALTHY (*Idem*).—The thin texture of your Vine leaves is a clear indication of imperfect root-action. Formed from the stored-up sap they failed to obtain that supply from the roots which imparts substance, simply because of a paucity of feeders or rootlets, and unless such exist it is quite useless to cover your border in winter. Look to the border. Is the drainage so bad that stagnant water accumulates and kills the roots? Is the soil exhausted? If so apply a heavy top-dressing of manure immediately, and add a few feet of fresh soil to the width of the border if possible. Sound drainage, plentiful waterings, especially of sewage, and heavy surface dressing of manure, will do more good than anything else. Encourage as much lateral growth as you can in order to promote an abundant formation of rootlets, and you will find that the foliage will not become scorched like that of the earlier leading shoots, and thus have a reliable indication that a real improvement is being effected.

BEETLE ON POTATOES (*M. E. Holman*).—It is not the Colorado beetle. Entomologists tell us it is *Adilius sulcatus*, an aquatic beetle that often wanders from the water.

NAME OF FRUIT (*A Constant Reader*).—Winter Greening. The plant is *Iris foetidissima*.

NAMES OF PLANTS (*A Reader*).—We cannot identify from leaves only. (*East Sussex*).—1, *Calamintha grandiflora*; 2, *Saxifraga hypnoides* var. (*Fern Leaf*).—*Buddleia globosa* and *Diplacis glutinosus*; (*R. Ding*).—1, *Adiantum cuneatum*; 2, *Davallia canariensis*; 3, *Pilea muscosa*. (*W. E.*).—1, *Alyssum* (*Königs*) *maritimum*; 4, *Polygala oppositifolia*. (*Prowse*).—*Pyrus*, near *Aria*, but not that species; 2, *Hydrangea* sp.; 3, *Ribes speciosum*. (*W. H. Bibby*).—*Weigela amabilis*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION OF THE SWEDISH TURNIP.

THIS root is one of the most useful in cultivation, and with proper management may be grown upon all soils. Mangold wurtzel has to some extent displaced a portion of the Swede crop, yet for open field feeding, especially upon hill farms and where large breeding flocks of sheep are kept, Swedish turnips still hold their own, and are the principal dependence for sheep in the spring months. When Swedes are to be grown after

wheat or any grain crop and the land contains couch grass, it should be tilled immediately after harvest; but we object to deep ploughing by steam power, as it brings up raw soil, which is often sour and unkind and is also loaded with the seeds of weeds, which cause much trouble and involve additional expense in hoeing and cleaning of the crop of Swedes; but if the land is cultivated by steam power and only moved a good depth without bringing the subsoil to the surface, we have all the advantages of deeply stirring the land without the disadvantages attendant upon deep ploughing. It must, however, depend upon the nature of the soil as to how it should lie during the winter months. If it is light soil, either of chalk, gravel, or sand, it may remain on the level; but in case the land is of clay or strong loam and lying flat, it is best to have it left in ridges of the usual size, the land properly water-furrowed and left as rough as possible. It is a common practice in some counties, particularly in the northern and midland districts, in the case of light land, to plough the land into stretches about 2 feet apart, as it then receives the full benefit of a larger surface exposed to the action of frost and rain.

Very much will depend upon the rotation of crops upon which the land is cultivated, and this will differ in almost every county and district. The course of cropping will of necessity influence the mode of management for the root crop. When the land is free from couch the wheat and other eddishes are left to run the sheep on, or seeded with light grass in order to furnish autumn food for the ewe flock; but in case the land is intended for Swedes no roots of turnips or Swedes should be drawn to the ground for feeding the sheep, because any parts of roots lying about unconsumed if ploughed-in seriously interfere with the Swede crop following. We have noticed in such cases where the remains of roots have been turned in and buried with the plough, although the Swedes were properly manured and cultivated, that the plants would grow very well and produce good-sized bulbs, but that early in the autumn they would die away with a sort of dry rot on the crowns and be quite worthless for keeping, and should be pulled for immediate feeding as soon as the rot was discovered.

Rotation, too, has a great effect upon the growth of Swedes. Many years ago we took to a farm whereon root cultivation had been little practised, and in consequence we could grow capital Swedes without any manure if the land was in good condition in other respects and well cultivated. After a few years this could not be done, and good Swedes could not be grown without artificial manures; and, again, upon the same farm after a long succession of Swede culture we were obliged to give up their growth altogether; for although we could grow as fine crops as before by heavy manuring, yet the roots would not keep during the winter months, even if they were used for cattle or fed-off early by sheep: they possessed but little or no feeding properties, as neither bullocks or sheep would fatten upon them. We partly attribute this to other causes than the continued cultivation and growth of the same root without alternation, because the land was under a very high system of farming, and was in consequence strongly impregnated with ammoniacal manures, which are not favourable for the healthy growth of Swedish turnips unless the land was in very poor condition previously. This is evidenced by the application of Peruvian guano or nitrate of soda in large dressings, as the roots produced will grow with long stems and be sure to decay prematurely.

As a preparation for the culture of Swedes the land should be pipe-drained if lying wet and flat; in fact, upon flat strong land we cannot recommend the culture of this root. We much prefer a crop of mangold to be removed and followed by wheat, barley, or oats according to circumstances. It is true the crop of Swedes may be removed for cattle feeding in the same way, but they do not keep so well in store for any length of time as a mangold crop, nor can they compare with mangold in other respects, for mangold on the same land will produce one-third more weight, and one-fifth more feeding value per acre than Swedes. One of the chief requirements for successful Swede culture is that the land should be fresh in chalk. Cultivators are often deceived in this matter, because, the farm land resting on chalk, they have oftentimes no conception that such land is sour and unkind and may require chalk to grow roots upon it in perfection. It is, however, not enough that the chalk underlies the soil, it must be in active operation on the surface to be of benefit in root culture. We have often heard farmers say, Our land cannot require chalk, for we can plough it up by going a little deeper; but this is a great mistake—it is rubble, it is not chalk. It was chalk originally, but the roots of plants and the action of air and water have robbed it of its lime and left it little better than gravel, and is often called rubble. We have, however, noticed in soils that were entirely out of chalk, all former application having been used up, that when twenty-five bushels per acre of fine-screened chalk were drilled with the manure instead of ashes, Swedes succeeded remarkably well. This practice, even upon the sharpest sandy land subject to weeds, will insure healthy growth of Swedes; but the chalk must be pure, soft, and taken from the bottom of the

pit, the greater the depth the better from which it is obtained. This may in the winter time be carted home, so that it becomes dry and fit for use in due season. Whenever land is quite free from couch, and particularly where large flocks of sheep are kept, it is not desirable to have a naked fallow during the winter and spring, which is the most expensive of all preparations; but we prefer to grow a crop of rye or trifolium to feed-off with sheep, or cut up as green fodder for cattle or horses. The ploughing and drilling the Swedes should take place immediately after the green crop is removed, otherwise in a dry season the land will become dry and unkindly for Swedes. In all other respects it will be better than an old fallow with less damage by fly, wireworm, grub, or other enemies.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour is still in arrear owing to the succession of wet weather, and a considerable portion of the mangold seed is still to be sown; and some of the early-sown crops having been eaten off by the small white slug the land will have to be ploughed and resown. It is getting rather late for the drilling of mangold. We have, however, in some former seasons when delay has arisen sown the seed as late as the middle of June and obtained a very fair crop, sometimes over 26 tons to the acre; but this is not obtained without plenty of manure drilled with the seed and at hoeing time leaving more plants, as they cannot be expected to throw such large bulbs as when early sown; therefore numbers must tell, or the weight per acre will be deficient. The horses are still engaged preparing the land for Swedish turnips; and in all those cases where the root crop is intended to follow rye and trifolium or vetches, the quicker the land is ploughed and sown after the removal of the green crop the better, whether the season afterwards proves either wet or dry.

Hand Labour will now be employed in trimming hedges, particularly the quickset hedges, as these to be kept in the best order should be trimmed twice a year, that is at the middle of June and at Michaelmas; but where the quicksets divide the arable land we require to know for what these hedges are required, for unless bullocks are grazed instead of sheep they are certainly not required, and acting upon this idea we removed all the hedges upon our own farm as well as upon other farms under our supervision many years ago except those required as fences near to public highways and pasture land. We were induced to resort to this sweeping reform in farm management in consequence of the damage which we often observed done by high winds on the lee side of the hedges, where the eddy and whipping action of the wind has done great injury to the corn, especially at and near harvest time, whereas in the open part of the fields, where the wind passes over without any impediment, the damage done has been but trifling. This circumstance, together with the extent of land occupied by fences, decided our mind upon the importance of removing all internal fences upon arable land. After the fences are gone the land can be cultivated instead of being obliged, as is often the case, to make short and costly work in ploughing, in consequence of crooked fences and small enclosures; for even when quickset hedges are of the best and kept neatly trimmed like a green wall in appearance, they then occupy land which will produce food for both man and beast. Fences are, however, advocated by stock farmers as a shelter for sheep both in summer and winter, still it operates badly in some cases, for wherever sheep resort for shelter, whether from the effect of the sun or storms, they leave an undue quantity of manure, which is lost or becomes useless, and this is especially the case when they are consuming costly food like oil cake. Hand labour also consists of hoeing the early-sown mangolds; and although the weather is very unfavourable for the work, yet if it is done whilst the weeds are in their infancy they will die off even in showery weather; but if the hoeing is deferred and the weather should still continue wet and unsettled the weeds will get stronger every day, and will live in spite of being cut up with the hoe. We well remember that in the year 1860, one of the wettest seasons on record, it was quite impossible to kill the weeds by hoeing; we, however, instead of several hoeings, adopted the plan of picking up and heaping the weeds in the field, and for that purpose the women followed the hoers and gathered the weeds. In this case it was the only land whereon roots were grown that was decently clean; in fact it answered the purpose so well that we should not hesitate to do the same this year should the season continue adverse and wet.

The odd horse may now be employed in carting clover for the horses and border grass for the pigs, which eat the hogweed and wild parsley, &c., but to keep the animals in good health and condition it is well to give store pigs a moderate quantity of broken maize. This, after it has been soaked in water for a few days, affords a capital diet in connection with green food of any kind. By this mode of feeding pigs a large quantity of good manure is made, because the roughest grass which may be refused serves to litter the pens, and when the manure outside the styes is allowed to accumulate the dung when removed is found to be very strong, and with earth at the bottom of the styes to absorb the urine, the pens will be found clean and healthy for the pigs. In a wet cold

time like the present the young calves will require great attention not only in their pens and the running-out for a few hours, but also in the manner of giving them milk or its substitutes. We are informed by those who have tried the new method of feeding them by the use of the patented "Lac-Trephoe" or "Challenge" feeder that it answers exceedingly well, and that after two or three days, with a little care and attention, the calves will come and suck the milk from the imitation or artificial teats as soon as the milk is put into the receptacle. This must be considered far better than the calves drinking from a bucket or trough, because there is no way in which they can be prevented from drinking it too hastily; but in sucking from the "Challenge" feeder the milk is taken slowly, mixing with the saliva, and is therefore as healthy and nutritious as when drawn from the cow.

PIGEONS—HINTS TO YOUNG AMATEURS.—No. 4.

I PASS next from Tumblers to Pouters. I do so for many reasons. They form a perfect contrast the one variety to the other. There is much that is pleasing, and in a sense picturesque, which arises from two things brought side by side which are the very opposite in appearance. Church architects of old days understood this. Thus, where in England are the most beautiful church spires? In flat Lincolnshire and Cambridgeshire. The thin tapering spire looks by contrast much the best where the country around is a dead flat. Then look at a poplar tree; a row by a canal does not look nearly so well as here and there one rising among and out far above low round-topped trees. Now the Pouter is the popular among Pigeons, and though very telling on a housetop or at one's feet walking—no, strutting, yet he never to my mind looks so well as among a number of Tumblers, and this because of the contrast. Then a Pouter cock seems always to be very pleased with Miss and Mrs. Tumbler, and coos after them and pays them every attention, while the little ladies prance in front of him on their tiny feet, and, lady-like, liking the attention of the tall fellow, show off at their best, making their neat, round, plump forms still neater, rounder, and plumper; while the Pouter rears himself higher, blows himself out, and, poplar-like, bends and bows with the wind in him, as the poplar bends and bows with the wind playing upon it. If, therefore, you have space keep one or two pairs of Pouters with your Tumblers, as each sets the other off. Then the Pouters do not in the least injure the flying of the Tumblers, as they do not attempt to rise into the air, but take a low sweep or two and then settle on the house, apparently wondering where on earth, no, in air, their little friends have gone. Next, my young amateur, you will not want to spend much money on your pets, for the simple reason probably that you have but a light purse, or those round think it not right to make a large outlay on Pigeons. This need not deter you, as although prize Pouters cost many pounds, yet there is as much pleasure to be had out of somewhat inferior birds, they being still true-bred though of less valuable colour and size. Thus, though a prize bird should measure 18 inches or more from tip of beak to end of tail, yet a Pouter measuring, say, 17 inches, is just as good a pet to the eye, save of a prize-breeder or judge. What are termed the weeds of the loft are the very birds for the young amateur, which also the great breeder is glad enough to sell cheap.

Again, a Pouter should have exact markings, so say the books and so say the judges; but in real truth the correct, the perfectly correct marking is excessively rare, and only made exact for the show pen by certain feathers being plucked out, while the majority of Pouters are very incorrectly marked. The last are the birds to suit you, and at a Pigeon sale sell for very little money. Also there are certain colours among Pouters which are reckoned very inferior. One is what is called mealy, a kind of red with reddish bars across the wings. Fancy, which makes always arbitrary rules, just like Fashion, and rarely has an eye to true beauty, has blackballed this colour; but really a good specimen is a very beautiful colour, soft and pleasing to the eye. Fancy says "No," true taste says "Yes." Fancy and Fashion are often idiotic. Fashion said crinoline was elegant, and tie-back dresses becoming; true taste declared the former was absurd, the latter as absurd. The Mealy Pouter has another virtue besides his colour—he is, perhaps, the best shaped of all Pouters. Among a group I have often singled out a cock Mealy as the best Pouter there for elegance of shape and size of crop. There are other colours cheap enough, such as the blue Chequer, the colour of an ordinary dovehouse Pigeon. This colour is not certainly so bright as the Blue, which indeed is the best of all colours in Pouters; but Chequers often breed Blues, and Blues of value too. There are also the Pouters called Mis-marked or Splashed, Whites with here and there a foul feather. All these may be bought cheaply, while the standard varieties, Blue-pied, Black-pied, Red and Yellow-pied, and Whites are, no doubt, if good very costly. I am writing for the beginner and learner, most likely for those whose purses are not deep or who wish not to be extravagant, neither do they have any prize notions running in the heads.

One thing, if you wish to enjoy Pouters. They must be where you can easily get to them—in some place where you are fre-

quently; and also their box, or boxes, or cages should be about on a level with you as you walk in and out. I knew a small tradesman who, beginning with common Pigeons, gradually achieved fancy birds. He took me to see his first pair of Pouters—a Chequer cock and Blue hen. He happened to have room in an outhouse; he put them in there with nothing better than an old egg chest for their pen. Lowering the upper sash of the widow by day the birds flew in and out straight to their egg chest, which had no front to it. The outhouse was a warehouse in which the master was frequently, and could talk to and pet his birds, hence they became perfectly tame, and would solicit a talk with him whenever he passed in or out. The Pouter is especially the sociable Pigeon; he is positively companionable. While others, such as Jacobins, which I have known kept with them flutter and fly hither and thither when anyone entered, the Pouters were ready and desirous of being noticed. Whether from their form, looking as they do straight into the human face, or from vanity engendered by their crop, for they if in health coo more than any other Pigeons, or because they naturally are indisposed to fly, preferring bowing, strutting, and short wing-clapping flights from one part of their house to another—whatever be the reasons and causes they are most sociable birds indeed; if not they are useless, for a wild Pouter does not inflate his crop, and hence looks only an awkward scared bird. Go near your birds' pens, talk to them, bow to them, especially say "hua, hua," which for generations has been said to them, and this word often repeated makes them blow out their crops, prance about, and show themselves off to perfection. Make them as tame as possible, but never poke at them with stick or finger, but talk to them. In time they will come on your hand or shoulder, and like you to stroke their backs. The tamer they are the better, and it is of little use to keep them in a high loft with flying birds, as you cannot get to them.

You may have heard that Pouters will not rear their young. Some will, but many will not; but all will feed them a few days, then shift them under the Tumblers who have young of the same age. Or, you can do as I have constantly done—rear them, if in summer, by hand; I say if in summer, because in cold nights if the old birds have actually forsaken them they will die, but do not separate them from their parents, and they will often feed them a little and also cover them at night. Soak a handful of beans in a shallow pan; they will swell in a few hours. Before feeding them add a little warm water to the beans; this will make them a suitable temperature. Open the beak with one hand's finger and thumb, and with the other hand's finger and thumb pop in a bean narrow way, and down it will go easily enough; have a little pot of water near and dip their beaks in after they have had a good feed, and soon they will learn to drink. At first five and twenty beans are enough twice a day, then fifty, and on to a hundred. Supply them with small food as they get older—seeds or wheat, and these they will learn to pick up. Children soon learn to feed young Pouters; their little hands are capital for this business. The nest for a Pouter should be large and flat, say 10 inches across by 2 deep. Tumblers for amusement in the air, Pouters for amusement in a building or on the ground. If in the country you can let them have their liberty, but they do well enough in a wired-in place. Let their night place be warm and no draughts possible.—WILTSHIRE RECTOR.

CANARY TREATMENT.

"J. S. C." says, "When the nest of young were about three weeks old I placed by the bars of the cage the materials for another nest, which was speedily made and five eggs laid." Your young birds would then be a month old, and you further say, "when the hen had sat about a week I put the young birds in a separate compartment of the cage, and they were fed through the wires by the cock." At this stage your birds would be five weeks old before they were removed from the breeding compartment where the hen was sitting. The cause of the disappearance of three of the eggs is, therefore, no surprise to us. The young birds should not have been allowed to remain with the hen so long; they interfered too much with the eggs, with their continual squatting and roosting around and partly inside the nest.

Sitting hens vary very much. Some mothers will, when their offspring approach the nest, severely chastise them by suddenly flying from the nest with open beak and extended wings, and chasing and pecking at them about the cage, generally coming off victorious and with a feather or so in her beak, which will in most cases be utilised for renovating her half-down-trodden and damaged nest. On the other hand young birds will sometimes give battle to a sitting hen for mastery of position on the nest, and it is astonishing to see with what pugnacity they will resent the attempted chastisement.

Over such turmoil much discomfort is caused to the hen whilst sitting. Not only does the entire sitting often become spoiled, but some frequently get cracked, and it is not an uncommon occurrence for surprise to be caused through the absence of such eggs, which the hen instinctively disposes of by eating them, shells included.

Let your hen again go to nesting, and no doubt she will, with

quietude and non-interruption, satisfactorily bring forth another brood of young. If you are so fortunate do not let the young remain in the breeding compartment so long. They may be separated from the hen when between three weeks and a month old, and the cock bird will attentively supply them with food through the wires as you experienced over the first nest. At five weeks old young Canaries begin to crack Canary seed, and to encourage them in this seed should be supplied in a separate trough to that containing their egg and bun crumbs. An increase of seed shells upon the cage bottom should guide you in reducing the quantity of soft food until the young feed entirely on the seed. Of course these remarks apply especially to birds when being weaned from one diet to another. When the hen lays her eggs take them away three successive mornings and replace them carefully when the fourth is laid.

If the hen does not go on satisfactorily with her next nest write again to us, detailing particulars, for we think there may be another cause of the eggs being removed from the nest.—GEO. J. BARNESBY.

VARIETIES.

In 1870 the Wrexham Local Board attempted to utilise the town sewage on a farm eighty-two acres in extent, but after two years' experience abandoned the undertaking. In 1872 Colonel Jones leased the farm at a rental of £5 per acre, and purchased for £1600 the farm buildings and other permanent improvements made by the Board. At the close of February, 1877—that is, after five years, Colonel Jones found that after paying his rent and putting aside £5 per cent. on his capital as a sinking fund he had made a nett profit of close upon £1500. Thus sewage farming is profitable when intelligently conducted.

MR. JAMES HOWARD, who has been elected President of the Agricultural Engineers' Association, in virtue of his office becomes a Royal Commissioner of the Paris Exhibition. The Association has unanimously decided not to open the British Agricultural Department at Paris on the Sunday.

In the hop plantations, says the *Farmer's Gazette*, the bine has made such vigorous progress during the past few weeks that much difficulty is experienced by the tyers in keeping pace with the rapid growth; and in some grounds the land is so moistened by the late rains that tying or nidgeting is at a standstill. Meanwhile weeds are also growing apace, and dry weather is much needed that the nidget may be speedily applied for their destruction. The flea is numerous in the Weald of Kent, but flies are scarcely observable.

THE cleaning and disinfecting of the poultry house should be done oftener than semi-annually, but a thorough cleaning-out in early spring is indispensable. After removing all utensils and fixtures—and they should all be moveable—carry out all the dirt and filth that can be swept and shovelled. Then follow with a good coat of whitewash; go over every point of the surface, floor and all. Then clean out all nest boxes, pour a little can oil in the corners, then whitewash them, together with perches and everything in or about the house, and put everything in place again. Now make a fire on the floor, if it be an earthen one as it should, or in an old iron pot or kettle if it is not, and burn half a pound each of resin and sulphur in the house, keeping all doors and windows closed as tight as possible. When the fire is burning well throw some shavings or rags saturated with crude carbolic acid on it, and thus employ the fumes of this best of all disinfectants. When all is thoroughly done open and ventilate the house, and it will be ready for its occupants, and be sweet and wholesome. The house should have such a cleaning-up three or four times each year. It is some trouble, but it will pay.—(*New York Tribune*.)

THE Royal Agricultural Society now consists of 81 life and 72 annual governors, and 2888 life, 4180 annual, and 26 hon. members, making a total of 6637. His Royal Highness the Prince of Wales has intimated his willingness to accept the presidency of the Society for the ensuing year.

A WRITER in the *American Poultry World* says that the effect of sunflower seed in glossing the plumage of fowls that eat them is very soon noticeable. Another advantage in this feed is that breaking the shell to get at the kernel—which they soon learn to do—is useful exercise, and diverts attention in confinement from egg-eating, feather-plucking, and similar mischief of idle hens.

AGRICULTURE will be prominently represented at the Paris Exhibition during the present month. The show of live stock opens on the 9th inst. and continues until the 18th. The show of dogs opens on the 26th inst. and closes July 8th. The total number of entries for the British section of the live-stock Show are—cattle, 101; sheep, 176; pigs, 106; poultry, 378; Rabbits, 10; Pigeons (couples), 18.

THE *American Cultivator* states that chickens require neither food nor drink on the day on which they are hatched. The plan of cramming peppercorns or grains of barley down the

throats of newly hatched chickens is exceedingly injurious. The best food for them is sweet coarse oatmeal mixed into a crumbly paste with milk, and a certain proportion of custard made by beating together an egg with two tablespoonfuls of milk, and "setting" it by a gentle heat. Custard so made is eaten with avidity, and the chickens make rapid progress upon it. Such a preparation is far superior to the hard-boiled egg so often employed, and which is not relished by the chickens. With regard to animal food there is none equal to the natural supply of worms and insects obtained by the hen when she is at large. Small worms or a shovelful of mould containing an ants' nest may be given if chickens are in a confined situation, and will be found far superior to boiled egg, chopped meat, or any mere artificial substitute.

A GOOD harvest is expected in the United States. According to authorities in all parts of the Union the promise of the growing crops throughout the vast and productive expanses of the Great Republic was never more encouraging. From New Jersey to California, from Texas to Maine, every State, with the single exception it is said of Colorado, reports the most brilliant prospects for the yield of every description of food for man and beast, as well as such luxuries as grapes and tobacco. There is an enormous increase of acreage under wheat, and a magnificent crop is anticipated from the great cereal-growing States of Iowa, Kansas, Nebraska, and Minnesota.

UNFAVOURABLE BEE SEASONS.

BETWEEN the years 1860 and 1870 we were favoured with many good seasons for honey—some seven or eight out of the ten. Since 1870 we have had many seasons unfavourable for bees. Last year was one of the worst ever known for bees; it was also unfavourable for farmers. The present season, so far as it has gone, has been worse than last year for bee-keepers, though much better for farmers. The crops of the farmer are most luxuriant and promising, while the stocks of apiarians are few in number and late. Days and weeks have come to British bee-keepers unaccompanied with the blessing of genial warm sunshine. The trials of bad luck in bee-keeping are discouraging to beginners, and are not unfelt by older apiarians who have often been encouraged by the successes of bygone years. Some veterans in practice who have fought many battles without knowing what defeat is have been severely tried and disappointed by their heavy losses during the last few months. This morning's post brought a letter from the north of Ireland (Ballymena) informing me that the writer of it had lost all his stocks, eleven in number, and could not find a hive in that neighbourhood wherewith to begin again.

As the weather is still unfavourable here and hives light, feeding is necessary work in the apiary. Feeding in such unfavourable springs is the safest and most profitable course to pursue. When hives are full of bees and rearing much brood, and perhaps building combs, the bees require a great deal of food to feed themselves, nurse their brood, and keep all the interests of their hives in healthy working order. Owing to the weather being so unfavourable this spring bees seldom visited the blossoms of gooseberries, plums, pears, and apples. The sycamores have not flowered at all in this neighbourhood this season. Beans are now in flower, but few of these are grown in this parish. Humble bees which pierce or tap the flowers of beans are seldom seen here now-a-days, and it is a question whether bees can tap the tubes of bean flowers and get their honey without the aid of humble bees. Beans yield a great deal of honey after their flowers have been tapped. After beans come clover, limes, brambles or blackberries, and heather. These principally have bee-keepers now to look to for honey this year.

Some hives that did not swarm last year will be late in coming to the swarming point this season, and some apiarians will hardly be able to decide whether to let them swarm or be supered. Whichever course be adopted we suggest that the old hives be not kept as stocks for another year. It is but seldom that hives which remain two seasons as non-swarmlers are free from foul brood, and many of the centre combs are loaded with farina. Sugar-fed and sugar-made stocks are incomparably better for keeping than old non-swarmlers. Those who are seeking honey and honeycomb should super their hives now or as soon as they are ready for supering, and at the end of the season drive the bees into empty hives and feed them into stocks; and those who wish to increase the number of their stocks should encourage swarming and take swarms up till the end of June.—A. PATTIGREW.

BEEES.

As none of your correspondents have noticed Mr. J. Robson's remarks at page 885 allow me to do so briefly now. Early swarms this year so early as May 2nd I should consider a calamity in such a year as this. Of course Mr. Robson's country may be singularly favoured. Here a swarm of May 2nd without liberal feeding would have probably perished—in fact both it and the parent hive. All depends upon circumstances whether early swarms

are covetable or not. In forward years I have had swarms (aye, out of "boxes") in April which have done well enough.

Again, there is no doubt that bees are better managed now than they were fifty years ago, not by the ruck of bee-keepers certainly, but by the increased number of careful apiarians which late years have produced; and as for the harvests of honey, I never heard in my boyhood of such quantities produced by single hives as are now not uncommonly yielded. We used to read of Mr. Nutt's success in this direction with utter incredulity, but the marvellous reports sent in to this Journal also by bee-masters of respectable character, whose word cannot for a moment be doubted, have paleled even Mr. Nutt's statements.

As for honey being so plentiful as to be substituted for sugar, it might have been so done in the glut of 1876, but for the fact that sugar is cheaper than honey as well as better in every way for sweetening purposes.—B. & W.

FEEDING BEES.

I HAVE been waiting for other apiarians to give their experience on this subject, but as none have sent it I will detail mine, in the hope that we may gain information by comparing notes. A correspondent (page 868) seems under the impression that the barleysugar used for feeding bees is the same as that sold in the shops, for he mentions it along with toffy, hardbake, &c., whereas it is merely sugar and water and a little vinegar boiled as described in your "Manual for the Many" on bee-keeping. I find it rather troublesome to make, as it requires boiling for a much longer time than "twenty minutes" before it sets, and sometimes it has become burnt. If burnt it is of no use, for the bees will not eat it, and it will deliquesce and drop down into the hive like thick glue.

For feeding bees in warm weather and for giving a large quantity of food for a short time I think syrup is the better, but I prefer barleysugar for feeding them in cold weather and in the spring.

Having had occasion to feed a hive during the winter months I used barleysugar, and I could give enough at one time to last a week; therefore I did not have to disturb it so often, and the bees were never without a supply, for they only seemed to use it as required, and not to store it up. I placed it over the top of the hive, and covered it with a flower pot and piece of quilt.

With regard to the barleysugar requiring moisture to dissolve it, I found the bees settled on it at once and commenced feeding, and did not go outside the hive for water. On the other hand it may be urged that syrup contains too much moisture, and this is not desirable in cold weather.

I make my syrup as recommended by Mr. Pettigrew—viz., a pound of sugar to a pint of water, so that if sprinkled over the bees they can soon get clear of it.—TOM TOWER.

PROSPECTS OF BEE-KEEPERS.

IN your issue of March 7th I concluded a paper with these words, "When the number of hives is complete in any given spring and a large quantity of honey is an object, we should be ready to prevent our bees swarming and make the whole population devote themselves to honey gathering."

I suppose that not one of your apiarian readers would differ from me in this statement, but it is for all that easier said than done. This year, for instance, no amount of provision, be it ordered in the most approved fashion—à la Pettigrew or à la "RENFREWSHIRE BEE-KEEPER"—will induce obedience to our will on the part of our bee friends, certainly not in localities like ours, in such a spring as we are having. Here in Somersetshire the whole country is either actually under water or the ground so sodden with long-continued and excessive rains that not merely honey gathering has been nil, but even breeding has been languid, and in some hives has almost discontinued. The stronger hives have not a single cell of honey sealed up that I can see; none have gone up into supers except for personal accommodation, yet we are surrounded by orchards which have been in wonderful bloom. How is swarming to be prevented under such circumstances? I expect a general sedge-knife or stampede the first sunny morning, and nothing, it seems to me, can prevent it in those stocks which are at all populous.

Let all learners, therefore, in our apiarian school know that in this science, as in all others, there is no rule without an exception. Do what you will, with all your care and provision circumstances must often rule the day; but nevertheless it is quite possible to reduce the apprehended evil to a minimum, and if swarming cannot be prevented its mischief can be very easily neutralised, for very mischievous it would be in such a season to let bees have their way, leading to a multiplication of weak and impoverished hives and paving the way for still further disappointment. I therefore strongly advise the return of all swarms at once to the parent hive where increase of stock is not a necessity. First I would have the swarm temporarily, putting it in the old stock's place; then, after carefully removing from the latter every royal cells (which in bar-framed hives are readily got at), I should at

once restore the stock to its place and set the swarm above it, of course opening all the communications; remove the temporary hive when the bees are gone down, and give plenty of super room. In this way you will have every available bee, and plenty of them, at full liberty to make the most of the precious days or hours favourable to honey gathering which may yet be granted to us this summer. Even in the common or improved straw skep it is generally possible to get at many, if not all, of the royal cells for excision. If any should escape observation, as is likely, the only remedy is to return the swarm every time it issues, destroying the queen mother, who must be caught for the purpose.

Our only hopes for this year as to honey rest now with the white clover and the heather, the latter being beyond the reach of most of us. It is too late for the usual spring supply, which is nearly over. A few really fine days might fill up the empty cells sufficiently to carry on the bees to the time of clover, but I am far from sanguine that this year will prove much less disastrous than the last, which was certainly one of the worst in my large experience of bad seasons. Bee-keepers need to have a hopeful temper in view of all this disappointment so frequently recurring.—B. & W.

REMARKS.

29th.—Wet morning; dull but fair rest of the day.
30th.—Fair morning, rather finer during the day, but cold.
31st.—Fine bright sunny day.
1st.—Misty, very dull in morning, fine and sunny in afternoon, fine evening but cold.
2nd.—Cold and cloudy but dry day.
3rd.—Dull hazy morning, bright afternoon, fine evening.
4th.—Heavy rain in early morning, and very heavy showers during the day; fine evening.
A moderately fine but cool week, with drenching showers on June 4th.—G. J. SYMONS.

COVENT GARDEN MARKET.—JUNE 5.

OWING to the dull weather outdoor Strawberries have not made their appearance this week as was anticipated, consequently forced fruit is in demand. English Pines will now sell better, the St. Michael's fruit coming irregularly and showing a considerable falling-off. Trade somewhat improved.

From observations taken near London during forty-three years, the average day temperature of the week is 72.2°; and its night temperature 60.5°.

GROWING GRAPES IN UNHEATED HOUSES.

CONSIDERING the immense popularity of the Vine and the great importance every person attaches to Grapes, it is surprising that many who cannot afford to erect expensively heated structures in which to grow them do not resort oftener to cultivating them in unheated houses. I do not think many can be aware how well Grapes can be grown under glass without fire heat, or we should hear less about so many rows of hot-water pipes having to be placed in houses in which Grapes have to be cultivated, and all the particulars of temperature and firing so rigidly adhered to in many cases. Contrary to this, I may say that the Grapes on Vines in a house here with no means of heating it are as fine as any in the heated structures. According to appearance some bunches of the Black Hamburgs, I should say, will weigh when ripe close upon 3 lbs., and by the month of September I have no doubt they will be as well ripened, and perfectly finished in every respect, as those grown in heated houses. Of course, early Grapes cannot be grown in unheated houses, but to have fruit ripe in August it can be done perfectly, and to have a good houseful of Grapes then that will last for the next four months, and that, too, without even spending a halfpenny on fire heat, is worth considering. I hope I am not understood to say Grapes can be grown better in unheated than in heated houses, but I hold that autumn Grapes can be grown as well in the one as the other; and that in many instances fire heat is applied quite unnecessarily in summer Grape growing, and in other cases they are not grown at all, because it is supposed there is not heat enough in the house, which is generally a delusion.

An unheated vinery should be constructed on ordinary principles. It is of considerable importance that its aspect is due south, and sun heat must not be obstructed from it. The border should also be carefully made either outside or in; but do not expect success if work of this kind is done in a careless manner with the idea that as the house is not heated it is not worth while spending much time in properly preparing for the Vines. It is just attention of this kind that will compensate for the want of fire heat and render success more certain. June is the best month in all the year in which to plant Vines in unheated houses. Planted earlier, they are slow in starting into growth; later, they have not time to establish themselves thoroughly before the autumn and winter.

The details of planting Vines have been given so fully in previous numbers of the Journal that I need not go into the matter fully here, but I may say that only good, strong, healthy Vines should be planted. Eyes put-in in February and grown 4 or 5 feet high now are better for planting than last year's canes. After planting they should be shaded slightly for a few days if the sun is strong, and little or no air should be admitted until they show signs of growing. Healthy young plants soon do this; in fact when carefully planted they grow on without ever receiving a check. A moist atmosphere favours their growth at all times.

No. 908.—VOL. XXXIV., NEW SERIES.

One of the most particular points to attend to in growing Grapes in unheated houses is ventilation. This is a most important matter, not only the first year after the Vines have been planted, but in all subsequent years, as one of the chief requirements is to secure as much natural heat in the house as can be had. In giving air in the morning it should never be too much increased until the temperature is rising rapidly. We never adhere very strictly to figures, but, roughly speaking, air may be admitted when the heat is 70°, and no more should be admitted than will keep it from rising above 90° or falling below 80°. During March, April, May, and June the house should always be closed early in the afternoon before the sun goes off it and when the heat will rise to 85° or 90°. When the Grapes commence changing colour more air may be admitted, and the house need not be closed so early when the weather is favourable. Vines grown in an unheated house do not require so much syringing as hothouse Vines, as they are not so liable to become infested with insects.

In moist localities the most difficult matter connected with this kind of Grape culture is keeping the fruit after it is ripe in October and November. This, however, is not without an easy remedy, as the bunches can all be cut, the ends of the laterals on which they are hanging being inserted in bottles of water and placed in a dry room, where they will keep soundly for months.

Black Hamburg, Royal Muscadine, Buckland Sweetwater, Black Alicante, Lady Downe's, and indeed nearly every kind of Grape excepting Muscat of Alexandria, succeeds in unheated houses. Should any of your readers be interested in these notes I may say they can be verified, as last autumn the Journal mentioned approvingly the fine Grapes Mr. Harrison Weir exhibited at South Kensington from an unheated house.—A KITCHEN GARDENER.

SPRING FLOWERS.

THERE is a very general but erroneous impression that spring gardening is an elaborate, costly, laborious process, and therefore not to be attempted by anyone of limited means or restricted labour power. An earnest wish to dispel this error prompted the writing of this.

Beds of bare earth in conspicuous positions are just so many unsightly scars which it is desirable to get rid of. Bad as they are in winter, it is in spring when all wild growth arises into beauty that they become doubly offensive, and a garden thus neglected repels—almost disgusts—at the very time it ought to attract and delight. This is a test to which I have before called attention; it is so valuable as to be worth keeping prominently in sight. Amid all the freshness and brightness of spring does your garden gain by comparison with its wild surroundings? To its superior tone of refinement is there then added those of richness, fulness, warmth? Or as you turn to it from the enjoyable contemplation of wild flowers are you sensible of some void—something or many things wanting? Instead of Lilacs, Thorns, Laburnums, Azaleas, Kalmias, Andromedas, Weigelas, Ribes, Rhododendrons all bursting into beauty and affording a succession of gay blossom till advancing

No. 1350.—VOL. LIX., OLD SERIES.

summer brings her Roses to form the next link in the floral chain, do you find heavy monotonous masses of dull greenery—Laurel, Box, Yew, or an ambitious pinetum—an assemblage of Conifers without one spray of deciduous growth or one flowering shrub to lend variety, freshness, and colour? Or instead of beds gay with their peculiar spring flowers—bright masses of pink, blue, yellow, white, purple—are your beds bare as when stripped of last summer's plants, or perchance at best containing only some dwarf evergreen shrubs? If so, your garden is not as it ought to be, for if you can afford to plant shrubs at all most of those which I have named are comparatively inexpensive, and are all so beautiful as to render the work of selection by no means easy.

It is not upon the shrubs that I must now dwell, but the flower beds; for the season for raising a stock of plants for next spring is fast approaching, and I hope to induce many professional gardeners, as well as amateurs, to adopt the easy and simple method of doing so which I have now to set before them once more. Now, I suppose no one would say that the raising and planting a bed of Cabbages was a process so difficult as to render a Cabbage an expensive luxury. On the contrary, it is so easy that a good Cabbage bed is the boast of every cottager. The spring flowers with which I am able to make gay as many beds as I please are raised and cultivated precisely like Cabbages. You need not devote much space to them all at once. Take any little odd patch of garden border, dig it, make it fine, make shallow drills, sow the seeds; when the seedlings are large enough prick them out a few inches apart, give a little water, keep down weeds, and transplant to the flower beds in autumn immediately after the summer plants are cleared away. This is the entire cultural process; no glass, no artificial heat, and certainly not very laborious.

The first seed to sow is the Forget-me-not, and the sort which I find answers best for large masses is the lovely blue one, *Myosotis sylvatica*, and its white variety *alba*; both must be sown in the second or not later than the third week in June, so no time must be lost in ordering the seed, which is very small, and a sixpenny packet of each will suffice for a large garden. If you want variety and very early flowers you may add *M. dissitiflora*, a fine blue, costing a shilling a packet; but I am quite content with *sylvatica* and so are the bees, which haunt the beds by hundreds on every sunny day. Next in order of sowing is the deep pink *Silene pendula* and *S. pendula alba*, to be sown not later than the third week in July. Then come the pretty little Soapworts, *Saponaria calabrica* and *S. calabrica alba*, forming charming dwarf masses of pink and white. They are sown the second week in August, and at the same time sow some Golden Feather *Pyrethrum* for an edging to the pink *Saponaria*. The seed of all these, including both sorts of *Silene*, costs sixpence a packet, and you are not likely to require more than a packet of each. At the end of August we must sow the delicate blue *Nemophila insignis*, the purple *Collinsia grandiflora*, and the yellow *Limnanthes Douglasii*. We shall therefore require ten packets of seed at a cost of 5s. if we have the whole of my selection.

Let me add one word as to soil. Many hardy plants are killed in winter from being planted in heavy adhesive soil; it ought therefore to be an imperative rule to make the soil light and open with plenty of gritty matter, and to raise the beds well above the level of the surrounding surface.—EDW. LUCKHURST.

EARLY VEGETABLES.

On the 3rd of June I gathered our first Peas from the open from William I. and Dickson's First and Best, being eleven days earlier than last year. For the most successful way to grow early Peas see page 132, Feb. 14th, 1878; see also what an occasional correspondent has to say at page 168, Feb. 28th, 1878. He says it is a delusion to grow Peas as described at page 132; if so, why should he grow his Little Gem in the orchard house? I have had the pleasure of seeing his Little Gem Peas growing in his orchard house, and certainly they were the most perfect delusion I have ever seen in Pea-growing. By growing Peas as described at page 132 they do not require to be rolled in; they do not require to be coated with red lead to keep off mice; when breaking they require no coal ashes to keep off slugs; and lastly, they do not require three strings of worsted to keep away the sparrows.

I on the same day dug the Alma kidney Potatoes from the open. I find this variety twelve days earlier than Rivers' Royal Ashleaf, but the earliest of all kidney Potatoes is to be the Early Bird. I have not proved this variety; it is a beau-

tiful-looking Potato. The whole of the stock has passed into the hands of Mr. Turner of Slough. All those who desire to have a beautiful-looking and a good keeping Potato should think of the Early Bird whenever it is sent out.—R. NISBET, *Aswarby Park Gardens, Folkingham.*

RULES FOR JUDGING ROSES.

I HOPE I am not premature or intrusive in venturing to offer a suggestion that the admirable and comprehensive code of rules lately compiled under the authority of the National Rose Society for the guidance of Rose judges, including well-drawn definitions of the constituent properties of (1) a bad, and (2) a good Rose, might very advantageously for the public find a place in all horticultural papers, and *a priori* in our Rose Journal.

I believe I am right in saying the whole subject was taken into consideration at the meeting, when the list of judges, amateur and nurserymen, was pricked off for the metropolitan and provincial National Rose shows, after their names had been previously submitted to the General Committee for their selection. Now I have always consistently opposed this mode of proceeding for reasons already given in these columns, but chiefly because I consider it a work of supererogation and but too likely to stir up troubled waters where for several years an unvaried calm has most agreeably prevailed. I hold, however, and many of my friends agree with me, that it is an entirely different matter to issue a code of rules for the guidance and enlightenment of young amateurs and gentlemen's gardeners (the latter, I will do the justice to say, are always ready to lend a hand where their services are required), who essay to try their prentice hands as Rose judges at country exhibitions; and for the encouragement of so useful an object, where so much doubt and ignorance prevail, publicity should be given as wide and as speedily as possible.—THE HEREFORDSHIRE INCUMBENT.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

THIS useful Society held its ordinary monthly meeting on the 4th of June in St. Andrew Square, Edinburgh. About a hundred members were present. The President occupied the chair. After admitting twenty-three new members Mr. Hugh Fraser gave his results of *Rhododendron* hybridising, described shortly the history of the plant, and spoke of its introduction at different times into this country. He named the few varieties that existed in 1830 compared with the numbers that are now in commerce, all the products of the meagre materials at command nearly fifty years ago. He detailed some of our finest specimens, giving their parentage, and stating how they were crossed.

Mr. J. Spiers, schoolmaster, Haddington, next read a paper on the history of the Haddingtonshire Ancient Fraternity of Free Gardeners. Mr. Spiers said that the minutes, proceedings, and members of this fraternity are correctly recorded since the 16th of August, 1676, and there are traces on the minutes that this body must have existed for a much longer period. As far back as 1774 monthly meetings have been held, and previously to that meetings were held four times a year. In 1671 prizes were offered for Carnations, and competitions have taken place each year since. The public spirit which has always characterised this Society was abundantly proved by Mr. Spiers quoting extracts from minutes of the resolutions passed from time to time. Both gentlemen were thanked for their communications.

Messrs. Dickson & Co. exhibited *Rhododendron Broughtonii superba*; T. Methven and Sons, *Rhododendron Cinnabarina*; John Carson, Miles' Spiral Mignonette; Mark King, Scarlet East Lothian Stock. The following awards were made by the New-Flowers Committee:—Ireland & Thomson, *Gloxinia* Mrs. Smart, commended; and Petunia Craigleith Beauty, certificated. Dickson and Co., fancy Pansy Hugh Fraser, certificated; Memento and Empress, commended. Downie & Laird, fancy Pansies Lady Clerk, Lady Falmouth, and Mrs. Wolfe Murray, certificated; Lady Hay and A. McLeod, commended.

VILLA GARDENS.

ENCLOSURES irregular in shape and limited in size are commonly attached to suburban residences. A type of these is represented in the accompanying plan (fig. 67), which with certain modifications is applicable to other plots that may vary somewhat in size and outline from the figure submitted. The length of the present enclosure is 136 feet, the width at the widest end next the house being 70 feet, and at the narrow end next the road 58 feet. This unequal-sided oblong strip is so narrow that I have made no attempt to take the path from the gate

to the front door along either side, but have made it an important feature of the garden by taking it in graceful curves

prevent any overlooking of the garden from the gate. The house and south side of the north wall may be turned to account for Tea Roses and climbing plants. The nooks, F F, for a fernery, are of course intended to be shaded by the trees and shrubs. The sides of these nooks should be raised high and steep with rocks and roots mingled with soil, plenty of pockets and ledges being made for the Ferns. The scale is one-twentieth of an inch to a foot; and as the boundaries of the garden are so peculiar, all four sides being unequal, and only one corner being a true right angle, its form is not a common one, and the design could not be adapted to another oblong without, as before observed, some modification. If it were an indispensable necessity that the path from the gate to the front door should not overlook the garden I would put the gate at the north-east corner and make a sunken path inside the north wall, throwing up a high narrow bank along the other side with a dense growth of shrubs along the top, and Ferns and trailers upon the side.—EDWARD LUCKHURST.

attention at the same time. In company with Mr. Crehan, head gardener at Minella House, we visited yesterday the gardens

THE STRAWBERRY—SYSTEMS OF CULTIVATION.

No preparatory observations are necessary to enlist the sympathy of the general reader, whether professional, horticultural, or amateur, while endeavouring to sketch out a more enlightened and successful system of cultivation than generally prevails for this popular, easily grown, and delicious fruit. This has been partially done by an intelligent correspondent in your issue of the 1st inst., with whose object I agree, while with his system—that of preliminary growth in thumb pots—I shall immediately state my reasons for differing. While doing so I cannot do better than sketch out briefly four systems of growth and methods of propagation, any one of which has many points to commend it.

1, By placing small pots underneath the runners at the proper time, and causing the future young plants to root into them by pegging-down or otherwise until the roots are established. This is convenient, inasmuch as after cutting the runner away from the old plant you have your future young one established. But in practice, and for general adoption on a large scale, it has the following disadvantages:—

a, It requires an immense number of small pots and an immense amount of spare time to do the potting, &c.

b, During hot weather, as one is pretty certain to have at that time, half an hour's very hot sun will kill outright a young tender Strawberry plant, even if rooted, and leave it worthless.

c, As vigorous growth is essential from the commencement (if one is not to wait for a second or third year before having a full crop), the growth is generally stunted in small pots; in fact, "caged, cabined, and confined." I believe the system would only commend itself to amateurs having sufficient time to devote to wooing success in watering, feeding, and watching, and who make Strawberry growth a specialty.

2, By lifting the young plants after being rooted naturally into a mulched or previously prepared space between the drills or beds with a trowel, and arranging them in suitable lines where they are to remain. This is perhaps the most convenient, certain, and expeditious system, and entails the least amount of care or trouble—an important consideration at this time of the year when flower, vegetable, and fruit gardens, orchard house, vinery, greenhouse, stove, &c., all require

and grounds attached to the now stately renovated ancestral residence of Captain Moore, M.P., Barne House, near this town, and among very much I should be tempted to digress to notice were some beds of the finest and healthiest-looking Strawberries it has been our satisfaction to see, and grown as above indicated.

3. Mr. Crehan, already mentioned, gives a preference to the following system after many experiments:—Cause your intended young plants to root into a loamy sod from which a portion of the clay has been shook, cut diamond or square shaped, and of only a few inches dimensions, which can at your leisure be transferred to the beds or lines where they are intended to fruit.

4. I may notice what has been called the American system. It consists in the gradual renovation at intervals of the beds, or, better, of the drills, by manuring or otherwise preparing the spaces between and allowing the future young plants to root into the same, then wholly removing the old ones. This has the recommendation that a young stock is maintained, the ground is all changed ultimately, and what is of much moment to those limited in space, the same ground may be constantly used, and saves all the time that would be expended in making new beds.

These observations would be incomplete without saying something of soil and situation. All soils will grow the Strawberry, but the least desirable would seem to be a rich deep one containing a large per-centage of decomposing vegetable matter. In such the roots descend deeply, and you have a splendid crop of leaves and tall flower stems but no fruit, except something poor and small and of very inferior flavour. One has only to observe that some of the finest berries are produced near the gravel walk and in comparatively shallow soil where sun and air—which for flavour are indispensable—have full influence and effect.—W. J. M., *Clonmel*.

MANCHESTER NATIONAL HORTICULTURAL

EXHIBITION, JUNE 7TH TO 14TH.

SUCH is the title of the summer Show of the Royal Botanical and Horticultural Society—a term which, as regards the size and quality of the Exhibition, it merits, and also because nurserymen of national fame are admirably represented in the Royal Botanical Gardens at Old Trafford. Mr. B. S. Williams, Messrs. Rollisson and Son, Messrs. Lane & Son, Messrs. Standish & Co., Mr. Richard Smith, and Mr. Anthony Waterer all arrange collections of great value, and which contribute in an important manner to the success of the Exhibition. The amateurs' classes are occupied almost entirely by local exhibitors, the most notable exception being Mr. Pilgrim of Cheltenham, and right well do they sustain the horticultural reputation of the manufacturing districts. When Mr. Shuttleworth stages his unrivalled specimens, and Mr. O. O. Wrigley and Dr. Ainsworth bring out their magnificent Orchids, a treat is afforded to the public of no ordinary value.

What week is an historical festival in the Manchester district, and high holiday is kept by all classes of the community. Thus it is that the Society opportunely adopt the festival, to speak paradoxically, as the fixture of their principal shows, for a fixture it is, yet necessarily moveable. It is more than ten years since Whitsuntide has occurred so late as this year, and on this account—the lateness of the date—the Exhibition to some extent suffers. The bulk of Azaleas is over, many hardwooded plants have lost their freshness, and the magnificent Roses of Messrs. Turner and Paul finished their season's career at South Kensington during the closing days of May. Yet notwithstanding the absence of those marvellous specimens the Manchester Show is an excellent one, the Orchids alone being worthy of a journey from one end of England to the other by those wishing to see by far the finest display of these gorgeous plants that has been arranged at any exhibition this year.

The principal collections of plants are arranged in the large conservatory, a long span-roofed structure with lofty sides. The only entrance is at one end, the opposite end being occupied by the amateurs' collections of twenty plants in flower. The sides of the building are furnished by collections of Palms, Ferns, and ornamental-foliated and flowering plants in competition, and in front of these are the Orchids. Down the centre is a table containing fruit and bouquets at the end next the entrance, the remaining portion being occupied with miscellaneous collections of plants from Messrs. Williams and Rollisson, elevated above which are, forming a central row, the competing collections of Dracænas from those nurserymen. The effect of the building when viewed from the entrance is extremely rich and imposing; the specimens also well bear individual examination. First to arrest attention are the

ORCHIDS.—Three classes are provided for amateurs and two for nurserymen, the prizes offered amounting to £140 exclusive of the Veitch memorial medal and prize of £5. Although the

nurserymen, Messrs. Williams and Rollisson, exhibit collections of great merit, they are not by any means equal to the splendid contributions of the amateurs. The collections of O. O. Wrigley, Esq. (Mr. Hubbersty, gardener), and Dr. Ainsworth, who are placed first and second respectively in the class for fifteen plants, are magnificent. Mr. Wrigley's plants consist of *Masdevallia Lindeni*, about 8 feet across and bearing perhaps two hundred fine flowers; *M. Harryana*, nearly as large and very rich; *M. sanguinea*, still richer; *Thunia Marshallii*, nine spikes, fine; *Vanda suavis*, twelve spikes, very vigorous; *Calanthe veratrifolia*, fifty spikes, a mass of purity, 4 feet high and more than half that in diameter; *Cattleya Warnerii*, fourteen handsome flowers; *Dendrobium Schroederi*, 2 feet across; *Saccolabium guttatum giganteum*, four splendid and finely spotted racemes; *Odontoglossum vexillarium*, a compact healthy specimen with between sixty and seventy flowers and buds; *Cypripedium niveum*, 2 feet in diameter and forty flowers; *C. Veitchii*, one of the most chastely beautiful of the genus, has ten flowers; *C. villosum*, *Anguloa uniflora*, and last, but not least, *Anguloa Clowesii*. The foliage of this remarkable specimen is nearly 2 feet long and 6 inches broad, and has a spread of nearly 4 feet, and beneath it are quite fifty rich golden flowers. Fine as this specimen undoubtedly is, and awarded as it was the "Veitch memorial prize," it is certainly not the finest Orchid in the Exhibition. That honour we learned was awarded under a misapprehension on the part of the Judges, that the prize was intended for the best plant in the winning collection. The schedule, it must be added, is not so clear as is desirable in regard to this prize, for it is there made a separate class (39), while the prize was awarded to a plant in Class 5. The plant that on its merits ought to have had the high honour in question was a marvellous specimen of *Vanda suavis* belonging to Dr. Ainsworth in the second-prize collection. This plant is 4 feet high and nearly the same in diameter, is in superb condition as regards health and luxuriant foliage, and has fifteen spikes and about 120 fine flowers, and is altogether a grand example of culture. Other plants in this collection are *Oncidium spheculatum*, 6 feet high and 4 in diameter; *Cattleya Mossiae superba*, 2 feet across, forty grand flowers; *C. Skinneri*, twelve splendid flowers; *Masdevallia Veitchii* and *Saccolabium præmorsum*, nine richly spotted racemes, very elegant; *Aërides virens*, twelve, and *A. Schroederi*, seven spikes; *Vanda tricolor Ainsworthii*, five spikes, very rich; and *V. Dennisonii*, two spikes of waxy flowers; *Phalænopsis amabilis*, five spikes; *P. grandiflora*, a splendid mass, 3 feet high and 2 in diameter; and *P. Lüddemanniana*, 18 inches across and about forty flowers; and *Lælia purpurata*, a luxuriant plant with ten spikes. Collections such as these are never seen in London, for both of them are superior to that staged by Mr. Hubbersty when he won the £50 prize at the Westminster Aquarium three years ago. Joseph Broome, Esq., Didsbury (Mr. Williams, gardener), has the third prize for smaller but well-flowered specimens. In the class for nine plants the two redoubtable exhibitors first named have the same positions as before, and with similarly splendidly grown plants—indeed duplicates in a great measure of the plants above named.

In the class for six plants, from which exhibitors in the previous classes were excluded, Mr. Bolt, gardener to W. Turner, Esq., Winsford, has the premier position with *Cattleya Mossiae*, 2½ feet across, very dwarf, and having forty beautiful flowers; *Dendrobium Bensoniæ*, a floral mass 18 inches high, and about the same in diameter; *D. Schroederi*, six racemes; *Lælia purpurata*, three spikes, twelve flowers; *Cypripedium caudatum*, seven spikes, three flowers on each, wonderfully fine and vigorous; and a richly coloured and excellent variety of *Odontoglossum Alexandræ* with two tall and massive spikes. Mr. Bruce, gardener to J. Fildes, Esq., Stretford, is placed second. He stages three *Dendrobiums*—*nobile*, *Schroederi*, and *Bensoniæ*; *Vanda tricolor*, *Lælia purpurata*, and *Cattleya Mossiæ*, all in admirable condition. Third honours going to Mr. Vickers, gardener to J. Heywood, Esq., Stretford, for a highly creditable collection. *Cattleya Warnerii* in this group has strikingly beautiful flowers. The first prize for the best specimen Orchid in flower was awarded to Mr. Bolt, gardener to W. Turner, Esq., for *Saccolabium præmorsum* with six racemes, five of them being 18 inches in length, the flowers being in excellent colour.

Deserving also of prominent notice are the nurserymen's collections of twenty and twelve plants. Mr. B. S. Williams secures the premier prizes in both classes. Formidable, however, as these collections are, Messrs. Rollisson are close seconds, both firms exhibiting remarkably well. In Mr. Williams's collection we noticed *Cattleya Warnerii*, six splendid flowers; *C. Mossiæ superba*, 2 feet across, twenty flowers, very fine; *C. lobata*; *Dendrobium Bensoniæ*, *thyrsoflorum*, and *nobile*, fine; *Odontoglossum Roezlii*, *vexillarium*, and *Alexandræ*, very fine; *Vanda tricolor insignis*; *Oncidium crispum* and *sarcodes*, both good; *Masdevallia Harryana*; *Lælia purpurata*, three grand flowers; *Cypripedium niveum*, nearly 2 feet across, fifty flowers, excellent; *C. barbatum superbum*, twenty flowers, and *C. caudatum*; *Epidendrum vitellinum majus*, nine spikes, very bright; and a very fine example of *Orchis foliosa*. Messrs. Rollisson's:—*Oncidium crispum*, 5 feet high, fine; *O. flexuosum*, and *O. sessile*; *Odontoglossum*

hastilabium; *Lælia purpurata*, twenty flowers; *Epidendrum prismatocarpum*; *Vanda suavis*; *Brassavola Digbyana*, strikingly fringed lip, rarely seen at exhibitions; *Anguloa Clowesii*, twelve flowers; *Cattleya Mossie*, splendid blooms; *Dendrobium Falconeri*, fifteen handsome flowers; *D. suavisimum*, very rich; *D. Devonianum*, 2 feet in diameter, 3 feet high, densely laden with fringed flowers; *Orchis foliosa*, twelve spikes; *Masdevallia Harryana*; and *Cypripedium caudatum*, twelve flowers; *C. barbattum grandiflorum*, fifteen magnificent flowers; and the finest example of the lovely *C. spectabile* that has been seen during recent years. The mass is trained in the form of a half globe, the fifty or sixty fine flowers being arranged just above luxuriant foliage; it is quite a model example of this charming and easily cultivated terrestrial Orchid. The collections of twelve plants arranged by the same exhibitors are similarly fine, the sixty-four plants in the two collections forming a brilliant fringe to the Ferns, and extend nearly the entire length of the building.

NEW PLANTS.—These are arranged by Messrs. Williams and Rollisson, who are awarded prizes in the order named. Mr. Williams exhibits a fine specimen of *Phyllotænium Lindenii* and a still finer example of the distinguished Tree Fern *Cyathea Burkei*; *Phychosepma rupicola*, a grand Palm; *Cycas media*, the stately and massive *Geonoma Seemanii*, *Kentia Mooreana*, an admirable example of a valuable Palm; *Microlepia hirta cristata*, a fresh and elegant Fern; and *Crotons Prince of Wales*, a brightly coloured spiral-leaved variety, and *Queen Victoria*, but not so richly coloured as we have seen it—an admirable group. Messrs. Rollisson's new plants consist of *Cyphokentia macrocarpa*, a distinct Palm of commanding appearance; *Dracena Goldieana*, and a fine example of the stately *D. Gladstonei*; *Crotons Queen Victoria* and *Rex*; *Grevillea filicifolia*, very free and elegant; *Tillandsia caracasana*, much marbled; *Cyathea Burkei*; *Alsophila Inrayi*, very distinct; *Anthurium Laucheanum*, *Erica Dennisonii*, and *E. obbata exposita*. This is a splendid variety with large white bells perfectly smooth and glassy, which adds considerably to its value; it should have a place in all collections. Both of those firms also stage many new plants in their extensive miscellaneous collections. They also compete in the nurserymen's class for ten *Dracenas*, and here again stage several new varieties. In this class Tooting beats Holloway with excellently grown and finely coloured examples of *Goldieana*, *Baptistii*, *Rebecca*, *amabilis*, *metallica*, *Nitzschneri*, *fine*; *Salmonia*, *Imperator*, *Recurva*, and *Regina*. Mr. Williams's plants, which are a shade smaller, but in no other points inferior, are *terminalis alba*, *Robinsoniana*, *Frederickii*, *Baptistii*, *Berkleyi*, *Imperator*, *ferrea grandis*, *amabilis*, and *Goldieana*. We could not fail noticing the superiority of those varieties over the much larger plants staged in the amateurs' class by O. O. Wrigley, Esq., Joseph Broome, Esq., and Lord Hill (Mr. Gratt, gardener)—fine healthy plants, but sombre in comparison with the newer and smaller London specimens. In the class for *Crotons* Mr. Williams wins first honours, also with varieties of recent introduction—namely, *Queen Victoria*, *Veitchii*, *Andreanus*, *Prince of Wales*, *Splendidus*, and *Disraeli*. Messrs. Cole & Son, Withington, have the second prize in this class.

In the amateurs' class for six new and rare plants in or out of flower Mr. Shuttleworth has an easy triumph with *Ixora regina*, 3 feet in diameter, fine; *Croton picturatus*, *Aralia elegantissima*, 3 feet high and through; *Croton Disraeli*, *Gleichenia rupestris glaucescens*, a fine specimen 4 feet in diameter; and *Nepenthes Hookeriana* with leaves almost white, but having a rather sickly appearance.

STOVE AND GREENHOUSE PLANTS.—These are also chiefly arranged in the conservatory. In the class for twenty plants in flower T. M. Shuttleworth, Esq., Howick House, Preston, is placed first, and E. Pilgrim, Esq., Cheltenham, second. It is no easy matter to stage twenty plants in flower without having to include some specimens of only moderate merit. Amongst Mr. Shuttleworth's plants we noticed *Pimelea mirabilis*, 5 feet through; two large pink *Azaleas*; *Lapageria alba*, fine plant but flowers not expanded; *Hedera fuchsoides* and *tulipifera*, *Bougainvillea glabra*, *Allamanda nobilis*, splendid blooms; *Dipladenia Brearleyana*, twenty flowers; *Franciscoea confertifolia*, *Acrophyllum venosum*, *Erica tricolor elegans*, *Dracophyllum gracile*, *Aphelexis macrantha rosea*, 5 feet in diameter, very good; *Anthurium Scherzerianum*, large and fine; *Ixora coccinea*, and *Statiea profusa*. The last-named plant is the most effective in the group; it is nearly or quite 6 feet in diameter, the flowers being in splendid colour. Mr. Pilgrim's plants are more irregular in size, but the group contains several meritorious specimens, but some of them appear rather drawn as if by having been retarded; yet, notwithstanding, Cheltenham runs Preston rather closely.

In the amateurs' class for sixteen plants, eight foliage and eight in flower, the collections are excellent. E. Pilgrim, Esq., wins the premier position. The flowering plants are a beautifully fresh *Stephanotis*, a very fine *Anthurium*, *Aphelexis macrantha rosea*, *Ixora Williamsii*, a plant with twenty grand heads of flowers; *I. Pilgrimii*, very bright; *Erica tricolor impressa*, 4 feet in diameter, very fresh; *Hedera tulipifera*, and *Clerodendron Balfourianum*, a perfect globe $\frac{1}{2}$ feet in diameter. The foliage plants are *Phormium tenax variegatum*, two *Crotons*,

three large Palms, a fine Cycad, and a *Gleichenia*—all large and admirably grown specimens. H. Samson, Esq., Bowdon, is a close second. *Ixora Colei*, *I. coccinea*, *Allamanda grandiflora*, and especially *Dipladenia amabilis*, are remarkably fine; and excellent also are the fine-foliaged plants. J. Rylands, Esq., Stretford (Mr. Smith, gardener), was placed third with a collection of great merit. The nurserymen's class of fifteen stove and greenhouse plants in flower is not so well represented as the amateurs' classes. Messrs. Cole & Sons, Withington, had the premier position, but, excepting the large *Azaleas*, the specimens are not noteworthy. They are also placed first in the nurserymen's class for *Ericas*, and Mr. Pilgrim has the chief place in the amateurs' class; both collections contain a few good specimens, but the majority are somewhat drawn and not well furnished at the base. In the amateurs' class of twenty plants in or out of flower J. Rylands, Esq., stages a collection containing many excellent plants, and was awarded the first prize. A grand example of *Nepenthes Hookerii* in this group attracts considerable attention; it is very vigorous and fine. H. Samson, Esq., Bowdon, has the second place. The good old *Croton angustifolius* is very brilliant in this collection. *Azaleas* are not superior, although Messrs. Cole win the first position with large and well-flowered specimens. As a rule hardwooded greenhouse plants are not by any means so well represented as

ORNAMENTAL-FOLIAGED PLANTS AND FERNS.—In the amateurs' class of eight fine-foliaged plants Mr. Elkin, gardener to F. H. Birley, Esq., Pendleton, secures the premier place with a capital collection consisting of three *Crotons*, two large Palms, a Tree Fern, variegated *Yucca*, and a *Theophrasta*; E. Boden, Esq. (Mr. Carfield, gardener) being placed second. The same exhibitor is placed second in the class for four Palms; J. Rylands, Esq., winning first honours with remarkably fine examples of *Latania borbonica* and *rubra*, *Brahea filamentosa*, and *Thrinax elegantissima*.

Most of the plants above referred to, and many more, are arranged in the conservatory. The following, except the grand exotic Ferns from Howick House and the *Filices* from Messrs. Standish & Co., are displayed under canvas. The roof of this exhibition tent, which is considerably more than 100 yards in length, is formed of a framework of iron, and is, we learn, to be glazed, which will greatly enhance the value of the space enclosed. The ground at the ends of this tent is raised, and from the elevation, at one end at least, a commanding view is had of the Exhibition. The central walk partly overshadowed with splendid Tree Ferns from Messrs. James Dickson & Co., who secure the first prize for them, and fine Palms from Sir James Watts, Bart., Abney Hall, Cheshire (Mr. Mackellar, gardener); gorgeous groups of *Rhododendrons* sobered by graceful collections of Ferns, also banks of *Pelargoniums*, *Roses*, and *Lycopods*, produce an imposing and picturesque effect. It is a question of taste as to whether the *Rhododendrons* or Ferns in this tent bear the palm of supremacy. Perhaps, however, the last may justly be placed first, and we will therefore briefly notice the

Ferns.—These throughout the Exhibition are very superior. In the amateurs' class for nine stove and greenhouse Ferns, distinct, Mr. O. O. Wrigley wins first honours with a grand collection composed of *Cyathea dealbata*, 8 feet high, with a spread of fronds of about 15 feet; *Cibotium princeps*, head 12 feet across; C. Schiedeii; *Gleichenia flabellata*, *speluncæ*, and *rupestris* 6 feet in diameter, and G. Mendeli, a grand specimen of 5 feet across; *Davallia elegans* of the same size, and *D. polyantha* much larger and in remarkable colour. Opposite to this fine group and nearly equal in value is the notable second-prize collection of Mr. Samson. *Brainea insignis*, a striking specimen, is in robust health; and in fine contrast is the elegant *Pteris scaberula*, 4 feet in diameter. *Dicksonia fibrosa* distinct by its much-cut pinnae. *Gleichenia dichotoma* and *Cibotium Schiedeii* command attention in this excellent group. Hardy Ferns are also admirably represented, the premier prize for twelve plants being secured by Henry Crowe, Esq., Greenheys, with remarkably fine specimens of *Lastrea Filix-mas Barnesii*, *L. F.-m. cristata*, *Osmunda regalis*, *O. regalis cristata*, *O. gracile*, *Oncoclea sensibilis*, *Athyrium Filix-femina Craigii*, *A. F.-f. todeoides*, *A. F.-f. plumosum*, *Polystichum angulare plumosum*, *Lastrea dilatata lepidota*, and *Scolopendrium vulgare*. A finer collection has not been seen at any exhibition this year. J. Kershaw, Esq., Messrs. Rollisson, and other exhibitors arranged collections of great merit. The finest Filmy Ferns in the Exhibition are arranged by Messrs. J. Standish & Co. They consist of *Hymenophyllum flexuosum*, *cruentum*, and *demissum*, *Todeas* (*Leptopteris*) *pellucida* and *superba*, and *Trichomanes radicans*, all being large and in superior condition.

Lycopodiums are also extremely good, especially the first-prize collection of six pans from H. Bailey, Esq., Pendleton (Mr. Elkin, gardener). They are *Selaginella caulescens*, *Wallichii*, *laevigata*, *africana*, *microphylla*, and *Wildenovi*. The plants are 3 to 4 feet in diameter and in luxuriant health. *S. umbrosa* and *S. atroviridis* in the collection of J. Kershaw, Esq., Cheetham Hill (Mr. Gresty, gardener), are excellently grown and very noticeable. The beauty of these pans was enhanced by the remarkable pots of *Lilium auratum* exhibited by J. Fildes, Esq., and to which the *Lycopods* formed an appropriate margin. Those Lilies are 8 feet high, and

the blooms and expanding buds in each pot will certainly exceed a hundred; they are very fine indeed.

RHODODENDRONS.—Very liberal prizes were offered for these gorgeous shrubs, and collections of great merit are arranged. For a hundred plants the first prize of £25 was awarded to Messrs. Lane & Sons, Great Berkhamstead, Messrs. J. & W. Yates, Manchester, being placed second; they are second also in the class for thirty plants, Mr. A. Waterer having the premier place. In the amateurs' class for twelve plants Mr. Vickers, gardener to J. Heywood, Esq., Stretford, won the premier position with excellent plants in superior varieties. The effect of the gorgeous masses of these shrubs as seen through the vistas of Ferns is very striking. As to the varieties, we can only say that the best white in the Exhibition is *Purity*, the best blush *The Queen*, the best salmon *Mrs. Holford*, the best lilac *Everestianum*, the best rich purple *Sir T. Sebright*, the best claret *Sir J. Whitworth*, and the best crimson *Michael Waterer*.

ROSES AND PELARGONIUMS.—The absence of the giant Roses from Slough and Cheshunt was a theme of general regret. Messrs. Lane & Son secure the chief prizes in the classes for thirty and twenty-five plants respectively with compact well-grown examples, each plant having about a dozen good blooms. In the amateurs' classes the prizes were awarded to Mr. Cooper, gardener to W. J. Legh, Esq., M.P., Lyne Hall, and W. Brookbank, Esq., Didsbury, for untrained plants with good foliage and a few fine blooms. Pelargoniums are fairly represented, but the specimens, excepting perhaps the Tricolors, are not by any means equal to the plants usually staged at the London shows. Messrs. Lazenby & Sons, York, stage certainly the best but not the largest specimens in the Show class, and Mr. C. Rylance, Ormskirk, the best Fancies. The first-prize Zonals are from J. G. Silkenstadt, Esq., Didsbury (Mr. Humphreys, gardener), and the best Tricolors, and very good they are, are from E. Rogerson, Esq., Cheadle. The plants are half globes, 3 feet in diameter, fresh in foliage, and good in colour.

There is yet another huge marquee containing the collections of plants arranged for effect—*Nepenthes*, hardy plants, fruit, and cut flowers.

The £25 prize offered for a collection of plants artistically arranged in a space 25 feet long by 15 feet wide, is won by Messrs. Cauldwell & Sons, Knutsford, the remaining prizewinners being Messrs. Ker & Sons, Liverpool, and the Preston Nursery Company. The first-prize collection is composed of much the finest plants, but is not arranged with superior, if equal, taste to the others; but all the groups are far behind such free combinations as Mr. Wills produces at the London exhibitions.

Hardy plants are well represented, the lead being taken by Messrs. Rolleston & Sons with a varied and excellent collection, followed by Mr. Yates. In fine contrast to the hardy flowers are the highly meritorious collections of *Sarracenias*, *Nepenthes*, &c., from O. O. Wrigley, Esq., and Dr. Ainsworth, who are awarded the prizes in the order named. The plants are splendidly cultivated and command much attention.

Cut flowers are not extensively exhibited, but bouquets are tolerably numerous, moderate in size, and generally good. Messrs. Turner Brothers, Liverpool; Mr. Rylance, Ormskirk; and Mr. Cypher, Cheltenham, secure the prizes. Mr. Cannell exhibits cut trusses of sixty varieties of Zonal Pelargoniums, thirty single and thirty double, which no doubt surpass anything in their way hitherto seen at Manchester. They are extremely fine, and very good also are the *Mimulus* from the same exhibitor. These are very suitable plants for the moist district of Manchester, where Pansies evidently thrive well, many being well exhibited in pots. Mr. Hooper, Bath, stages a large collection of Pansies, the *Selfs* and Fancies being especially brilliant in colour; also double *Pyrethrums*. Mr. Richard Smith, Worcester, exhibits cut blooms of *Clematis* *Princess Beatrice*, colour silvery lilac, petals broad and of great substance, the flowers being of superior form and 6 inches in diameter. A first-class certificate was awarded for this splendid *Clematis*.

FRUIT.—Only four classes are provided for fruit, but the prizes are liberal. The display is not a large one, but the quality is unusually good. Mr. Miles, gardener to Lord Carington, Wycombe Abbey, won the premier prize of £10 with a collection consisting of capital and excellently ripened Pines, good Black Hamburg and Foster's Seedling Grapes, superior Read's Scarlet and Cox's Golden Gem Melons, fine Brown Turkey Figs, capital Peaches and Nectarines, and splendid Black Circassian and Elton Cherries. Mr. Bannerman, gardener to Lord Bagot, Rugeley, also stages a good collection, and is awarded the second prize. Mr. Smith, gardener to J. Rylands, Esq., secures the premier position with Black Hamburg Grapes with medium-sized compact bunches weighing about 1½ lb., the berries being large, regular, and well coloured. The remaining prizes in this class are won by Mr. Ogston, gardener to the Countess of Yarborough, Sunninghill, Berks, and Mr. Bannerman in the order named. In the class for white Grapes Mr. Bannerman is placed first with excellent examples of Buckland Sweetwater; bunches full, berries large and regular, and remarkably well finished. Mr. Gray, gardener to J. Warrington, Esq., is second, and Mr. Smith, gardener to W. Blink-

horn, Esq., St. Helens, third, both staging Muscats not quite ripe. Strawberries in pots make a rather imposing display. The foliage is closely staked so as to form a close background, in the front of which the fruit is arranged with great precision, almost every berry being honoured with a wire support. The prizes were awarded to Mr. Hinds, Otterspool, with Sir Charles Napier; Mr. Smith, gardener to J. Rylands, Esq., with President; and Mr. Henshall, gardener to W. Mather, Esq., Whalley Range, with Vicomtesse Héricart de Thury, all staging excellent examples of culture.

In the grounds large, varied, and valuable collections of Conifers and shrubs are exhibited by Messrs. Cauldwell & Sons, Messrs. Standish & Co., and Mr. Richard Smith. Mr. Waterer also exhibits fine standard Hollies, &c., in one of the tents.

On the lawn is a large display of horticultural structures, boilers implements, &c. Messrs. Richardson & Co., Darlington, exhibit large greenhouses, including one glazed with toughened glass; and Messrs. Cranston & Luck, and Holliday also exhibit greenhouses. Messrs. Leach Brothers, 27, Old Millgate, Manchester, have a large display of general garden requisites, including Crowley's mowing machines. Mowing machines are also exhibited by Messrs. Follows & Bate, who have also a large stand of garden appliances. Wagstaffe's, Harlow's, and Grimshaw's boilers are on view; and barometers and wonderfully executed artificial flowers in china are exhibited by Messrs. Davis & Co. of London.

The Exhibition is altogether both large and excellent, it is also well arranged and managed; indeed Mr. Bruce Findlay has endeavoured not only to make the Show successful but enjoyable. Judging was done under number, the class number not even being affixed on the cards, and the prizes were affixed as speedily as the nearly obsolete system permits. At all the great London shows open judging is now adopted, and the prize cards are affixed as the judges' decisions are given. No system can give greater satisfaction than this does, and no other plan is so simple and expeditious.

ROYAL HORTICULTURAL SOCIETY.

• POPULAR FLOWER SHOW, JUNE 10TH.

FOR the floral treat provided in the gardens on Whit-Monday the public who had the privilege of enjoying it at a nominal cost are greatly indebted to the Society's Assistant Secretary, Mr. S. Jennings, F.L.S., for after the idea originated of having a people's flower show on the people's holiday, he obtained private subscriptions sufficient to provide a substantial prize fund and for the purchase of plate, &c., for distribution as prizes to those preferring to have the awards in that form. The efforts of Mr. Barron, too, must be recognised, for had it not been for the assiduous labours of him and his assistants the large marquee could not have been filled so well as it was, nor the Show could not in any adequate manner have been complete and enjoyable. This will be readily understood when it is stated that besides the plants in competition and those sent by some of the principal nurserymen upwards of twenty vanloads were conveyed to the tent from the Society's gardens.

The leading object of the promoters of the display was to give some encouragement to and to afford the best examples of domestic floriculture: hence the only prizes offered were for window plants, &c., grown by the industrial classes in London, and for plants as they ought to be grown for effective home adornment—namely, the best examples of culture of those skilled cultivators, the growers of plants for Covent Garden Market, whose collections constituted the chief feature of the Exhibition.

The principal prize of £10 was won by Mr. John Reeves, Acton, with a collection of plants occupying a space of 300 feet. The plants were admirably grown and effectively arranged. They comprised *Lobelias*, *Euonymuses*, *Geraniums* of the different types, *Fuchsias*, *Hydrangeas*, *Spireas*, *Rhodanthes*, *Liliums*, *Ferns*, *Palms*, and variegated Maples. Messrs. J. & J. Hayes, Edmonton, were awarded the second prize of £7 for plants equally well cultivated but less artistically arranged. For a group of a hundred show Pelargoniums Mr. Brown, Hendon, was awarded the chief prize for splendidly cultivated plants in 5-inch pots, sturdy in habit, luxuriant in foliage, and floriferous, the heads of flowers being a foot to 18 inches in diameter. Mr. Edward Sawyer, Edmonton, had the second prize, also with admirably grown plants. For a hundred zonal Pelargoniums Messrs. Hayes staged excellent examples of *Vesuvius* a foot in diameter and 18 inches high, and received the first prize. The same exhibitors had a similar award for a hundred *Fuchsias*. To grow *Fuchsias* successfully Mr. Cannell says in his pamphlet they ought to be grown like Radishes—quickly. These had evidently received the most generous treatment, for they were extremely luxuriant and laden with fine flowers. Mr. Brown had the second prize for plants equally well grown, but only composed of two varieties, *Lady Heytesbury* and a free and fine dark sort. Mr. Reeves had the premier prize for fifty pots of Musk of the dwarf and luxuriant character for which that grower is famed. Besides the above prizes silver medals were awarded to Mr. Reeves for *Palms*, *Regal Pelargoniums*, and variegated-foliage plants; and to Mr. Sawyer for extremely fine

groups of yellow *Calceolaria Aurea floribunda* in 4-inch pots; awards were also made for various other minor exhibits.

The miscellaneous collections arranged by the nurserymen were exceedingly valuable in furnishing the large tent. Mr. Wills arranged a group as if for the inspection of princes rather than plebeians, and was awarded a gold medal. Silver medals were granted to Messrs. B. S. Williams, Rollissons, Osborns, Laing, and Dick Radclyffe & Co.; and bronze medals to Mr. Boller and Messrs. F. & A. Smith.

The contributions of the amateur artisans were not numerous, but some of them were meritorious, and the wild flowers gathered by school children were arranged with considerable taste. Silver and bronze medals and liberal money prizes were awarded in the several classes of this section of the Show, and Messrs. Sutton and Sons' prize was granted for a miniature collection of vegetables.

Now that the nature of the Exhibition is known amateur exhibitors are certain to be much more numerous another year, for we presume that an enterprise so happily originated and in all respects so laudable will become an established institution. The Show was attended by 15,558 persons on payment of 2d. each.

ROYAL BOTANIC SOCIETY.

JUNE 12TH.

A VERY excellent Exhibition was provided in the large marquee. Ornamental-foliaged plants, Ferns, Ericas, and Orchids were staged in admirable condition. The miscellaneous groups of the nurserymen, especially those of Messrs. Veitch and Bull, were extremely rich and commanded much attention. The Show was well arranged by Mr. Coomber, and was attended by a large number of visitors, including H.S.H. the Duke of Teck, the President of the Society.

ORCHIDS.—The sixteen collections staged on this occasion taken collectively were the finest we have seen in the gardens. The examples were admirably displayed on the elliptical mound and produced a gorgeous effect. In the nurserymen's class for twelve plants Mr. B. S. Williams was placed first with *Odontoglossum vexillarium* and *sceptrum*, *Oncidium sphecelatum* and *crispum*, *Dendrobium Bensoniæ*, *Epidendrum vitellinum majus*, *Aërides Schröderii*, *Cypripedium barbatum superbum*, *Cattleya Mossiæ*, very fine; *Lælia purpurata*, *Calanthe veratrifolia*, and *Vanda tricolor*. Messrs. Jackson & Sons were placed second, and Mr. Henry James, Castle Nursery, Lower Norwood, third. First honours also fell to Mr. B. S. Williams for six plants, amongst which the curious *Nanodes Medusæ* attracted attention. Messrs. Jackson & Sons were awarded the second prize.

In the amateurs' classes remarkably fine collections were staged, and Mr. Denning, gardener to Lord Lonsborough, Coombe Lane, Kingston-on-Thames, was placed first for twelve excellent examples of *Cypripedium spectabile*, *Aërides affine*, *Pescatorea cerina*, a very fine *Cattleya Warnerii*, and a grand *C. Mendellii*, a large and very fine *Odontoglossum Alexandræ*, *Aërides Lobbi*, *Lælia cinnabarina*, *Dendrobium Bensoniæ*, *Vanda Boxalli*, *Odontoglossum vexillarium*, and a very large plant of *Anguloa Clowesi*. Mr. James Douglas, gardener to F. Whitbourn, Esq., was second with an admirable collection, in which was a very fine specimen of *Cattleya Warnerii* carrying sixteen grand blooms.

STOVE AND GREENHOUSE PLANTS were well exhibited. The individual examples were not large, but they were in excellent condition. Mr. Tudgey, gardener to J. Greswold-Williams, Esq., was placed first in the open class for twelve plants with a very fine collection, comprising well bloomed plants of *Allamanda Hendersonii*, *Ixora Williamsii*, *Dracophyllum gracile*, *Dipladenia amabilis*, a large *Anthurium*, *Statiea*, *Aphelexis*, three *Ericas*, and *Azalea Distinction*. Mr. D. Donald, gardener to G. Barclay, Esq., Leyton, was second with a very good collection; and Messrs. Jackson & Son third with smaller plants. For six plants (nurserymen), Messrs. Jackson & Son were placed first; Mr. B. S. Williams, Holloway, second. In the corresponding class for amateurs Mr. Tudgey was placed first; Mr. Hinnell, gardener to F. A. Davis, Esq., Surbiton, second with exceedingly well bloomed but smaller plants, and contained amongst others one of the best plants of *Phenocoma prolifera Barnesii* we have seen for some time. Mr. Child, gardener to Mrs. Torr, Ewell, was placed third. For a group of stove and greenhouse plants arranged for effect to cover a space 12 by 24 feet in three tiers Mr. Wheeler was awarded the first prize, and Mr. Ford the second.

ERICAS were both well and numerous exhibited, and in the amateurs' class for six plants Mr. Hinnell received the first prize for *Ericas tricolor-dumosa*, *ventricosa-Bothwelliana*, *Cavendishii*, *obovata*, *ventricosa magnifica*, and *Jubana rubra*. Mr. Donald was placed second, Mr. Tudgey third, and an extra prize was awarded to Mr. Child. Messrs. Douglas, Weston, Cornhill, and Bones also exhibited in this class. In the class for nurserymen Messrs. Jackson & Son were awarded the first prize.

PELARGONIUMS.—The whole of the back side of the spacious tent was filled with these flowers, and made a most splendid display. In the classes set apart for nurserymen for Show and

Fancy varieties Mr. C. Turner, Slough, was the only exhibitor, and worthily received the first prize in both classes. A very fine collection of seedling *Pelargoniums* also came from Messrs. F. & A. Smith, Dulwich, which was awarded an extra prize. In the amateurs' class for Show varieties Mr. James, gardener to W. F. Watson, Esq., Redlees, Isleworth; Mr. W. Bones, gardener to D. M'Intosh, Esq., Havering Park, Romford; and Mr. James Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, were placed first, second, and third respectively; and in the corresponding class for Fancies Mr. D. Donald, Mr. James, and Mr. Bones were placed in the order of their names. Zonals came from Mr. J. Catlin, gardener to Mrs. Lermite, Finchley; Mr. James Weston, gardener to G. D. Martineau, Esq., Clapham Park; and Mr. Weir, who were awarded first, second, and third prizes in the order of their names. Mr. Catlin's first-prize collection comprised Thomas Adams, Remus, Maud, Col. Wright, Corsair, and a huge plant of Mrs. Turner, all profusely bloomed.

FERNS.—Mr. B. S. Williams won the chief honours in the classes set apart for nurserymen. In the amateurs' class for six large specimens Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Sussex, won the first prize with very large plants; Mr. Tudgey winning second honours, and Mr. Donald third. Extra prizes were awarded to Mr. J. Cornhill, gardener to J. S. Virtue, Esq., Oatlands Park, and Mr. J. Child. For a group of Ferns, 12 by 20 feet, Mr. Douglas staged a splendid collection and was deservedly awarded the first prize, Mr. Wheeler the second, and Mr. R. Butler, gardener to H. H. Gibbs, Esq., Regent's Park, third.

Fine-foliage plants were extensively shown, and in the amateurs' class for six large plants Mr. Rann was placed first, Mr. Child second, and Mr. Donald third, all staging good collections; and in the class for nurserymen Mr. Williams was placed first, and Messrs. Hooper & Co. second. Palms were exhibited in the open class by Mr. Rann, who was placed first, Mr. Butler second, Mr. Peed third, and extra prizes were awarded to Messrs. Osborn and Sons and Messrs. Hooper & Co. For twelve *Dracænas* Mr. Williams was placed first and Mr. Butler third. *Gloxinias*, herbaceous and old-fashioned plants, came from Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, who obtained the first prize in each class.

The following certificates were awarded—To Mr. B. S. Williams for *Areca flava*, *A. purpurea*, and *Nephrodium extensum*; to Mr. Bull for *Bowenia spectabilis serrulata*, *Adiantum tetraphyllum*, *Doodia aspera multifida*, *Aralia venusta*, *Dieffenbachia Carderi*, *Coffea Liberica*, *Macrozamia Mackenzii*, *Echinocactus cylindraceus*, *Zamia Lindenii*, *Cibotium Chamissoi*, *Kentia rupicola*, *Cœlogyne corymbosa*, *Croton Rex*, *Dracæna vivicans*; to Messrs. Veitch and Sons for *Cypripedium superciliosum*, *Begonia Davisi*, B. Duchess of Teck, B. Symmetry, *Croton Challenger*, C. Hanburyanus, *Macrozamia Mackenzii*, *Sarracenia Cheloni*, *Xeronecactus Moorei*, *Bollea celestis*, *Cattleya tricolor*, C. Mardellii, *Zygopetalum Sedeni*, *Davallia elata*, D. fijiensis; to Messrs. E. G. Henderson & Sons for *Dactylis glomerata longissima aurea* and *Saxifraga valdensis*; to Mr. Holmes, Wellington Nursery, Lichfield, for *Juniperus virginiana spica*; to Messrs. Rollisson & Sons for *Erica obovata exposita*. Extra prizes were awarded to Messrs. Veitch & Sons, Carter & Co., Bull, Williams, Parker, Low & Co., Osborn & Son, Henderson, W. Paul, Marcham, Minier, Nash, & Co., Cannell, and Soder for various exhibits in the miscellaneous classes.

The extensive display of *Rhododendrons* from Mr. Waterer and the immense collection of annuals from Messrs. James Carter and Co. are now on view in the gardens.

NOTES AND GLEANINGS.

PRESTON PROVINCIAL SHOW.—A deputation from the Local Committee, consisting of three members and the Hon. Secretary, had on Tuesday a conference with the Council of the Royal Horticultural Society at South Kensington, at which they reported progress. Arrangements are far advanced towards completion. There is every reason to expect that the Show will be a perfect success.

—As the entries for the NATIONAL ROSE SOCIETY close on Saturday week it is most desirable that everything should be put in order at once. Members are requested to take notice that tickets of admission cannot be given unless their subscriptions are paid. The Committee has made itself responsible for a large sum, and all lovers of the queen of flowers ought to help it, remembering the old Latin saying, "He gives double who gives quickly."

—MESSRS. CUTBUSH & SON afforded at the great Show of the Royal Horticultural Society sufficient evidence of the great value of *ERICA CANDIDISSIMA* as a decorative plant when flowered in a small state. Plants of this *Erica* grown and flowered in 5-inch pots were masses of purity, each plant having from four to eight spikes densely laden with white waxy flowers, and were greatly admired. This free-growing

and floriferous *Erica* is highly worthy of being grown in quantity where chaste white flowers lasting long in beauty are in demand.

— VISITORS to the Royal Horticultural Society's shows during the present year cannot fail having observed the extremely healthy and floriferous half-standard AZALEAS exhibited by Messrs. Rollisson & Sons of Tooting. The secret of the fine flowers and healthy foliage of those plants is the result of their having been planted out in the open air during the summer and potted again early in the autumn. Thus, as was suggested some time ago in these pages, the continental plan of planting out Azaleas is perfectly applicable to the south of England at least, and probably also to other districts. For the carrying-out of this practice it is necessary to prepare beds of soil composed of peat, leaf soil, and sandy loam. The soil should be pressed tolerably firmly around the roots, and the plants be watered and syringed freely. They will then, the position being somewhat sheltered yet exposed to the sun, make sturdy flowering shoots with fine leathery foliage, far surpassing that too often seen when the plants are cultivated wholly in pots. The success of the system of bedding-out Azaleas as practised at Tooting warrants trials being made of the plan in other localities.

— M. CARRIÈRE, of the Jardin des Plantes, reports on BAITS FOR INSECTS, that "beer and water" caught 850 flies and other winged creatures; "pure beer" 631; "crushed pears," "weak wine," and "pure wine" came next in the order given, and pure honey at the bottom of the list, with only seventeen victims. This would seem to disprove the literal truth of the old saying (correct as it is in its moral) that "we may catch more flies with a spoonful of honey than with a gallon of vinegar." No doubt, however, the "loud" odour of the beer, which was in a highly fermented state, had a great deal to do with attracting the insects.

— VISITORS after having inspected the rich collection of fine-foliage plants and the gorgeous Orchids cannot fail to derive pleasure and relief by inspecting the FERNERIES in Messrs. Veitch's nursery at Chelsea. The plants are admirably grown, and many of them are displayed in a natural manner on mounds and rocks. Some striking plants which arrest attention are *Marattia Cooperi*, a dwarf yet noble Fern from New Caledonia; *Nephrolepis davallioides furcans*, a large quick-growing and very elegant Fern of great value for decorative purposes. *Lomaria discolor bipinnatifida*, which Mr. Peter Veitch sent home from Australia, is very fine and is certain to become popular. *Lomaria zamioides* is a noble New Zealand species; especially bold and handsome are the barren fronds. *Thysopteris elegans*, which is said to be only found at St. Helena, is very distinct; it resembles in appearance a large *Davallia*, but produces its inflorescence after the manner of an *Osmunda*. *Dicksonia Berteroana* is a stately plant with fronds of extraordinary texture. *Didymochlæna truncatula* has striking fronds with a metallic lustre; and *Brainea insignis*, a scarce Fern, is distinct and beautiful. Ferns in baskets are most elegant, and the thousands of *Filices* impart variety and elegance to this fine collection.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THE white Water Lily of English lakes and ponds until recently had never been known to paint its blossoms with the rose tints of its tropical relatives. This innovation of colour has been found only in one particular lake in Sweden, doubtless a great surprise and pleasure to its discoverer. The first plants to leave the country of its origin were doubtless those sent to Kew, and now the first flower to open in this country is, we believe, the one we have just seen. It is of beautiful colour, though less deep, no doubt, than it will be when the unusually cloudy weather for this season has given way to a brighter sky. It has been thought that its colour is due to some principle in the water of its native lake, but however this may be, it is probably permanent. There is perhaps nothing in flower of more general interest than this, and fortunately there are many buds to insure a succession of bloom. We are glad to hear that a continental nurseryman has succeeded in raising a stock from seeds. From this water plant we are led to another, quite new and extremely pretty. In the Cape house in a bellglass is *Aponogeton spathaceum* from the Cape. It is quite unlike the familiar *A. distachyon*; the leaves shoot above the water nearly erect, almost like a Rush, and present no distinction between blade and petiole.

The inflorescence is raised to nearly the height of the leaves; it is quite a miniature of the species we have just mentioned, and has a delicate touch of blush pink, but no perfume.

Those who regard with interest the favourites of nearly a generation ago will find much to examine in the collection of Cape Pelargoniums, of which about three dozen species are in flower, as well as several hybrids, some of the former with deep colours and shades never attained by the fancy varieties. Many are curious and all with a feature of some kind, either in perfume, foliage, strange habit, or floral beauty. *Whalenbergia tuberosa* from Juan Fernandez, with perennial rootstock and white flowers, is quite unlike our previous idea of the genus. It has erect stems with narrow leaves, and is in all a pretty plant.

Elisena longipetala is finely in flower, and is extremely rare as well as beautiful. The flowers are pure white, the perianth segments are tortuous, almost winding about, and the margin is wavy. It comes from Lima, and is not unlike *Ismene*, to which it is allied. The beautiful flowers of the new *Iris speculatrix* from Hong Kong are known to few. The sepals are blue-lilac, with white central portion. Its leaves are narrow and stiffly erect.

Many Irids are flowering in the Herbaceous ground, and the most effective of all at the present time is *Xiphion lusitanicum*. Its self golden-yellow flowers are more than 4 inches across. The choice kinds include *I. Douglasii*, as one of the newest; *I. tectorum*; *I. versicolor*, one of the most richly coloured; *I. lævigata*; *I. pallida*, with immense pale blue flowers, and *I. cashmeriana*.

The choicest herbaceous plant in flower, besides possessing a large share of beauty, is *Chrysanthemum Catananche*. It is quite the gem of the genus. The leaves are tufted, cut into silky linear segments, from among which the scapes rise to a height of 6 or 8 inches, bearing golden-rayed flower heads about $1\frac{1}{2}$ inch across. It is one of the most beautiful plants of the Greater Atlas, where it was discovered by Sir Joseph Hooker, Messrs. Maw and Ball, in 1871.

Castilleja indivisa, we believe, is one of the finest plants of the North American flora. It has recently been introduced by Mr. Thompson of Ipswich, and a plant is now in flower on the rockwork. The great attraction of this plant is the large bracts, green below and fiery scarlet above; the flowers, though of the same colour, are small. The genus is a beautiful one, but owing to the majority of the perennial kinds being parasitic not many are amenable to cultivation. *Anemone obtusiloba* is a rare and pretty species, to which more than once at this time of the year we have drawn attention. It is again in bloom, the white flowers clustered together above a leafy involucre. *Tovaria oleracea*, which lately has been blooming near the *Fremonia californica* on the herbaceous ground wall (itself soon to be a sheet of yellow blossoms), is an interesting and beautiful plant. It was not long since introduced to Kew from Temperate Sikkim, and last year flowered for the first time, and was figured in the "Botanical Magazine." It is the most striking species of the genus; the stems sometimes grow to a height of 6 or 8 feet, and bear panicles of white flowers often a foot across. The young flower heads sheathed in the tender leaves form an excellent vegetable.

In the Conservatory is a large specimen of *Chrysanthemum Broussoneti*, rarely seen in this country, but in Paris, where Daisy-like flowers appear to be popular, it is grown with *C. frutescens* and often used outside the restaurants, and in winter stored away in cellars with Myrtles and other plants. The flowers are larger than those of *C. frutescens*, and it also has greater breadth of foliage. The new *Boronia elatior* is finely in flower, and in colour is deeper than any other carmine-coloured species.

In the Orchid collection a single *Dendrobium* is worth special mention. Its flowers are white, sepals and petals tipped with pink, and the labellum creamy with pink markings; the special feature, however, is the delicious and strong perfume of Violets.

FRUIT PROSPECTS.

IN NORTH WILTS.

I AM afraid it is impossible to speak as favourably concerning what I may term the general fruit harvest now as I could have done a month since. The climate here is nearly as good for fruit as the neighbourhood of Bath. The soil I have to do with is excellent. I have examined other gardens than my own and inquired about more, and my own appears to be a fair sample. Hence I will simply give my fruit prospects in

a usual-sized rectory garden situated on a hill with a pleasant slope to south and west, protected by the church and shrubbery from the east wind, and with a hill at back securing me from northern gales. Hence the situation is favourable, being only open to the sunny south and showery west. A month since all appeared promising, now much is changed to the reverse. The first injury that the blossoms received was, I think, in that storm in which the "Eurydice" was lost, Sunday, March 24th. The weather before had been genial and the Pear blossom exquisite, but snow fell on that day, not sufficient to be a cover but enough to remain as a sprinkling. Upon that damp sprinkling came a frost, and partly true was the line in Henry VI.—

"Thus were my blossoms blasted in the bud."

This was true in respect to many of my Pears. However, they bloomed fairly, in some cases abundantly, but I have not a full crop on any. The best, probably a third of what ought to have been, is on the following trees:—Jargonelle, Summer Doyenné, Beurré Giffard, and Madame Treve; a sprinkling on Bergamotte Esperen, a very few on Soldat d'Esperen, Beurré Diel, and Beurré d'Amanlis. Those that have wholly failed are Williams' Bon Chrétien and Seckle, which for three seasons has not had a single blossom; Beurré Hardy ditto; Napoleon few blossoms but no fruit; and Winter Nelis, Louise Bonne of Jersey, and Josephine de Malines also no blossom, but they were only planted last November.

Wall Plums are plentiful, I should say a magnificent crop, but heavily blighted in some gardens. Standards and pyramids very poor. Damsons a light crop and scarcely a single Bullace. This has happened two years in succession, which is curious considering that as a rule Bullaces are certain croppers. I may notice that we have had very heavy storms, much rain, and winds, which have so knocked about the branches of the standard Apples, Damson trees, &c., against each other that the leaves are browned and blackened and now very thin as you look up through the trees.

I come now to Apples. This fruit, we were assured, would be very plentiful, and I thought so too, but it will not be the case I much fear. The trees, all of them, blossomed well. The fruit set apparently well; but whether from wind, or blight, or weakness arising from the frost, a general dropping of the fruit has taken place, and the crop is now scarcely half what I expected. Some trees now have not one Apple on them. The grand exception is, as always, the Hawthornden, which on my soil does not canker to any amount. I have one tree in full bearing forty years old, another above twenty. These never fail, and the fruit while it keeps is not excelled by any. It will not be wise to do away with this Apple, and I regret that it has been written against; where the soil suits it is the best fruit of its season. Lewis's Incomparable has a good crop, and another late cooking Apple, a local variety. I have also some dozens of pyramids, which I had from Worcester, which much please me, and come, I need scarcely remark, always true to name, for Mr. Smith is always to be relied on. There is a small crop still left on each pyramid Apple tree: those bearing best are Lord Suffield, Duchess of Oldenburg, Margaret, Cox's Orange Pippin, Summer Golden Pippin, New Hawthornden, Golden Pippin, Sturmer Pippin, Ecklinville Seedling, Cellini, and Tower of Glammis. Leaf blight, that strangely varying thing, has struck here one and there another, going up the middle of tree perhaps, but leaving the outer branches untouched. I find the pyramid plan much the most interesting in both Apples and Pears; not that I intend to sacrifice fruit to form or to the smallness of the tree, but in a pyramid you have your tree near you to watch it in all changes and it is less injured by winds.

Gooseberries are a short crop with everyone, while on the other hand the supply of Currants appeared to promise to be inexhaustible. But lo! the bunches are half bunches. They, though of course still quite green, resemble what later on would have been regarded as bunches half stripped by the birds.

I had written thus far when my copy of the Journal of June 6th came to hand, and I have read the remarks of "THE HEREFORDSHIRE INCUMBENT" and the Kentish cultivator. The latter's remark as to the "mysterious disappearance of fruit" exactly tallies with my experience. This morning, June 7th, I have just been round my garden, and find still fewer Currants, Gooseberries, Apples, and Pears. My old man's observation during the past fortnight has been, "Wait, sir, till they grow bigger and show themselves;" but they have grown bigger, these few left, and the many have gone, and so don't show themselves. Why or for what cause

the fruit has disappeared I cannot tell, but it is only from the standards and trees in the open, and not from wall trees. This looks like the effect of frost which injured, but its effect was slow. Slow poison is sometimes sure poison. Judging them from present appearances this year will, I greatly fear, be like the last a bad fruit year, the exception probably being Strawberries.—WILTSHIRE RECTOR.

P.S.—It would be both useful and interesting for fruit-growers to notice and record their experiences with their trees, particularly what Pears and Apples not only blossom but mature their fruit in such seasons as the present.—W. R.

THE prospect of a good fruit crop here this season has been sadly dimmed in the last fortnight. The severe weather at the beginning of April cut off some of the Apricot blossom, but enough set afterwards for a crop, but nearly all that has fallen off since. Gooseberries are scarce. Red Currants not over-abundant; Black pretty good. Plums against walls a very good crop. Strawberries promised a wonderful crop at one time, and some of the earliest are set fairly, but I am very much in doubt about some of the late blooms, and think a great many of them will, what is called, "go blind." Pears will be rather scarce; there was not much bloom on the trees, and the Apples will not be the abundant crop at one time anticipated. Several of my trees had the blossom buds cut off by the bad weather early in April, particularly the bush trees. In one place, perhaps, all was cut off, while the next tree was uninjured; I attributed the injury to the snow resting on the branches. Those trees which escaped injury then blossomed wonderfully well, and a good crop was set, but, alas! from some trees all, and upon others nearly all, has dropped off since. What was the reason of it? The answer is not far to seek. It was not frost, the grass was whitened one or two nights, but there was not enough frost to do any injury; neither was it blight, nor too free growth, for I have some trees which have made but little growth and the result is the same. The cause of the failure was the continued rains, the sodden state of the soil, and the absence of sun, so that I agree with "THE HEREFORDSHIRE INCUMBENT" as to the cause. I enclose a copy of the rainfall from the 1st of May to the present time, by which you will see there were only three or four days without rain.

Vegetable crops are looking well, Potatoes never better, having no frost to interfere with them; but everything now wants sun or the consequences will be serious.—AMATEUR, Cirencester.

ROSE PRUNING—GIVING NOTICE.

"WINTER shows," says the proverb, "what summer conceals." I incline to think that summer time shows a good deal also, especially as to the effects of severe pruning. I incline to think that we prune too severely. I observe that Mr. Camm is now advocating letting Tea Roses almost entirely alone. A bush of mine that escaped the knife—Reine du Portugal—under a south wall, certainly is at the present a strong supporter of his theory. Out of fifty nearly that have been pruned this which escaped is far the strongest. Also, I observe in some cottage gardens where I have budded Briars for the occupants, and where the Roses are allowed to grow exactly after their own will and pleasure, now and then I come across some magnificent bushes, three to four times the size of any that my carefully cut-back Briar stocks attain to, and the great strength of the trees is promising blooms in proportion. Certainly for the future I shall only show the knife to *Maréchal Niel*; my plants of it this summer are more like "Die Johns." I pruned hard hoping for blooms a month later than "Glories," and there are not half a dozen bloom buds amongst twenty of them. Only a few weak shoots have been put out, and there is no new wood of any promise. "Rome," said the intelligent American, "is a fine city, but its public buildings are rather out of order." *Maréchal Niel* under glass is a matchless Rose, and against a house where it has its own way may be splendid, but it is not by any means a Rose to be grown under difficulties, and it is certainly most uncertain grown in the open.

I return to my first suggestion—whether the results of severe pruning shown as summer advances do not sometimes contrast unfavourably with plants which have been let to grow freely—whether in many cases considerably less shortening back might not be advisable?

The managers of Rose shows, and very reasonably, for the most part require a week's notice of exhibition, and to know the classes. It is perhaps useful to call attention to this at the

present time. Terrible havoc amongst possibilities was made at the last National show by neglect of this precaution. The tender-hearted but determined Secretaries rejected most resolutely all too-late arrivals. Who knows the victors who may not have been thus extinguished? Some rising Baker or Jowitt perhaps left the Cranston cup that day unchallenged.

I observe the Royal Horticultural name June 15th as the last day of entry, so also the Alexandra Palace. Nothing will avail for the National after June 22nd. Horsham has fixed June 25th for the latest entry, and for the Reigate Show on July 6th; the entry closes, unless I am mistaken, June 23rd.—A. C.

CHOICE GARDEN ORCHIDS.

ÆRIDES, *Lour.*

ETYM.—*Ær*, the air, in allusion to their epiphytal character.

An extensive genus, containing many large showy-flowered species, which even when not in flower are for the most part extremely ornamental. The leaves are distichous (two-ranked), coriaceous or somewhat fleshy in texture, unequally truncate at the ends, but in some few species the leaves are terete. Flowers produced upon long racemes, which are often branched. Sepals and petals spreading; the lateral ones oblique at the base and joined to the prolonged foot of the column, spurred and three-lobed. Column recumbent on the ovary, short and destitute of wings. Anther two-celled. Pollen masses two. Caudicle narrow, membranous. Gland peltate, roundish.

CULT.—The plants comprising this genus may be grown into very handsome specimens providing heat and moisture are duly supplied them. The majority thrive best and retain their lower leaves longest when grown in pots or baskets surrounded with living sphagnum moss. We say living moss, because it then is sure to be sweet and fresh, for the roots of *Ærides* soon decay if allowed to remain in anything sour or decaying. During the summer season they enjoy gentle syringing, but care should be taken that the water is not allowed to accumulate in the sheathing bases of the leaves. The small-growing kinds may be successfully treated upon blocks; but in whatever position they may be grown their leaves must upon no account be allowed to shrivel for want of water. The green and yellow fly should be washed off with tepid water. White scale when it makes its appearance may be cleared away with either soft soap or Abyssinian mixture; and the red thrips, which so much disfigure the members of this family, must be treated with some dry tobacco powder. This should be dusted into the axils of the leaves and allowed to remain there in a dry state for a few days. Some fumigate to destroy these pests: we, however, dislike the system, believing it is a fertile source of the decay of the bottom leaves, which renders these plants very unsightly. All are natives of Asia. Temperature—Summer, 75° to 85° day, 65° to 75° night; winter, 65° to 70° day, 60° to 65° night.

A. affine, Lindl. (Wall. Cat.; Sert. Orchid. t. 15). Syn., *A. trigonum*, Kl.; *A. roseum*, Lodd.; *A. multiflorum*, Hort.—This is an elegant and very ornamental plant. Leaves about a foot long, truncate at the ends, sometimes toothed, light green. Racemes somewhat erect, sometimes branching, many-flowered. Flowers pink and white, more or less spotted with rose. Sepals and petals about equal, rounded at the tips. Lip rhomboid acute, slightly three-lobed, twice as long as the ovary. Spur short and conical. May and June. Sylhet and Nepaul. 1837.

A. affine, Lindl.; var. *superbum*, Hort.—A splendid form of the preceding, having a more robust habit of growth. Raceme dense and much branched. Flowers varying from rosy and white to deep rose, and profusely spotted with rosy purple. May and June. Assam. 1837.

A. japonicum, Rehb. fil. (Bot. Mag. t. 5798).—This species is of somewhat recent introduction, and nowhere has it yet been grown to any size. Leaves 3 inches or more in length, about an inch wide, linear oblong, recurved, keeled below, unequally two-lobed at the apex, dark green on the upper side, paler below. Raceme pendulous, sometimes branched, lax-flowered. Sepals and petals oblong obtuse, waxy white, slightly tinged with green and more or less transversely banded with reddish brown. Lip obovate spatulate, slightly notched and swollen on the under side; lateral lobes oblong, white spotted with violet, with a raised band of the latter colour along the centre. Spur short, funnel-shaped. Flowers delicately fragrant. May and June. Southern Japan.

A. Lindleyanum, Wight. (Ic. Ind. Or. O., t. 1677). Syn.,

Saccolabium speciosum, Wight? *Ærides crispum* Lindleyanum, Hort.—This is a plant of robust and noble habit, resembling somewhat a gigantic form of *A. crispum*. Leaves coriaceous, oblique and obtuse, bilobed at the apex, some 6 inches long, very deep green on the upper side, slightly paler below. Racemes much-branched and many-flowered. Sepals and petals nearly equal, the lateral ones being slightly the largest and obovate; colour rosy lilac margined with white. Lip three-lobed, ovate acute; lateral lobes much smaller than the middle; the latter large and spreading, swollen above and toothed at the margins, and ornamented at the base with a plaited fleshy lobe, deep rich rose narrowly edged with white. Spur short, incurved. May and June. Madras.

A. mitratum, Rehb. fil. (Bot. Mag. t. 5728).—A low-growing species, having long, slender, cylindrical leaves, which are upwards of 2 feet long, channelled above, tapering upwards to a fine point, and intense deep green in colour. Racemes erect, 6 to 10 inches high, dense, many-flowered. Flowers upwards of half an inch in diameter. Sepals and petals sub-equal, oblong, obtuse, and pure white. Lip larger than the sepals, not quite flat, having a small projection on each side at the base. Spur short and thick, bent backwards, dilated at the base. Spring and summer. Moulmein.

A. quinquevulnerum, Lindl. (Sert. Orch., t. 30).—The leaves of this splendid species are ligulate, obliquely notched at the apex, with a little point in the middle, tightly clasping the stem at the base, about 12 inches in length and light shining green in colour. Racemes pendulous, many-flowered, longer than the leaves. Flowers large, dense, and slightly fragrant. Sepals and petals rounded, nearly equal, white dotted with crimson, and stained with purple at the tips. Lip cucullate, three-lobed; lateral lobes erect; middle oblong, incurved, denticulate and stained with crimson-purple. Spur conical, incurved, green. Summer and early autumn. Philippine Islands. 1838.

A. quinquevulnerum, Lindl.; var. *Farmeri*, Hort. Syn., *A. quinquevulnerum* var. *album*, Hort.—This very rare variety is stiffer in habit than the species, and the leaves are of a much deeper green, but they have the same habit of tightly clasping the stem at the base. Raceme pendulous, longer than the leaves, dense. Flowers fragrant and pure white. July and August. Philippine Islands. 1850.

A. Reichenbachianum, Lindl. (Xenia Orch., t. 104).—In general appearance this plant resembles *A. quinquevulnerum*. Racemes pendulous, many-flowered, longer than the leaves. Flowers white, with large amethystine blotches at apex of sepals and petals, dotted with the same colour towards the base; upper sepal cuneate, roundly ovate, acute; lateral ones bluntly triangular, their edges revolute. Petals narrower, falcate, slightly toothed. Lip three-lobed; lateral ones axe-shaped, erect, serrulate on the front edges and rich golden yellow; middle lobe ligulate, serrulate above, bearing two teeth at the apex. Spur conical, incurved, green. July and August. Borneo.

A. roseum, Lindl. (Bot. Mag., t. 4049). Syn., *A. affine*, Hook. (non Wall.) in Bot. Mag.—A robust-growing plant, which appears to dislike moisture to collect about its roots, therefore it should be kept drier than the other species. Leaves coriaceous, channelled, recurved, with a blunt two-lobed apex. Racemes dense, pendulous, many-flowered, and 12 to 15 inches in length. Sepals acute, narrow at the base. Petals longer and not so wide as the sepals, pale rose. Lip flat, rhomboid, entire, and tapering to a point, bright rose, spotted with a darker shade of the same colour. Spur short, incurved. Ovary triangular, as long as the lip. June and July. Assam. 1840.

A. roseum, Lindl.; var. *superbum*, Hort.—A much superior plant than the normal form. It is freer-growing and more robust in habit. The racemes are longer and very dense. The flowers are larger in all their parts, and deep rich rose, profusely spotted. June and July. Assam. 1843.

A. suavisimum, Lindl. (Pxt. Fl. Gard., ii., t. 66).—A handsome, distinct, free-growing species. Leaves somewhat flaccid, about 10 inches long, light green, freckled with brownish dots. Raceme longer than the leaves, many-flowered, dense. Flowers deliciously fragrant. Sepals and petals ovate obtuse, spreading, white tipped with lilac. Lip horned, turned upwards and pressed close to the column, three-lobed; lateral lobes oblong, slightly toothed; middle lobe dwarf, linear, bifid, pale lemon colour, point of spur rosy red. June and July. Malacca. 1848.

A. suavisimum, Lindl.; var. *aurantiacum*, Hort.—A superb

variety, differing mostly in the colour of the middle lobe of the labellum, which is rich orange yellow, rendering it very distinct. The entire flower is much larger than in the species. June and July. Borneo. 1866.

A. suavisimum, Lindl.; var. *flavidum*, Lindl.—Although distinct from the other forms, this, it must be acknowledged, is inferior in beauty. Sepals and petals white tipped with pale pink. Lip horned. Lateral lobes rounded, entire, very pale yellow; middle lobe bifid and same colour. July and August. Malacca. 1848.

A. Thibautianum, Rchb. fil. (fig. 68). (Bot. Mag., t. 5681). Syn., *Saccolabium Huttoni*, Hook. fil.; *Aërides Huttoni*, Hort. Veitch.—In general appearance this plant resembles *A. quinquevulnerum*, and the leaves have the same habit of tightly clasping the stem. Leaves 6 to 8 inches long, unequally two-lobed at the apex, and deep green. Raceme pendulous, slender, many-flowered, upwards of a foot long. Flowers large and fragrant, and soft deep amethyst in colour. Sepals broadly oblong. Petals cuneate, obovate, spreading. Lip three-lobed. Lateral lobes falcate; middle lobe strap-shaped and acute.

FIG. 68.—*AERIDES THIBAUTIANUM*, after "Bot. Mag.," t. 5681.

Spur conical, obtuse. August and September. Java and the Polynesian Islands. 1866.

A. vandarum, Rchb. fil. (Bot. Mag., t. 4982). Syn., *A. cylindricum*, Hook. (B. M., t. 4983).—This plant, it would appear, is erroneously referred to *A. cylindricum* in the fig. above quoted. Leaves round, channelled above, 4 to 6 inches long, dark green. Racemes short, one to two-flowered. Flowers large, white. Sepals obovate and strap-shaped with waved edges. Petals similar in shape, reflexed, and, like the sepals, waved at the edges. Lip three-lobed. Lateral sepals broad, ovate, acute; middle retuse and crested. Spur short, conical. Spring and summer. East Indies. 1856.

A. virens, Lindl. (Bot. Reg., 1844, t. 41).—Leaves broad, oblique, and terminate in an obtuse point, with a depression

in the centre, bright shining green in colour. Raceme drooping, many-flowered. Flowers deliciously fragrant. Sepals and petals obovate, obtuse, delicate French white tipped with a deep rosy purple blotch. Lip large. Lateral lobes slightly toothed at the points and speckled with crimson; middle lobe bearing an inflated sanguine serrated tongue. Spur ascending, tapering to a fine point. June and July. Java. 1841.

A. virens, Lindl., var. *album*, Hort.—This variety is undistinguishable in its growth from the normal form. Racemes pendulous, dense. Sepals and petals white, faintly tipped with lilac. Lip white, sparingly dotted with pale lilac. June and July. Java.

A. virens, Lindl., var. *quinquevulnerum*, Hook.—This variety is more robust in growth than the species. Racemes dense,

pendulous, branched, 12 to 18 inches long. Flowers very fragrant. Sepals and petals spatulate, pure white, with a heavy rosy purple spot on the tip of each; lateral sepals obtuse, double the size of the petals. Lip pressed close to the column. Lateral lobes white, streaked and dotted inside with purple, which is faintly visible on the outer surface; middle lobe rich rosy purple. Spur tipped with green. April and May. Java. 1865.

DISAPPEARANCE OF FRUIT.

AT the beginning of last month Apple, Pear, Plum, and Cherry trees were completely covered with blossom, which appeared to set well and progress favourably for some time, but I assure you that a thorough transformation has taken place, but through what cause I cannot say. The weather has certainly been very cold and wet, but now on most of the Pear, Plum, and Apple trees it would be difficult to find a single fruit, and the Cherries, Gooseberries, and Currants are all similarly affected.—A. W. BIRD, *Florist, Sheffield*.

BATH AND WEST OF ENGLAND SOCIETY.

OXFORD, JUNE 10TH.

AT the exhibitions of a Society the aim of which is the encouragement of agriculture, arts, manufactures, and commerce, it is reasonable to suppose that horticulture should occupy an important position. Such a position is undoubtedly accorded it, and in a manner worthy of the art which it illustrates—most worthy so far as it goes, so much so that we cannot but regret not seeing every branch of horticulture represented under such able supervision as is here brought to bear upon the work by the Hon. and Rev. J. T. Boscawen.

The Show is a peculiar one, consisting entirely of plants and cut flowers, not brought into competition for prizes, but so arranged as to produce tasteful effects. To do this in the best way the most suitable plants are chosen, so that those belonging to a single exhibitor are not grouped together, but are dispersed among others, and present to the eye in the most advantageous manner. They are exhibited in a tent 135 feet long by 50 wide, thoroughly ventilated, and admirably suited for the purpose. The interior arrangements are simple and good. Connected with the end by which the public gain admittance is a long central stage arranged in three tiers with a high central elevation. It runs along towards the upper end of the tent not in straight but in curved lines, thus presenting none of the too common aspect of offensive formality present in most stages. The stage is covered, not with green baize, but with soft felting of a light brown tint in harmony with the colour of the roof and ends of the tent, and forming a capital foil to the various shades of green in the foliage and to the bright colours of the flowers, which appear all the brighter from such a background. The plants are arranged in exquisite taste. All along the high central tier are lofty Palms, Bamboos, and Cordylines, the crown and glory of the stage being a magnificent example of *Sabal umbraculifera* from G. May, Esq., standing aloft upon the highest place and spreading its huge fronds gracefully outwards and downwards. At one end is a lofty *Theophrasta imperialis*, at the other an *Alsophila australis* from Col. Loyd Lindsay, with *Lantanas*, a very fine *Cycas revoluta*, and other fine plants. On the lower stage plants equally fine but not so lofty impart beauty to each other and grace to the whole. Some of them are so fine as to merit special attention. A group consisting of *Maranta Veitchii*, a *Clerodendron Balfourianum* from G. May, Esq. (gardener, Mr. Parham); a lovely *Dipladenia amabilis* from the Earl of Jersey, whose gardener, Mr. H. Hain, had many other good plants here; an *Adiantum gracillimum* grown by Mr. Parham, and a *Clerodendron fallax* from Mr. Hain with two grand spikes of its showy scarlet flowers, were very beautiful, and the charmed eye wandered on to the lovely tints of *Bougainvillea glabra* hard by a grand *Stephanotis*, a charming pair of plants, both from the garden of G. May, Esq. *Statice profusa* from the Earl of Jersey's garden at Middleton Park is a huge plant nearly 2 yards in diameter, thick set with flower clusters and in fine health, as too was an equally large and very fine *Lantana Le Grenadier*, with a profusion of deep orange-coloured blossom. Of other really fine and finished specimens I may take Mr. Parham's *Rhynchospermum jasmimoides*, a *Cocos Weddelliana* from Col. Loyd Lindsay, with a very large *Calanthe zebrina* from the same gentleman's garden; a *Caladium Belleyneii*, a *Vinca alba* 8 to 4 feet in diameter in good bloom, an *Erica Cavendishiana*, and a *Pandanus humilis*. Numerous smaller plants are mingled in tasteful groups, bright colour being imparted by zonal *Geraniums* and Cape *Pelargoniums*, softer and more lovely tints being found in the numerous *Orchids* contributed by Sir William Marriott, many of the pendant spikes nestling charmingly among clusters of Maiden-hair Ferns.

Along one side of the tent a row of large standard Bays is found

alternating with irregular triangular clumps of blue and white Pansies, and onwards towards the upper end a pleasant break is introduced in the form of a collection of hardy Ferns in pots. Very beautiful in form are the following—*Athyrium Filix-femina* var. *todeoides*, having light elegant frondage of a pale green hue; *Scolopendrium vulgare* var. *ramo-eristatum*, *Polystichum angulare* var. *angustifolium*, *Athyrium Filix-femina* var. *plumosum* very elegant, *Osmunda regalis cristata*, *Polystichum angulare plumosum*, massive in effect and of much beauty, the fronds being quite plume-like.

Of cut flowers there is a collection of rare Orchids, another of Cacti, also of Ranunculi, Roses, and an interesting collection of British wild flowers by Rev. W. Tuckwell. The Exhibition was not, however, complete when these notes were taken, more Orchids being promised and more cut Roses.

A bold group of plants at the upper end of the tent demands notice, consisting of an immense Screw Pine, planted upon a raised mound having some fine specimens of Ferns around its base, and near them an interesting exhibition from J. Dorrien Smith, Esq., Tresco Abbey, Isles of Scilly, consisting of flower spikes cut from plants growing in the open air of *Dracena indivisa*, which there is from 12 to 16 feet in height, the flower spike being thick and bushy; *Cordylina erythrorachis*, of more dwarf and spreading growth with the flower spikes long and slender; also flower spikes of a seedling raised there which is considered a cross between the other two plants, partaking of the tall habit of *D. indivisa* and foliage of *C. erythrorachis*. It is a very interesting variety, more beautiful than either of its parents. A flower spike of *Chamerops excelsa* was also sent.

A charming collection of cut Irises from the Oxford Botanical Gardens forms an attractive addition to the Show. The novel forms and varied colours of the flowers evidently attract and please, very little being known generally of many of them. In colour they range through many shades of pink, yellow, and blue, white and black too being not altogether unrepresented; one named Queen of Gypsies having under petals of a rich velvety black, and *Alba purpurea* having much white upon its petals. A pretty group of French Pansies in pots must also be noticed; and a brace of Daniell's Duke of Edinburgh Cucumbers shown by Mr. Hookham of Summertown are so large and symmetrical, both being apparently upwards of 30 inches long, as to merit a word of praise.

In other parts of the Exhibition yard implement makers and seedsmen are in great force. Messrs. Sutton & Sons of Reading have a large stand, remarkable not only for its tasteful arrangement for a collection of fifty sorts of old Potatoes, the tubers being in wonderfully good preservation. Messrs. Carter also exhibit seeds and roots, and Messrs. E. Webb & Sons of Wordsley, Stourbridge, have an attractive stand. Mr. J. Matthews of Weston-super-Mare has a stand of pottery, comprising among other things a useful form of Orchid pan, shallow and perforated with holes. Of glass structures there are several examples; one by Mr. Parham of Bath and Oxford Street, London, being worthy of especial note for the patent light hollow iron rafters on which the sides of the glass rest and serve to carry off all drip. Mr. Perry of Banbury has a span-roofed house presenting an excellent combination of strength, lightness, and ample ventilation with convenient staging. Tools and garden implements of all sorts in improved and novel forms are also represented.

Our leading nurserymen cannot be aware of the magnitude of the Show or of its comprehensive nature, or they would see that it would be worth while to follow the lead of the seedsmen. The Exhibition opened on Monday and closes on Saturday.

SOUTH ESSEX HORTICULTURAL SOCIETY.

ESSEX can boast of several flourishing horticultural societies which hold really fine shows. That held by the above Society in the grounds of J. G. Barclay, Esq., at Knotts Green, Leyton, is generally considered one of the best, and the one held on June 6th was no exception to the rule. The extensive and well-kept gardens of Mr. Barclay also proved a source of attraction to many visitors. This gentleman's able gardener (Mr. Donald) not only exhibited largely and successfully, but at the same time did so without any apparent detracting from the appearance of a very fine conservatory. This structure is divided into compartments for stove and greenhouse plants, and there are also two excellent examples of grotto work, which were delightfully cool with the water constantly trickling over the rocks, &c. Mr. Donald deserves great credit for the general appearance of the conservatory, and also for one of the grottos that he constructed.

In nearly all the classes in the schedule there was strong competition, and in several instances extra prizes were awarded by the Judges (Messrs. Ward, J. Fraser, Barley, and Sweet), so good and even were the exhibits. In the class for eight stove or greenhouse plants Mr. Donald, gardener to J. G. Barclay, Esq., was first with large but rather overtrained specimens of *Erica Cassoniana* and *ferruginea major*, *Aphelaxis macrantha purpurea*, *Franciscea confertifolia*, *Clerodendron Balfourianum*, *Hedera tulipifera*, *Statice profusa*, and *Dracophyllum gracile*. Mr. Bones,

gardener to D. McIntosh, Esq., Havering Park, Romford, was a good second. In the corresponding class for four varieties Mr. Bradley, gardener to O. E. Cope, Esq., and Mr. Lane, gardener to General Fytche, Pyrgo Park, Romford, were placed equal first. Mr. Bradley staged a good *Anthurium Scherzerianum*.

Orchids were staged in considerable numbers; none were large, but the first prizes were awarded to very creditably grown plants. For six Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, and Mr. Walton, gardener to A. Borwick, Esq., were placed equal first. For three plants Mr. Lane was first, and Mr. Monk, gardener to — Fowler, Esq., second. Mr. Donald was first with four *Ericas*, and Mr. Bones second. There was excellent competition in the classes for Tree, Exotic, and British Ferns. Mr. Donald was first for six Exotic, Mr. Douglas for four ditto, and Mr. Walton for six British Ferns. Mr. Donald staged a good *Davallia Mooreana*. Mr. Douglas was first for six *Lycopodiums* and also for six fine-foliage plants, staging excellent specimens in 15-inch pots of *Croton Weismannii*, *Cocos Weddelliana*, *Cycas revoluta*, *Pandanus Veitchii*, *Dasyllirion gracile*, and *Kentia canterburyana*. Mr. Donald was a good second in this class. Mr. Lane was first for single specimen foliage plant with a very attractive and well-grown plant of *Lomatia heterophylla*. This and other varieties of *Lomatia* ought to be more grown, being very attractive either in a young state as table plants or as shown by Mr. Lane. In the corresponding class for plants in flower Mr. Donald was first and Mr. Douglas second. Both staged very fine specimens of *Clerodendron Balfourianum*, the Judges apparently giving the preference to the most precisely trained plant.

Pelargoniums were well shown, many specimens being particularly fine. Mr. Bones was first for six large-flowering, staging fine examples of *Chieftain*, *Maid of Honour*, *Emperor*, *Ariel*, *Rob Roy*, and *Example*. Mr. Monk, gardener to F. Head, Esq., was first in the corresponding class for four plants. Mr. Donald was first for six *fancies* with really fine specimens of *Ellen Beck*, *Mrs. A. Wigan*, *Roi des Fantaisies*, *Lucy*, *Marmion*, and *Mrs. Mendell*. A good feature in this group was the comparatively small number of sticks used for training. Mr. Bones was second. There were also classes for *Fuchsias*, *Coleuses*, *Gloxinias*, table plants, &c. The first-prize *Calceolarias* staged by Mr. Foster, gardener to R. Johnson, Esq., were very fine.

There was good competition in the various classes for cut flowers, but the *Roses* were scarcely up to the mark. Dinner-table decorations, vases, bouquets, &c., were scarcely so good as usual. Miss Spicer won the silver cup for a group of three vases. The framers of the schedule erred in deciding the minimum height of the vases to be 18 inches, as most of the exhibitors used very tall vases, the only exception being the first-prize group. It is a mistake to employ tall plants or vases on the dining table.

Fruit was shown in small quantities, but the quality to a certain extent compensated for the scarcity. Mr. Bones was first and Mr. Douglas second in the class for black *Grapes*, both staging good examples of *Black Hamburg*. Mr. Douglas was first in the class for white *Grapes* with well-grown *Buckland Sweetwater*; and Mr. Lane second with *Foster's Seedling*, bunch and berry good, but the colour wanting. Mr. Bones was first for a *Melon* and also for *Peaches*. There was a good competition in the class for *Strawberries*. Mr. Douglas was first with a remarkably fine dish of *James Veitch*. This is a fine exhibition variety, and the flavour is also very good. Mr. Bones was second with *Premier*. Mr. Douglas was first for a collection of vegetables (eight varieties) all good, the *Asparagus* particularly so. Mr. Monk was first for six varieties; and Mr. Douglas for a brace of *Cucumbers*, variety *Tender-and-True*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PLentifully water *Celery*, plant out for succession, and prick out that from the early April sowing for the latest crops. Continue to provide for successional supplies of *Turnips*, *Lettuces*, *Radishes*, and *Spinach* by occasional sowings, as may be required. Sowings for use in late summer and autumn of early blue and green *Marrow Peas* may be made, also *Early Longpod Beans*. Cut off the tops of *Broad Beans* at the uppermost pods; it will cause the pods to fill more quickly. Complete as soon as possible the thinning of all root crops, and if *Carrots* are wanted for drawing in a young state a sowing may now be made. *Early Horn* and *Nantes* are best for this purpose. Take advantage of favourable weather to plant out *Broccoli*, *Savoy*, and other description of winter *Greens* and *Cauliflowers* as ground becomes vacant. Prick out those for later plantings; they keep and transplant better than from the seed bed. *Early Purple Cape* and *Grange's Broccoli* sow for use in autumn. Remove the seed stems from *Seakale*, cutting to the lowest leaf, and thin the crowns of that planted this spring to one, two, or three crowns to each plant, according to their strength, removing the weakest, so that the crowns left may become large and well developed for forcing purposes. Vegetable *Marrows* and *Ridge Cucumbers* should be

earthed-up, the shoots pegged out, and when the weather becomes settled the glasses removed.

HARDY FRUIT GARDEN.

The stopping and nailing or tying-in of wall trees should be proceeded with as rapidly as possible, laying in a sufficiency of young shoots to fill up or extend the trees. It is well not to pinch-in too closely, or, instead of forming fruit buds, the trees will start into second growth. The cold weather lately experienced has been unfavourable to the growth of fruit trees generally; as a consequence aphids is becoming troublesome, especially with *Peach*, *Nectarine*, and *Plum* trees. Any shoots that can be dipped in tobacco water it is well to so treat, or the trees may be syringed with soapy water, 2 ozs. of soft soap to the gallon. If tobacco water be employed allow it to remain a day, and then thoroughly wash the trees with a syringe or engine. *Gooseberries* and *Currants* should be cut back to two or three leaves of their base; but *Black Currants* should not be stopped, but any unfruitful growths may be thinned. There is every prospect of stone fruits not stoning satisfactorily, therefore we advise moderate thinning. *Pears* have set very badly, and *Apples* are not likely to be anything like the crop the blossom promised. *Plums* and *Cherries* are swelling very irregularly, so there is much doubt of the greater portion falling off ere they attain any size. *Pear* and *Apple* grafts should have had the clay removed and ligatures loosened; if not, it must no longer be delayed. Short sticks thrust into the ground and the scions secured thereto will make them safe, but they will soon have such hold of the stock as to be proof against wind.

Strawberries are abundant alike in fruit and foliage, and are throwing out runners strongly. Especially is this the case with those planted in July last year from which runners are usually had for growing in pots for forcing. It is important that the runners are those of fruitful plants, that the first runner on each wire only be layered, and that it be done so soon as it has a pair of leaves and shows roots at its base. Between every other row of plants place 3-inch pots filled with rather strong turfy loam and a sprinkling of buffalo-horn manure well firmed into the pots without crocking; let the pots stand in single file, half plunged in the soil to keep them in position and more uniformly moist. Make a small hollow in the centre of each pot to receive the runner, cut off the wire just beyond it, and secure with galvanised wire pegs about 1½ inch long. Some employ stones for keeping the runner in position; we find these very indifferent, especially when nets are employed for protecting the fruit from birds. *Vicomtesse Hélicart de Thury*, *La Grosse Sucrée*, *President*, *Sir Joseph Paxton*, *James Veitch*, and *Sir Charles Napier* are admirable for forcing purposes, and are placed in the order of their ripening; *British Queen* or *Dr. Hogg* and *Cockscomb* for late forcing. *Black Prince* and *Keens' Seedling* are also good for forcing, but the fruit is not equal in appearance to the preceding. For outdoor culture *Black Prince* and *Keens' Seedling* are not superseded as first earlies; we also grow *Vicomtesse Hélicart de Thury*, *President*, *Lucas*, *Sir Joseph Paxton*, *James Veitch*, *British Queen*, *Dr. Hogg*, and *Frogmore Late Pine*. In light soils *Vicomtesse Hélicart de Thury*, *Sir Harry*, *President*, *Lucas*, *Dr. Hogg*, and *Filbert Pine* we have found to succeed better than many others.

Ground for *Strawberries* should be trenched and liberally manured, but that manured and trenched last winter will be in good order for planting with *Strawberries* after early *Peas* or *Potatoes* without further preparation than forking over to level the ground. Two feet between the rows and 18 inches in the rows for the moderate growers, and 2 feet 6 inches between the rows and 2 feet in the rows for the more robust, are suitable distances. The plants when detached from the parent may be put in a shady position for a few days, or planted out at once if the weather is moist. They will produce a good crop of fine fruit next season.

FRUIT HOUSES.

Vines.—Keep the house cool and airy, and as dry as is consistent with the health of the *Vine*, and the temperature not less than 60° at night. The *Vine* being a gross feeder when growing should be abundantly supplied with water in dry weather, particularly the surface of outside borders, which in bright cloudless days become dry where no mulching is given, causing the roots to strike deep into the border and drainage in search of moisture. Avoid this by timely waterings and mulching of the outside as well as the inside borders. The nights are yet too cold to allow of fire heat being dispensed with, but the fires should be stopped early on fine mornings, air being given early at top, first in moderate quantity, gradually increasing it as the day advances; and when the maximum is reached air may be given in front, but avoid cold draughts or sudden depressions of temperature, as these are likely to cause rust. Bring to a close as soon as possible the thinning of late *Grapes*, or if not yet sufficiently advanced for that purpose keep up a temperature of 75° to 70° at night, advancing to 85° or 90° by day from sun heat, closing at 80°. In cases of this kind the crop must be forwarded by affording a genial warmth through the summer so as to have the crop well ripened before autumn, as there is little hope of the *Grapes* keeping well and plump without their being thoroughly ripened. Newly planted *Vines* will be growing freely and should have

copious supplies of water, and the borders mulched to keep the roots near the surface. Syringe copiously on fine afternoons and close early, allowing the laterals to extend considerably with a view to the formation of roots.

Peaches and Nectarines.—The fruit will now or shortly be all gathered from the earliest forced trees. Admit all the air possible day and night. If the roof-lights are moveable take them off altogether after the trees have had full ventilation for a fortnight, and keep the foliage free from insects by forcible syringings, and if need be an insecticide. Soft soap 3 ozs. to the gallon of water will check red spider, and if scale be present syringe the trees with paraffin, a wineglassful to four gallons of water, mixing it well and keeping well mixed during application. The borders also must be well watered in dry weather. Cut away the wood having borne fruit to the shoot at the base intended to fruit in its stead next year, except such shoot is required for extension. If there be a superfluity of shoots they are much better removed now than allowed to remain until the winter pruning. Keep laterals and any gross shoots closely stopped. In the succession houses former directions must still be followed, syringing the trees twice a day to keep down red spider, attending to the borders with water, and mulching so as to maintain a good moisture in the soil and to promote surface roots, tying-in and regulating the shoots as required. Remove any leaves that shade or overhang the fruit when it commences ripening, so that they may be equally coloured and the quality enhanced.

Cherry House.—Keeping the foliage dry whilst the fruit is ripening and afterwards to preserve it in good condition favours the spread of red spider. As soon, therefore, as the fruit is all gathered remove the shading material and syringe the trees twice a day until the pest is eradicated, and if there be any aphids annihilate it by repeated fumigations or syringing with tobacco or quassia water. Open the house fully, and remove the moveable lights altogether. Trees in pots may be plunged in ashes outdoors in a sunny situation, attending to them and those in the house well with water as required.

Orchard House.—Cherry trees hardly ever escape being infested with black aphid. As this fastens itself on the under side of the leaves water from the syringe or engine has very little effect upon it, and it withstands more tobacco smoke than will destroy the brown or Peach aphid. Those and the blue aphid upon Plums are best overcome by quassia water or tobacco water, which is rendered more effectual by gently rubbing the infested leaves with the fingers, they being well and repeatedly wetted with the tobacco water. This is best done in the evening, and the following morning well wash the trees with the syringe or garden engine. Fumigations are, however, more readily given, and when persisted in are certain to effect a clearance. It is necessary to have the foliage dry, and not to fill the house too full of smoke, as an overdose is certain to scorch more or less of the tender foliage. The trees should be well syringed the following morning. Syringing trees twice a day must not be neglected, or red spider will assuredly soon obtain a footing, from which it is difficult to free the trees. Attend to pinching the shoots; the side shoots upon the main branches to two or three leaves, and the extremities to six, the leaders of pyramids being stopped to 12 inches. It will now be seen which of the fruit is likely to stone freely, and thinning should be done accordingly. During fine weather the ventilators should be allowed to remain open constantly, excepting when the nights are unusually cold and during the prevalence of high winds, when they should be partially or wholly closed. Attend well to the trees with water, and any that are weak feed with liquid manure.

FLOWER GARDEN.

The recent rains have been of service in settling the soil about the roots of bedding plants, which are now making good growth. Tender plants employed for summer decoration should be got out if not already done, they having been well hardened off, and if the weather be bright at the time of planting a slight shade, as that of evergreen branches, will insure the earlier establishment of the plants. The grouping of subtropical plants requires some taste and skill, making choice of such as associate well together, having due regard to the ultimate proportions of the different plants as to height, &c. Detached or isolated specimens should be bold in aspect and distinct in outline from the groups. Palms answer well, as they are dissimilar to a majority of plants employed for this description of work, also Dracænas. Except in sheltered situations subtropical gardening should not be attempted, as the leaves of many are torn to shreds in exposed situations, and nothing is then so miserable in appearance. The ground for a majority of subtropical plants requires thorough enrichment, which should be given before planting, with a view to as much leaf-development as practicable.

Plant out without delay Stocks, Asters, and other kinds of half-hardy annuals in ground that has been well manured and forked over frequently. Those previously planted should be well watered in dry weather and mulched with short manure. Hardy annuals sown in masses should be well thinned if thick, or they will have a weedy appearance, neither plants nor flowers arriving at proper development. Herbaceous plants require attention in

staking and tying, but better leave them alone than bundling them by running a piece of matting round, as it prevents the shoots from receiving light and air, the stems become long and weak, and many of the leaves are destroyed. If only one stake is employed the branches should be looped up separately, so that each may receive its due amount of light and air to insure full development, besides having a much better appearance. Before staking, the weakest shoots should be removed with a view to the concentration of the vigour in those retained, thereby inducing fine heads of bloom. Hoe the ground frequently to destroy weeds, and rake so as to give a neat appearance.

Roses are fast swelling their flower buds, and when they appear should be liberally watered with liquid manure, mulching the ground afterwards with manure. Violas, Verbenas, Calceolarias, and other plants delighting in moisture or liable to suffer from drought should also have the soil well mulched. Dahlias and Hollyhocks will require stakes. If fine flowers are expected the plants must be well watered. Hollyhocks if wanted for exhibition must have but one stem retained to each plant. Prick out seedling Wallflowers, Antirrhinums, and other biennial or perennial plants. Rhododendrons, Azaleas, and other American plants should have the decayed flowers picked off, which will not only improve the appearance of the shrubs but will increase their vigour.

PLANT HOUSES.

Orchids.—Masdevallias do well in a cold north house or pit for the next two or three months, as when these plants are kept too warm they become drawn and weakly, rarely producing any flowers; they require plenty of water at the roots, the leaves being frequently sponged to keep down thrips. *Odontoglossums* should have air early in the morning, so as to keep a cool temperature and sweet atmosphere. They require copious supplies of water at the roots and frequent syringings overhead, which will keep the bulbs large and clean. Yellow thrips are often troublesome. Sponging is the best riddance, but they often get so far down into the young growth that nothing short of blowing tobacco smoke into them will make them shift. If fumigation be resorted to it must be frequently and carefully done. *Oncidium* starting into growth may be repotted; most kinds require more heat than *Odontoglossums*. *Dendrobiums* must have very liberal treatment, plenty of moisture above and below, so as to secure strong growth, and that well matured will give correspondingly fine flowers. *Anguloas* will now require large supplies of water. Plants of *Calanthe vestita* that have filled the pots with roots may be shifted into larger pots, using well decayed manure and leaf soil; or if not shifted give weak liquid manure at every alternate watering, applying the syringe freely every morning and evening. They do not require more than slight shade. *Epidendrums* require plenty of air and light. *Cypripediums* require syringing and watering freely. They must have the atmosphere well charged with moisture, and liquid manure sprinkled about the house once or twice a week will invigorate the plants. Remove *Miltonias* when the growth is completed to a cool house, and only afford moisture to prevent the bulbs shrivelling. Syringe all East Indian plants frequently, especially on fine days. Any that have grown vigorously and filled the pots with roots should have a shift into larger pots. If the roots are attached to the side of the pot it is better to break the pot, and allow the crocks adhering to the roots to remain, than to injure them by striving to remove the plant from the pot. Those not potted will require a top-dressing of fresh sphagnum. Admit air freely in the Cattleya house, and shade only to prevent burning. If wanted to prolong the bloom of *Cattleyas* and *Lælias* they should be removed to a dry house. Any plants which have their growth approaching maturity should have the moisture about them lessened, and be more exposed to light and air so as to bring them gradually to a state of rest.

TRADE CATALOGUES RECEIVED.

Ewing & Co., The Royal Norfolk Nurseries, Newmarket Road, Eaton, near Norwich.—*List of Clematises.*

H. Bolton, Norwich Nurseries, Wained Road, Nelson, New Zealand.—*General Catalogue of Garden and Farm Seeds, Plants, Trees, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

RHODODENDRON (H. L.).—Rhododendrons are too numerous to be named from seeing a single flower.

PARAFFIN AND ROSE TREES (W. S.).—Diluted (half a wineglassful to a gallon of water) the paraffin would not injure the Roses nor the bulbs.

CAMELLIAS FROM GHENT (Clericus).—Imported plants do not, as a rule, thrive so well as plants grown in English nurseries. Instead of repotting your plants remove a little of the surface soil and replace with a mixture of peat, loam, and leaf soil. See that the drainage is efficient, and water copiously until the buds are set, allowing the plants to remain under the shade of the Vines until the Grapes commence colouring. The Camellias may then be placed in a shaded position out of doors, but not under the drip of trees, placing them under glass again before the occurrence of heavy autumn rains.

VENTILATING VINERY (Amateur).—The top lights of your vinery ought to be opened long before 8 A.M. in sunny weather. Your safe plan is not to close them entirely, and immediately the thermometer rises above 60° in the morning to admit more air. Excluding the fresh early morning air from Vines is a fertile source of red spider, and consequently of unsatisfactory crops of Grapes.

SWEET WILLIAM CULTURE (M. P.).—These beautiful border flowers should be grown as biennials. Sow the seed at once in an open border, sow it thinly, and cover it slightly with fine soil. When the seedlings are large enough to be handled transplant them 6 inches apart and you will have sturdy plants by October or November, when they should be planted in their blooming positions. The advice you have had to sow the seed in August is not sound—that is, if you require strong plants and fine heads of flowers next June.

ZONAL PELARGONIUMS FOR WINTER FLOWERING (X. Z.).—Insert the cuttings now in 3-inch pots; when they have rooted shift them into larger pots as required, growing the plants in the open air, pinching out the shoots until August and the flower buds until October; then remove a portion of the surface soil and replace with rich compost, placing the plants in a light house having a minimum temperature of 45°. Nearly all the varieties flower freely in winter when thus managed, but *Vesuvius* is probably one of the best scarlets for your purpose, and *Madame Vaucher* one of the best whites.

PROPAGATION OF GLOXINIAS FROM LEAVES (Constant Reader).—When you cut off the leaves retain half an inch of leafstalk. Insert each leaf singly and upright in a mixture of equal parts of peat and silver sand in 3-inch pots, placing nearly an inch of the bottom of the leaf in the soil. Bottom heat is not essential. Keep the pots in any shaded position in the same house as the parent plants or in a vinery. Give water regularly, and by autumn you will have a plump little bulb in each pot. If the leaves are very large it is unlikely that they will remain erect after they are inserted in the cutting pots; that, however, is immaterial provided they keep fresh.

PANSIES AND ANTIRRHINUMS DYING IN WINTER (K. J. R.).—Both these fine perennials are quite hardy, but both, like many other of our best border flowers, succumb to the combined effects of cold and excessive moisture. Make your soil light, rich, and very gritty; raise it 9 inches or a foot above the common level, and your subsequent losses will be so few as to be immaterial. Far better is it to do this than to resort to pot culture, involving as it does so much extra care and labour. Instead of growing the plants in pots we advise cuttings being struck in August, the plants being wintered in small pots placed in cold frames and then planted out in the spring.

GRAPE VINES FOR TEXAS (J. H. W.).—All the varieties of the Grape Vine cultivated in this country will doubtless flourish in Texas, as it lies well within the limits of latitude wherein Grapes grow to perfection in the open air. Of early sorts, white or golden, take Dutch Sweetwater, Buckland Sweetwater, Ferdinand de Lesseps, Golden Champaign, Muscat St. Laurent, Royal Muscadine; and of black sorts Black Hamburgh, Frankenthal, Esplan, and Red Chasselas. You ask for early sorts and we have given them. Do not forget, however, that those which we term late would prove comparatively early in Texas; and we strongly advise you to add to white and golden sorts Duke of Buccleuch, Dr. Hogg, Golden Queen, Muscat of Alexandria, Mrs. Pearson, Trebbiano; and to black sorts Alicante, Gros Guillaume, Madresfield Court, Mrs. Pince's Muscat, and Lady Downe's Seedling.

CUCUMBERS AND MELONS DISEASED (M. D.).—The roots, as you state, being perfectly healthy we are unable to account for the diseased shoots and foliage: we are inclined, however, to attribute the injury to some defect in the ventilation or the general management of the atmosphere of the house or frame. On those points you do not afford any data enabling us to form an opinion.

WORKING MEN BOTANISTS.—“A Lancashire Working Man Botanist” writes to us to suggest to other working men who are interested in the study of botany the desirableness of corresponding with each other for the purpose of exchanging specimens of plants from different parts of the country. His address is Mr. W. Henshaw, 64, King Street, Farnworth, Manchester.

VINE LEAVES (A Five-years Subscriber).—They are not diseased, but very luxuriant. Give rather less water, and ventilate more freely.

GRAPES SPOTTED (Muscat).—They are being destroyed by “the spot,” an ulcer caused by defective root-action. If fermenting dung were heaped over the surface of the outside border it might check the spreading of the disease. Pick off the spotted berries, and ventilate freely yet carefully.

PANSIES (J. M. Oughton).—They are fine flowers, but we cannot name florists' varieties.

COMFREY CULTURE.—Your correspondent who is wanting information regarding this useful plant is quite right in covering it with manure. Only recently we had some hundreds of crowns manured, but the manure is never raked off again. It is a strong-growing plant giving heavy crops and requires cutting three or four times each season; horses, cattle, and pigs, all of them eat it freely.

GRAPES DISEASED (A Subscriber).—They are badly attacked by the spot, and well they may be, for two berries out of every three ought to have been thinned out long since. Cut out every spotted berry. There is not sufficient sap supplied to sustain the growth.

PLANTING FLOWER BORDER (R. E.).—We cannot advise, nor can any one without seeing the place.

EMIGRATION (N. D.).—We never venture to advise. Apply to the Commissioners for Emigration.

BUDDLEA GLOBOSA (A Mayo Subscriber).—The honey from this flowering shrub is not injurious either to bees or bee-masters.

GERANIUMS (A. H.).—Florists' varieties are too numerous to identify from trusses of flowers only.

WOODLICE (T. W.).—Put slices of potato in garden pots in your Cucumber house, and cover the potato slices with a little moss. The woodlice will resort to them.

NAMES OF FRUITS (James Beadle).—1, London Pippin; 2, Graham or Deux Ans. (H. C., Framfield).—It is the Tulip Apple.

NAMES OF PLANTS (James Beadle).—The plant is *Asphodelus albus* (W. Ryan).—No. 3 is the Red Valerian. The other two specimens are merely leaves.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION OF THE SWEDISH TURNIP.

(Continued.)

In cultivating the land under a fallow preparation it will depend very much upon the nature of the soil as to the system to be adopted. In many of the northern counties and parts of Scotland the system of drilling on the stretch is common, but this can only be successfully carried out upon the light and finely working soils, such as gravel, sand, or chalk. In the coarser soils the surface will often prove rubbly and unkind, in which case when two furrows are thrown together to form the ridge or stretch it makes a poor seed bed, and in dry weather the seed will not vegetate with regularity. If ridge culture is decided on, the land should be laid into ridges from 27 to 30 inches apart during winter. In the spring the stretches should be split with a double mould-board plough and allowed to lie until the weeds begin to appear, then lay-out the dung and spread into the furrow between the stretches, and if guano is used sow the manure over the stretches, and in either case reverse the ridges with the double mould plough. The manure will then be buried in the centre of the ridge directly under the seed, which should be drilled with 2 or 3 cwt. of superphosphate per acre on the centre of the stretches. This drilling is generally done with a drill for the purpose of seeding two ridges at once with a hollow roller attached. We have, however, when we did not require to apply manure with the seed, drilled it with little hand drills, such as are used by gardeners, and costing 10s. 6d. each. With these a man will seed a good lot of land in a day; in fact we have found women sometimes will do this kind of work. We will now refer to the drilling Swedes on the flat, and many parties prefer it, objecting to the stretches where the roots are to be fed off by sheep, as the animals are apt to be cast on their backs between the stretches and be found dead. Drilling on the flat or wide ridges is particularly adapted to a very dry climate and unkindly soils, like much to be found in the eastern and southern counties, because the seed will vegetate more regularly with a less kindly tilth and with a less amount of moisture, and thus the plants may be preserved until the nights get longer and the autumn rains commence.

The selecting a sort of Swede adapted to the soil and climate and the purposes for which the roots will be required are matters of much importance. Skirving's Liverpool Swede is a very quick-growing variety, and therefore well adapted for early sowing and for pulling at the earliest period for cattle-feeding in the stalls, as we have found the Swede almost the only sort that becomes ripe and fit for feeding bullocks before Christmas. They will, with the application of a liberal dressing of guano and superphosphate, sown side by side with other sorts, be ready first. We have, however, various sorts to choose from for the main crop and general use on the home farm. Nearly all our seedsmen throughout the kingdom advertise their Imperial Hardy Purple-top Swede. Setting the Sutton's Champion Swede next in quickness of growth and best adapted to succeed the Skirving's Liverpool variety, we may then say that the different growths by various seedsmen vary but little as to their nutritious properties. In order to test the advantage of the seed offered by the different seedsmen it should be matter of experiment, because the sorts and qualities are so nearly allied, that the soil and climate and the various purposes for which the roots are required must decide

the question when we come to consider the various matters in connection with their growth and requirements of the grower. There is a white Swede which, being a hybrid sort, cannot always be depended on to produce roots of kindly well-grown shape; yet we have seen sometimes very handsome well-grown bulbs of this sort, and when they can be depended on they are about the best for late sowing and spring feeding. All the Imperial Purple-top varieties offered by the best houses for the sale of seeds may be depended on to furnish a sort to be carried on for use at the latest period, if the cultivation and time of sowing have been arranged with the view of retaining the roots in full feeding value at the latest period in the spring. Still this is not so important a point except on certain soils as it used to be, for mangold has stepped in and says, "Hear me. I have more nutriment than the Swedish turnip, and I have more weight per acre to give you," but the advocates of the Swedish turnip reply, "Yes, but we must go to the expense of pulling, carting, and storing the roots of mangold, whereas the Swedish turnip may be allowed to remain on the land when it is desirable that our breeding flocks of sheep should be enabled to feed them upon the land in open-field feeding at the least expense." We have next to consider how this (to the flock masters) desirable object is best and most economically to be obtained. Now although the nature of the soil has much to do with this matter, yet we are brought to the question of considering the best time for sowing. We will put it this way:—If Skirving's Swedes are required for early feeding, the 20th of May is not too early sowing, particularly in the northern and midland counties. If the crop is required for general purposes, the first week in June is the best seed time for the hardy Purple-top varieties. If, however, the roots are intended for late-spring feeding either the white Swede or the Hardy Purple-top may be sown from the 25th of June to the 1st of July, with the full assurance that they will be after ordinary winter weather found to possess full feeding value in the spring months. Much, however, will depend upon the soil, for a farmer with whom we were well acquainted did not sow his Swedes until he could obtain new seed of his own growth of the same season, and he doggedly pursued this plan for forty years with the greatest success; for after having often gone over this farm for a long period we can safely say there was no farm in the district which gave a better crop than the one alluded to, although it often happened that the seed was not sown until the first and second week of July. It was a sharp gravel soil, in a fine salubrious climate, and well farmed, which not only insured the quickest growth, but the growth at the latest period, and often extended into the winter months.

As drilling on the flat is the most general mode of cultivation we shall therefore consider that if the weather is very dry it may be bad policy to plough the land just before drilling, but to scarify instead, which will destroy the weeds without losing the moisture so essential towards vegetating the seed. The manure to be applied must to some extent depend upon the state of the land previously, because if the ground is full of manure from former cultivation 3 cwt. of superphosphate per acre with a few ashes, or fine chalk, will prove an ample dressing. On the other hand if the land is poor 2 cwt. of Peruvian guano may be applied per acre, but not with the drill, as we have known it kill the seed, and therefore prefer to sow it broadcast after the plants are strong, and horse-hoe immediately afterwards. If it is sown broadcast when the seed is drilled it encourages the weeds without benefiting the young plants in the same proportion. In deciding upon the distance at which the seed should be drilled, after many years of experiments upon this point we prefer 20 inches between the rows, and leaving the plants at 15 or 18 inches apart in the lines, according to the nature of the soil, the only exception being on land more than usually subject to annual weeds. It is best then to drill the seed at 24 to 27 inches between the lines in order to facilitate horse-hoeing, and at this distance the plants may be left closer in the lines so as to obtain not less than 120 plants to the rod. We like to drill about 2½ to 3 lbs. of seed per acre, as this not only allows for destruction by the enemies such as wireworm, grub, and fly, but the plants grow faster in their infancy when thickly seeded. With respect to hoeing we have often, when the plant has been thick and regular, been induced to horse-hoe across the drills and to set the hoe at 12 inches wide, which will leave the plants in bunches at rather more than that distance apart. The labour of hand-hoeing is thus diminished and the plants may be singled by hand by women. It is, however, most essential at the time of hand-hoeing and singling the plants always to leave the strongest plants, and this point is more to be regarded than any little difference in the distance between the plants. We shall omit any remarks at present as to cultivating for Swedes as a second crop after trifolium, vetches, &c., because this matter will be treated of under the cultivation for common turnips in a future article.

WORK ON THE HOME FARM.

Horse Labour.—This still consists of preparing the land or drilling the seed, also with the necessary work of harrowing, rolling, &c., for the different root crops. In some instances it has

been very difficult to prepare the land in due season for mangold and Swedish turnips owing to the continuous rains in the past month of May. We have, however, had four or five dry days, which have enabled parties to get in the mangold to prepare for the drilling of Swedes. The late showery weather which prevailed during the month of May has not been without its advantages if it has had drawbacks, for wherever it is intended to sow Swedes or turnips after green crops, such as rye, trifolium, vetches, &c., the land is now soft and kind for roots at one ploughing. This is favourable when compared with some very dry seasons, when it is difficult to plough and work the land to a fine tilth so necessary for the success of root culture. We have land now which we could not drill with mangold until the present week on account of the succession of showery weather; but we do not despair of obtaining a good average crop by the use of a liberal dressing of superphosphate and guano, say 3 cwt. of the former and 2 cwt. of the latter; for although, if we were to judge by the day of the month, it is considered late, yet mangolds are not like Swedes—they rejoice in warm weather, whereas Swedes will flourish and grow when the temperature is lower if moist. We can remember having on former occasions not having sown mangolds until after the 1st of July upon land where we had previously taken a crop of clover, and we have grown as much as 26 tons per acre when the season has been favourable and moist enough to vegetate the seed, and in the case of late seeding we always soak the seed for forty-eight hours in order to insure a quicker start. Cabbages now should be planted for the autumn and winter use, and three sorts are required to complete the succession. The Oxheart comes in first, or otherwise the Imperial variety, then the large Champion cattle cabbage, but for the latest feeding we like the Drumhead Savoy, for they will not only keep long without splitting, but they are the most nutritious for the ewes at lambing time, or for milch cows. When we compare the advantage of planting cabbages after a green fodder crop with the risks of seeding for a crop of turnips, we not only insure a crop of more value but of more certainty, because in the planting of cabbages if set with the spade it matters not if the plants are old and long and strong in the stem. They are sure to grow let the weather be ever so dry, and they grow away at once—very different from turnips, which often require a month or five weeks before they can be finished hoeing and the crop assured.

Land Labour has lately consisted of hoeing peas, beans, and barley, for on some soils unless the barley is drilled at 10 or 12 inches apart the charlock, the poppy, and other weeds will predominate and seriously injure the produce. The drilling at this width does not by any means diminish the crop, but insures a better malting sample, and the best management we have noticed on even the thin chalk soils has been to drill this crop at the widest distances. This is a very important time for all farms whereon sheep are kept, particularly when we consider how difficult it has been lately to get the wool dry enough to venture at shearing. We know various cases where the animals had been washed in order for shearing, but it was delayed in consequence of the succession of wet weather.

This is the important period for shepherds, as it is the time on the hill farms for weaning the lambs, and it should be noticed that it is better to remove the ewes from the lambs than to take the lambs away from the ewes direct to a strange pasture or another field. The labour both for men and women should now be forwarded in order that all hands may be ready for the coming hay season, for although machinery both in cutting and making the hay is an excellent substitute, yet there is always some hand labour required. The odd horse or horses will be required to bring home green fodder for horses, cattle, and pigs. The young cattle, both heifers and steers, whilst feeding on the pastures at daytime will do well at this time of the year, but they should be housed at night time, and an old barn is famous quarters for them, to be fed with a little clover or border grass. They will not only do well with little or no cake, but they will leave a large quantity of valuable manure if bedded with earth and straw.

THIS SPRING'S POULTRY REARING.

Has this been a good or bad season for poultry rearing? For my part I never took more trouble with them or met with more disappointment. Out of nearly 300 eggs set about 140 hatched, and of the 140 chicks only about 90 are living, and many more are likely to go. Most of them have died from gapes, but now there are many dying from some other cause, mostly those about six weeks or a month old. They droop their wings, or in some cases the feathers stand out, the chick looking like a round ball; some remain in this state for days, others go off in twenty-four hours.

The bad hatching I do not think so much of, as they were mostly very early sittings, and at one time several hens deserted their nests from some cause I was unable to account for, but those hatched ought to have lived, as far as I can see. They had everything to make them comfortable. The coops, which are dry and roomy, are placed in a row at the top of a grass field facing south; the grass kept short cut for some yards in front of the coops, the floors of which are kept clean and covered with a mixture of road

grit, ashes, and lime—very dry; also sprinkled often with carbolic powder. The only water given is strongly impregnated with camphor, as recommended in the Journal; the food (crushed oats) boiled and afterwards worked-up with barleymeal, to which is added before boiling a handful of millet seed. On cold days I sometimes give boiled rice with plenty of pepper, and now and then sulphur in the meal. Lately I have given wheat once a day.

My breed is mostly Indian Game, but the mongrels are taken quite as often as the others. I have also given some camphor pills, but it did not seem to cure the gapes.

I should be glad to have the defects in my management pointed out, both for my own sake and for the benefit of any other poultry fancier who may be in the same trouble as myself.—R. TEAGUE, *Sanders, Dartmouth.*

THE PARIS POULTRY SHOW.

THIS great Show of cattle and poultry, of which we have by anticipation talked, written, and surmised so much, was on Sunday morning last opened to the public. Considering the vastness of the Exhibition grounds it seems unfortunate that room should not have been found within them for this Show too, so that all who flock to the world's wonder for this year should have an opportunity of seeing the advances made in the inmates of the farmyard without paying an additional franc. However, putting aside this disadvantage, the ground laid out for the Show is admirably chosen; it is the Esplanade des Invalides—viz., the great space intersected by broad roads and well covered between with trees, which stretch from the Seine towards the great gilt dome. It is converted into a vast show yard. The central avenue is tastefully filled up with green lawns, the marvellous growth of this year, which, like those in the Exhibition grounds, are perfectly astonishing, interspersed with bright flower beds and gravel walks. Stretching far on both sides are the cattle sheds, admirable structures for their purpose, with broad central walk, and two rows of stalls on each side open towards the sides, with excellent roofs reaching well beyond the stalls. They are of wood with ornamental eaves, and remind us of Swiss railway stations.

But we must hasten to the poultry. They are all amongst green avenues in large pens, with one upper and one under tier. The long rows of these pens stand back to back with a passage between, accessible from locked doors at each end. They open into the passage but have no external door, so that it is impossible for the Judges to handle the birds. Above they are covered with marquee-like awnings, but are open to the sides. This arrangement struck us as admirable for this time of year. The awnings are by no means unnecessary, for our fitful English weather seems to extend across the Channel. Half hours of broiling sun are succeeded by premonitory whirlwinds of dust, quickly followed by drenching showers and hurricanes of wind; still these pass off as quickly as they come, and all Paris seems intent on enjoying Whitsuntide. We have seen the bright city in the *fiête* time during the palm days of the empire, but we never saw the crowds of Sunday and Monday surpassed or equalled. But to return to the showyard. The poultry jury entered upon their duties on Friday morning at the same time as the juries for cattle and sheep. Much time was taken up with formalities, an address from the President of the whole section, and other preliminaries, which to the English mind were a little *de trop*. The poultry jury was divided into four sections. The first comprised Messieurs Lagerotte (Deputy), Broquette, Edoux, and Mannechet, who took the Crêves, Houdans, La Flèche, and other French breeds. The second, Messieurs Malazieux (Deputy), O. E. Cresswell, M. Leno, Gindre-Malkerbe, Léville, and Winrion (Inspector of the Jardin d'Acclimatation); they took the Cochins, Brahmas, Dorkings, Spanish, Breda, Hamburgh, Game, Malays, Dutch (White-crested Polish), Paduan (Coloured Polish), and other varieties. The third section, Messieurs Geoffroy St. Hilaire (Director of the Jardin d'Acclimatation), Hauet, Bénion, and Boucheron, who took the Pigeons. The fourth, of Messieurs Dronne, Gayot, Pietrement, and Pono, who judged the Turkeys, Geese, Ducks, Guinea Fowls, and Rabbits.

"The organisation of this country is so great that all is confusion," said Mr. Cunliffe-Owen, the indefatigable Secretary of the British section, to us *en route* to the Show on Friday; and there is great truth in the observation, for so many are the forms to be observed that, though the judging began on Friday morning, no awards were put up or published by Sunday night. We will, therefore, postpone all criticism of them until we have seen them officially printed. The judging was done with open catalogues, and there is no secret that the two English Judges much disliked this method, and were consequently sorely dissatisfied with the result; their patience, too, was greatly tried by the way in which their French colleagues went and came, and in which the decisions made after long discussion were subsequently upset and altered by gentlemen who had not been present at the real judging. Mr. Cresswell, acting as interpreter, made frequent and, as far as courtesy would allow, energetic protests against this course. To take a general survey of the Show, the French classes are enor-

mous and their quality mediocre. A Crêve cock of the Messrs. Fowler and some Houdan hens from Mrs. Vallance struck us as far distancing the native birds. In Cochins, again, English birds seemed ahead in every class. In Hamburghs, Game, and Game Bantams (shown together), and Dutch (White-crested), can hardly be beaten. In Paduan (Coloured Polish), however, our neighbours are before us, and show some charming pens of Buff birds and one or two of White.

The prize of honour has been awarded to Madame Lemoine as winner of the greatest number of prizes, and no wonder, for her entries are over one hundred in number. Gold medals for fine collections were in addition decreed to M. Breachet of Paris (who came second with 88 points), M. Marois (77 points), Messrs. J. K. and R. R. Fowler (57 points), Mr. Beldon (55 points), and Mr. Martin (44 points).

H.R.H. the Prince of Wales honoured the Show with his presence on Saturday afternoon while the judging was going on, and the English Judges were severally presented to him. In addition to the two English winners of gold medals Mr. Darby sent a splendid though less numerous collection of birds. The whole of the British feathered stock are under the special care of Mr. Fowler of Aylesbury, who seems never absent from his post. Thousands flocked to the Show through Sunday and Monday. We hope next week to give further detail concerning it.—C.

THE BATH AND WEST OF ENGLAND SOCIETY'S SHOW.

THE Spanish classes were well filled, but the majority of the birds were not in exhibition form. Cocks.—We did not like the winner; he had a crooked neck, which entirely spoilt his carriage. The second was a coarse-faced bird with a large lobe; we should have placed him in the first position, and Pen 3 (Ball), a smart young bird, second. Hens.—First had a nice-shaped lobe, and was well shown; second, the White, was of very poor quality. We liked Mr. Jones's, Pen 16, much better; it was as large in face, the shape of the lobe was good, and the quality of white much better. *Dorkings*.—First a grand bird in good condition, and sound in feet and comb; second an older bird. Hens.—First large but out of condition, and not so good in shape as the second. Silver-Grey cocks a good class; the first and second were fine birds, but the winner was very striped in the hackle, and we think for this reason their positions should have been transposed. Hens.—Here we thought the second larger and better in shape than the first. White or Blue a very moderate lot. The winner was ugly in comb and shape; second a Cuckoo, small but well marked. Pen 66 we thought contained the best White in the class, but so dirty we considered the Judge quite right in passing him. A hen in the next class belonging to the same owner doubtless lost place in the prize list for the same cause. *Cochins* (Buff cocks).—The winner was a nice bird, and deserved his position; second was small, and we did not like his variations in colour. Pen 78 a good bird, sound in colour, but comb over. Partridge cocks moderate. Hen.—First large; second well pencilled, but deficient in leg feathers. White cock.—First a grand bird, very pure in colour, and in fine condition. Pen 131 (highly commended) was very nice but small. Hens were inferior to the cocks. *Brahmas* (Dark cocks) a very poor lot. First small; second was very creamy in saddle and white in tail. Hens better. First well pencilled, but deficient in leg feather; second also nicely pencilled. *Light cocks*.—First a well-shaped bird, beautiful in colour, with an ugly comb; second a good bird. Hens, with the exception of the winners, poor. *Game*.—The winning Black Red cock was much admired, being beautiful in colour, very stylish, and in superb condition. *Hamburghs*.—In the Spangled classes the Golden cocks and hens only numbered five against seventeen Silver, and in the Pencilled the Golden predominated to the same extent. *Polish*.—A White-crested Black hen first deserves special notice. *French* were well represented, the Crêves in quality we thought the best. Special prizes were given for *Langshans* by H. G. Herbert Morrell, Esq., which produced the large entry of eighteen cocks. We presume the Langshan exhibitors would call it treason if we described them as bad Black Cochins, but we are convinced had they been exhibited as Cochins we have no judge who would have disqualified them for being entered in a wrong class, and *vice versa*. Had acknowledged Black Cochins been entered, as on other occasions, as Langshans the Judge could not have discerned the difference. The chicken classes were largely supported. A well-grown Light Brahma pullet, veryulture, obtained the cup. Many old birds, we regret to say, were shown as chickens, and we were sorry the Judge did not mark his disapproval by disqualification. *Bantams*.—The Sebrights were a splendid lot, every pen being deservedly noticed. The Blacks were also excellent. Two pens of White only competed. They were both good. Game Bantams were not equal to the former classes.

Pigeons.—Many of the classes were very badly filled. In Black Carrier cocks the first prize was withheld, the best bird being put out of competition through a deformed toe. Hens only two entries second prize withheld, one of the competitors showing

white feathers in the vent. Pouters and Trumpeters also contained but two entries. In the latter class the prizes were withheld on account of condition. The Dragoon classes were small, but all the specimens good. In the Jacobin class the winner was broken in the hood. We preferred the second pen. Tumblers were a nice class. In Owls the winner was very much out of condition.

JUDGES.—Poultry: Mr. E. Hewitt. **Pigeons:** Mr. W. F. Esquilan

BEES TAPPING FLOWERS.

IN the *Journal of Horticulture* of the 6th of June Mr. Pettigrew raises the question whether hive bees do or do not tap the flowers of beans. From my own observation I can testify that they do perforate the blossoms for the sake of obtaining the honey. There is a large field of winter beans near my house, and I observed bees making holes in the blossoms near the stalks and visiting flowers which had previously been pierced. Some of the bees were working at the mouths of the blossoms (I presume in quest of pollen), but I never saw a bee which was so engaged on one flower subsequently attack the other end of another blossom; the same bee invariably seems to pursue the same tactics. In the field in question nine out of ten blossoms seemed to be pierced, but in a field near Malvern I could not find a single bean blossom which had been thus treated.

Mr. Pettigrew seems to find that hives which are two years without swarming are liable to be attacked with foul brood. This is not my experience. I have kept bees for twenty-three years and have subjected many hives to much manipulation, but foul brood has never made its appearance in my apiary. My oldest Stewarton colony is four years old, but the bees are perfectly healthy and the combs are not overlaid with pollen.—J. E. BRISCOE, *Albrighton, Wolverhampton.*

THE BEE SEASONS OF 1877 AND 1878.

ALTHOUGH the early part of the month of May gave promise of early swarming and early honey harvests bee-keepers were soon undeceived, and entered upon the most trying season of the year to their pets and to themselves. From the 6th of May until the 30th in this neighbourhood we have had but two or three days on which the bees could store a few ounces of honey. Several of my friends have remarked, "What a trying time for the bees!" but upon reference to my apiary notes of last year I was surprised to find how the seasons repeat themselves. Flowers of all kinds were certainly a fortnight earlier this spring than they were last year, but this was owing to the milder weather in March and April—indeed to the unusual mildness of the whole winter; at the same time the weather and its effects upon the bees were identical this May with what we experienced last year. I thought that a few notes from my diary might be interest-

ing to those of your readers who have not themselves taken notice of this fact.

1877.	1878.
May.	May.
8th to 13th.—S.E. winds; cloudy; no work done.	8th.—Rain all day.
13th & 14th.—S.W.; rain and wind; bees prisoners.	9th & 10th.—Cloudy and E. winds.
16th to 20th.—Wretched weather; rain with gales of wind nearly every day; fed several hives.	11th & 12th.—Showery; bees at work a little between showers.
21st to 24th.—Gloomy, cold, and windy; N.E. winds and no sun; bees killing off brood; whitethorn and cherry blossom blackened as soon as it unfolds.	13th.—Showery and very windy; S.W.
26th.—N.E. wind, gloomy, and cold.	14th to 19th.—N.W. and S.W. winds; very windy and wet; violent squalls and thunderstorms.
26th.—Calm, E. wind, very cold, gloomy.	20th.—Stormy and much colder.
27th.—Wind changed to W., warmer, gale to westerly noon and heavy rain.	21st.—Violent storms, thunder and hail; bees deserted three supers which they had entered three weeks ago.
28th & 29th.—Stormy windy days; bees get out a little between showers, many to perish, washed down by heavy showers. Fed all hives; bees are numerous and lie up in supers over the zinc sheets, but cannot get to work.	22nd.—Showery and cold.
30th.—Storms of wind and rain, but much warmer.	23rd.—Fed all hives; rain until 12 o'clock, then warm and fine.
31st.—Warm; bees out en masse.	24th to 26th.—Stormy days with gleams of sunshine.
	27th.—Thunderstorms.
	28th.—Warm and showery.
	29th.—Weather most miserable—cloudy, cold, N.E. wind.
	30th.—N.E. wind; cloudy but warmer.
	31st.—S.E. wind, clear and warm; bees hard at work and honey being brought in.

The following is a copy of my notes from May 1st of this year, showing the effects of the weather on a hive of bees which hangs from a Salter's balance.

Date.	Weight.	Loss.	Gain.	Remarks.
	lbs. ozs.	lbs. ozs.	lbs. ozs.	
May 18	55 0	—	—	Windy and rainy.
" 20	51 8	4 8	—	Showery.
" 22	49 8	2 0	—	21st, wet; 22nd, showers, finer P.M.
" 23	50 0	—	0 8	Fine until 2 P.M., then thunderstorm.
" 25	50 0	—	—	Showers and sunshine.
" 26	51 0	—	1 0	Fine A.M., showers P.M.
" 27	50 0	1 0	—	Heavy thunderstorms all day.
" 28	50 0	—	—	Showery, but warmer; hive very full of bees; super (weight 7 lbs.) put on after weighing.
" 28	57 0	—	—	Cold, N.E. wind; cloudy all day.
" 29	55 8	1 8	—	Cloudy, but fine and warmer.
" 30	56 8	—	1 0	S.E.; calm; beautiful sunny day.
" 31	59 0	—	2 8	

The above shows that in a fortnight the hive has lost in weight 4 lbs.—P. H. PHILLIPS, *Offley Lodge, near Hitchin.*

REMARKS.

5th.—Dull morning, showery afternoon, fine evening.
6th.—Cold cloudy morning, sunny afternoon, bright and warm.
7th.—Fine in early morning, dull and cloudy between 8 A.M. and 1 P.M.; fine and pleasant the rest of the day. Bright meteor seen in S.W. at 9.52 P.M.
8th.—Close dull morning, heavy rain in afternoon, thunderstorm from 4.30 P.M. till 4.55; fine evening.
9th.—Fair day, cloudy and dull at intervals. [fine bright evening.]
10th.—Fine morning, sharp shower and thunder between 1.30 P.M. and 2.30; fine and pleasant the rest of the day.
11th.—Heavy showers with intervals of sunshine during the day; high wind. Rather finer than previous weeks, but still damp with heavy showers.—G. J. SYMONS.

SEASONABLE NOTES ON FRUIT-TREE INSECTS.

AMIDST the many troubles, anxieties, and annoyances against which gardeners have continually to contend few are more annoying or more difficult to deal with than the hosts of insects which are so liable at all times to infest fruit trees. About this period of the year, when the young shoots and leaves are tender and sweet, few trees escape some insect or other, and many are blighted so extensively that the following season will not see their entire recovery. Very often fruit trees under the care of the very best of gardeners will become infested with insects, although everything imaginable may be done to keep them clean.

Dry weather is generally supposed to be favourable to the rapid increase of all kinds of fruit-tree insects, but wet weather seems to favour many of them just as much, as this season we hear from many parts that insects are unusually numerous on fruit trees, and certainly they have been washed often enough with rain lately. In small gardens Gooseberry and Currant bushes very often form the principal bush-fruit crop. Caterpillars are the most troublesome pest that attacks them. Very often they strip the bushes entirely of their leaves just when the fruit is about half swelled. When this occurs the fruit ceases to swell, the crop is lost, and in many cases the bushes never recover. We have some hundreds of Gooseberry and Currant bushes, and we rarely lose that number of leaves by the caterpillar throughout the whole year. Our means of checking their depredations can hardly be called a remedy or cure, as it simply consists of a little forethought. Whenever a leaf is noticed to have been touched by the caterpillar the whole bush is looked over and every one caught and killed. In this way they never make any headway, and when they are caught before they are numerous it does not take long to kill every one of them. Of course, if they are not caught until the bushes are half consumed it is no use trying to gather them then, because they are too numerous and increase too rapidly. This is the only plan we adopt to keep all our fruit trees free from caterpillars, and the vegetable quarters are kept clean in the same way.

I have no doubt many of your readers will have noticed that wall-fruit trees are much more liable to become infested with insects than standard bushes, although the latter are affected in some instances. Green fly is one of the worst insects that infest Cherry, Plum, Peach, and Nectarine trees. It is not so bad on Apples, Pears, and Apricots. Here, again, it is a great advantage to begin checking the pest in time. It is a simple matter clearing green fly when this is done before they have time or are become so numerous as to curl the leaves, but when they are allowed to do this it is a most difficult matter to cleanse the tree. Immediately green fly is observed on any fruit tree a good handful of tobacco paper should be placed in a pan with five or six gallons of water, allow it to remain there for an hour, and press it occasionally with the hand

to take all the juice out of it. This makes the water the colour of porter, and if the affected parts are thoroughly syringed with this the fly will make no further progress. When a lump of Gishurst compound is mixed with the solution it kills red spider and thrips, and checks blight as well; in fact, tobacco water mixed in this way is one of the best of insecticides, and every person who wishes to have fruit trees free from insects should use it. When the leaves are so badly curled that the water cannot get into their centre, a little of Pooley's tobacco powder should be dusted over them and be allowed to remain on for a couple of days, when it may be syringed off with clean water, and in nine cases out of ten the fly will have disappeared. When the trees are blighted as well as infested with insects a quantity of flowers of sulphur should be mixed up with the other ingredients, and it is a good plan to use a little of this for red spider as well as blight.

Apricot trees are generally very free from insects, but there is one troublesome little one often pays them too much attention; this is a little white worm, grub, or caterpillar. It is generally surrounded with a fine spider-like web, and the leaves curl round it and become perforated at the same time. Pressing all the folded leaves firmly between the finger and thumb kills the maggots, and when they are on the points of this year's shoots the points may be cut off and burned. We are often pestered with large shell snails crawling up our brick walls and eating holes in the sides of the Peaches, Nectarines, and Apricots about this time of the year. This spoils the fruit, but we never have many fruit destroyed in this way, as we look over the walls frequently and kill all the snails we can find. I do not know of a better prevention than this.

As a rule it is the young shoots, or their points, that are attacked by insects of any description, and it is a good plan to attend well to cutting-in these, or what is termed "summer pruning." There is another excellent means of keeping fruit trees clean and healthy which I must not forget to mention. In hot dry weather the roots should have copious supplies of water, and when the ground over the roots shows signs of cracking it should be covered over to the depth of 4 inches with half-decayed manure.—A KITCHEN GARDENER.

QUILL BUDDING.

Now that the Rose-budding season is approaching I really must say a word on behalf of this practice. What I would suggest is to use a quill instead of a knife when the pith has to be extracted; by this the process is very much easier and more successful. I do not write, of course, for professionals, but for amateurs, especially those beginning or ending. I will answer for beginners finding it much easier to get the wood out in this way; also for failing eyes the plan has its attractions. A friend of my own, a determined Rose-rearer, but not as young as he had been—whose better half had the further advantage of being twenty years younger—was accustomed, after taking off the buds, to hand them to his wife; he could not see to accomplish the further manipulation. I do not bud on a large scale, but

No. 899.—VOL. XXXIV., NEW SERIES.

I would say *Erperto crede*. My experience since 1864 is all in its favour. I never think now of preparing a bud in any other way.

I am quite prepared for the fate which these rash remarks will probably bring upon me. I have not forgotten the burst of Homeric laughter which greeted me when I ventured to propound this theory in the pages of our Journal in December 1874. Said my friend Mr. Hubert Bensted—(may his shadow never be less and his success at the National every year more)—“Necessity compels me to carry a toothpick, but for the purpose its name denotes: certainly not as an aid in the operation of budding.” That is a very fair criticism, but possibly I shall find someone who has also adopted this plan to support me in advocating it. At any rate I plead for the giving it a trial. As the imperilled Athenian said, although not exactly under similar circumstances, “Strike but hear!” So I would adopt—Laugh but listen, triumph but try!—A. C.

THE ORCHARDS OF HEREFORD AND WORCESTER.

(Concluded from page 424.)

2. THE next cause that acts so much to check English fruit-growing is the foreign importation. Of course fruit from abroad is landed in large consuming towns and close to railways, so that it can be easily and cheaply distributed over the country. Nobody would deny that we could produce fruit enough for our own use, and the question arises whether, for the sake of removing a very slight addition to the immediate cost of an article to the public, it is worth while to persistently discourage an excellent industry, pay our money into foreign pockets, and reduce employment for our large population. Depend upon it the fourpenny loaf is well worth fivepence to the English labourer if entirely grown in his own country. Let us be only reliant and self-supporting. Besides, if English fruit-growers had really a fair chance English fruit would soon be as cheap as foreign supplies.

It is well known that the diseases which foreign cattle bring in with them destroy more English meat than they supply. The importers of foreign cattle possess by their wealth an improper influence, and the importers and dealers in foreign fruit to some extent the same. “Why,” says a writer on English agriculture, “do we not turn fruit-growers? I was in Covent Garden Market yesterday, there were £20,000 worth of fruit, and it was all from abroad.” Every year we had articles in the papers on this subject. The chief reason why this cultivation is not increased is because there is no getting a fair price for the produce.

When a Worcestershire farmer travels to Manchester or London in the vain hope of selling his large stock of splendid fruit, he is told that foreign fruit can be got so cheaply that he cannot be offered anything worth his acceptance. What is the consequence? The farmer goes home disgusted, five or six extra men hand-picking at 2s. 6d. a-day are dismissed, and the fruit is either made into cider or devoured by the sheep and pigs. At rent day, when the farmer meets his landlord, he cannot pay all his rent, his farm being valued at, perhaps, 10s. per acre all round over its corn-growing value for the fruit that is supposed to be sold off it.

Then as to labour. A few years ago there seemed no certainty at all as to where the demands of the agricultural labourers would stop, and farmers all turned their attention to methods of making money without need of labourers. Of course to market a crop of fruit takes labour, and that of an expensive kind. Had the movement continued the English labourer might soon have found himself out of employment altogether; and although wages were raised to the highest pitch five or six years ago, Worcestershire farmers have never since reduced them. Still, the attitude of the labourers caused terrible mischief, and has in these counties conducted to the present lamentable state of agricultural affairs.

No doubt we have improved, and that enormously, in our stock-raising. Every farmer now knows how to fetch fat mutton into the market at ten months, and fat beef at twenty months old, which sort of supplies, though inferior to what are raised naturally, pay well, and in this we beat our forefathers altogether. But, alas! for the ploughed land. Will anyone look at our fruit-growing districts and say if there is any improvement here? Where are the crops of Wheat and Beans that were grown forty years ago? Where is the workmanlike clean appearance of the land, and where are the workmen? We must be growing less and less corn every year.

3. And this brings us to the last cause we will mention of

the deterioration of our fruit-growing. Certainly in this district all farming except stock-raising is going backwards, and at the same time we are trying to make ourselves believe it is quite the contrary. Landlords in this neighbourhood have determined to have the land farmed on what is called the “high” system, and they want to help both themselves and the farmers by reducing labour. Trees wherever planted are of course an obstacle to the use of machinery, but the system of farming, which no doubt answers well in the Lothians of Scotland and on the broad plains of Norfolk, will never succeed in such a neighbourhood as this. The whole formation of the country and the character of the soil are against it. It by no means follows that old-fashioned farming is bad farming, and although numberless improvements have been made in detail, it is certain that the cultivation of the soil in this neighbourhood is not so profitable to the farmer, the labourer, or the country at large as it used to be.

No greater mistake is being made than that of the land-owners in discouraging fruit cultivation, or perhaps, rather, not exerting themselves to interest and improve it. Every farm should be well inspected with regard to its fruit-growing capabilities. Orchards that are half-stocked with trees should be planted up and kept planted up. Tenants should be bound to plant a new tree for each one that comes to an end. The green orchards which are almost worn out should be either entirely planted up or entirely rooted out. A farmer is often losing weekly £5 worth of dairy or other produce for the sake of a pound’s worth or so of fruit that is not fit to be gathered. An orchard should be well worth shutting up altogether when necessary, and by taking care no inconvenience will be occasioned. It is easy to eat down the orchards bare and let the open land grow up till the middle or end of August.

Straggling trees all over the farm are a great nuisance on this account also. Cattle thus get a chance of tasting the fruit, and they often, especially in a dry season, get such a “hankering” after it that they cannot be safely confined in any field by any fence. A dairy of cows turned into a field of splendid keep, after being brought back from their “fruiting” will not put their heads down to eat for hours together.

Why we bring our Wheat from Russia and our fruit from America, leaving agriculture in our own land to go downhill and the country generally to be ruined, is a question to which economists might well apply themselves. Our soil is probably not above the European average, but, on the other hand, we have more capital than any other country, and we have far more knowledge of how to apply this capital to agriculture. Were this surplus capital put into our own soil, and those branches of agriculture encouraged which feed most and employ most, we should find ourselves at times like the present in a very different position. Why, it is said that the troublesome little state of Servia can put more men into the field than we. Vegetarians will be interested to know that the only branch of industry in that country is Plum-growing. There can be no doubt that by increased attention to fruit-growing in England a great deal more useful wholesome food would be produced and many more people employed. Of what use would be tons of gold and silver in the Bank of England if foreign produce were prevented by any reason reaching our shores?

It is satisfactory to turn for a moment from the Apple and Pear cultivation of this district, which is certainly either at a standstill or going downhill, to that of Plums, Gooseberries, and Currants, carried on so extensively in the neighbourhood of Pershore. Enormous plantations of the white *Magnum Bonum*, commonly called the Pershore or Egg Plum, are there to be seen, and it is difficult to know when market gardening ends and farming begins. One holding of two hundred acres is entirely devoted to Plums and Gooseberries, with the exception of a few Pears, and is well worth going a long way to see. On an average this garden is very profitable, but the losses some years are of course very great. It was planted by Mr. Varden, an engineer who was employed in the construction of the Great Western Railway, and who was so much struck with the Pershore system of cultivation that he devoted himself to it on this scale. Since his death it has been bought by Mr. Bomford, who farms about three thousand acres besides.

Along the Teme valley are many valuable Cherry orchards, some of which bring from £10 to £15 an acre annually to the farmer without expense on his part, the crop being sold on the trees by auction or otherwise. Cherries should invariably be planted together, and as thickly as possible, as it is necessary

for some weeks before they are gathered to have a man living in the field to scare the birds.

Damsons would be more cultivated were it not for the difficulty of getting women to pick them. A woman must work hard to pick a pot in a day, and there are fewer women to go to work now than formerly. Damsons fetch as much as 3s. a pot in some good years, and are always saleable on account of being used for dyeing purposes. Plums here in a very abundant year can hardly be got rid of at all. Damsons, of course, do better on light soils, but they thrive well along with the Apples and Pears.

ROSE SHOWING.

"ONE thing more—one more delight I must mention, and that is the delight of giving away the prize Roses. Send to those who have not any. During the rest of the season help one of the flower missions. If you so much enjoy those splendid flowers about your drawing-room, think of the brightness they must shed round the sick ward of the hospital! Let these lead them—have they led us?—to thank the Great Giver of all good things. That is to carry love of Roses beyond the world."

So Mr. Cheales ends his pleasant little article on "Rose Showing" in the "Rosarian's Year-Book" and with the great Rose shows approaching on the one hand and hospital Saturday and Sunday on the other, the thought occurred to me whether those who love the Rose and who grow it in such perfection could not, without loss or inconvenience, do something in the way suggested by Mr. Cheales to alleviate the pain and to cheer those who, without some such help, must pass the hottest time of the year and the time of the garden's greatest beauty in all the discomfort of the former and without any anticipation in the latter.

There are, as most of your readers are doubtless aware, several flower missions in London, the members of which go to the hospitals, &c., on visiting days and speak a few cheering words to each inmate, and whenever they can they leave a posy or a single bloom at each bed, and who can tell what that flower is to the poor sufferer? Now, if those exhibitors who read your Journal would consent to give their flowers, or some of them, to these missions, I feel sure the Directors would only be too glad to send someone to receive them at the close of the show.

If you approve of the plan will you please insert this in your next issue and request those exhibitors who are willing to give their flowers to send their names to you before the publication of the following number? and then, although it will be too late for the Alexandra Palace Show, some of the exhibitors at the Crystal Palace and other shows will have the pleasure of knowing that their flowers are affording happiness to others after having served their exhibition purposes.—A LOVER OF ROSE SHOWS.

ANNUALS AT REGENT'S PARK.

LAST year the great Holborn firm of seedsmen, Messrs. James Carter & Co., instituted an innovation in exhibiting by arranging the greatest display of annuals in pots ever brought together in this country. Although a first attempt on a scale of great magnitude, the Exhibition was so far successful and appreciated as to warrant the firm providing another display of the same nature this year. The season hitherto has been singularly dull, and by no means favourable for promoting the expansion of bright masses of flowers such as annuals are capable of producing, and it would not have been a matter of surprise had the Exhibition this year been comparatively dull, or, as some who are not prepossessed in favour of these floral simplicities would prefer to describe it, "weedy." The display, however, is neither dull nor weedy, but on the contrary it is singularly bright, cheerful, and satisfactory. The plants as regards their cultivation are decidedly better than last year, and they are also arranged more effectively.

When twenty-five thousand pots of annuals are grown and a floral picture of a month's duration has to be maintained it is a matter of necessity that the Exhibition must change in its character weekly, as fading plants must be replaced by others just expanding their flowers. On the opening day, for instance, we missed the charming miniature *Ionopsisidium aculea* that last year produced such a chaste display, yet this plant will probably be represented some time before the Exhibition closes.

The plants are arranged in the long corridor of the Royal

Botanic Society's Gardens, which structure they fill from end to end, forming a floriferous sloping bank of many colours, about a hundred yards in length and 8 or 9 feet in width. The more prominent colours are displayed in a series of large panels separated from each other by lines of contrasting colours and elegant groups of Grasses. Some of the panels are formed of brilliant masses of dwarf *Nasturtiums* (*Tropæolums*) comprising crimson, yellow, scarlet, and rose-coloured varieties; others are filled with *Schizanthuses*, than which few annuals are better worthy of cultivation in pots. The more noteworthy varieties are *S. oculatus albus*, very 'chaste'; *S. o. tigridioides*, richly feathered; and *S. o. atroviolaceus*, highly effective. The different varieties of *Centranthes* are represented also by bold yet elegant masses of rose and white; and extremely rich, perhaps the richest of all, are the intense violet groups of *Kaulfussia amelloides atroviolacea*. The variety *rosea* also makes a sparkling mass which finds many admirers. Perhaps, however, one of the most pleasing panels is of *Nolana paradoxa*; the large corulean blue *Convolvulus*-like flowers with white centres command much attention.

The taller plants consist chiefly of *Helichrysums* in variety, and white and yellow double and single *Chrysanthemums*. *Helenium Douglasii*, with brilliant, orange *Coreopsis*-like flowers, is extremely gay; and attractive are the *Gilias*, the lavender blue of *G. cespitosa major* and the pure white of *G. nivalis*. Dwarfier plants are composed of *Silene compacta* and *Leptosiphons*. Perfume is imparted by *Mignonette*, which, with Musk, forms the entire front row of the arrangement, backed by a long line of *Rhodanthes*.

On the opposite side of the promenade carpet bedding in miniature is represented; such plants as *Alternantheras*, *Netteras*, succulents, dwarf *Lobelias*, &c., being artistically associated in boxes 2 feet long, 1 foot wide, and 4 inches deep—a hint that those interested in window-sill decoration might well turn to account.

On the whole this Exhibition is an excellent one of its kind; it quite surpasses the display of last year, and can scarcely fail to popularise still more a charming and popular class of hardy flowers—annuals.

NOTES ON THE AMATEURS AND FLORISTS OF NORTH DURHAM AND NORTHUMBERLAND.

MR. JOHN WALKER, BELLE VUE, LOW FELL, GATESHEAD.

THERE are few flowers that gain more aspirants to master the secrets of their successful culture than Dahlias, nor perhaps is this to be wondered at when we consider their many hues of colour, their profusion of flowers, their graceful forms, and their long continuance in bloom in the autumn; indeed, the wonder is that in gardens of large pretensions they have of late become so much ignored. When most of our herbaceous flowers are on the wane, and our many styles of bedding-out are beginning to lose their attractions, we can look with pleasure on the bright and noble Dahlias. Dahlias have been cut quite fresh a few miles from Newcastle-on-Tyne on the 11th of November. That was in the year 1874, but once the thermometer falls much below the freezing point their doom is sealed. There are, perhaps, few more pleasing sights when the sun is setting on an autumnal eve than a *parterre* of Dahlias in full bloom. When the contrasts of colour and shades are viewed in the light of the setting sun each shade is vividly brought home to the eye as it were by Nature's own mirror.

But our present object is more to dilate on the properties of the Dahlia as a florist's flower, and to associate therewith the name of Mr. Walker. His career as a florist does not date very far back. He commenced but in 1871, and when it is stated that in that time he has taken a leading position as an exhibitor in the north, where so many Dahlias are grown, and in addition to that he travels three miles to his work, and is there by 6 A.M., and pursues his avocations in a heated forge as long as ten or twelve hours, some idea of the indomitable efforts he has employed to obtain a success may be estimated.

Mr. Walker's garden is not of large dimensions, and he is therefore compelled to grow his flowers annually on the same piece of ground. His culture is to dig over the ground one or two spits deep immediately after taking up the tubers in the autumn, and then to turn it over in February and again in April, at which time he adds cow manure not too much decomposed. Strong plants are prepared for planting out about the end of May. They are placed 4 feet apart, and the ground is mulched in July with 4 to 6 inches of horse droppings. As soon as the flowers show water is given copiously, and a little

guano is mixed with it. Insects are not permitted to exist on the plants; assiduous attention is given to tying and thinning the shoots; the blooms are shaded by encasing each flower in a muslin bag. This method he considers cheapest and best of the various modes of protection adopted.

Mr. Walker attributes his success mainly to the time and care bestowed upon the plants and flowers by having every little matter attended to when required; in fact, this may be said to be the secret of success in every department of gardening. Last year Mr. W. carried off nearly all the first prizes at both Alnwick and Bishop Auckland. Both Shows are generally the centres of a great display of florists' flowers. Appended is a list of Mr. Walker's favourite flowers.

Vice-President, orange buff; Flora Wyatt, orange; Alex. Roger, buff; Alex. Cramond, shaded maroon; Criterion, lilac; Baron Taunton, lilac; Mrs. Harris, white ground, lilac edge; Henry Walton, yellow ground, vermilion edge; James Cocker, purple; Jno. McPherson, purple; Ovid, purple; Willie Eckford, crimson; Delicata, salmon; Herbert Turner, white; Mrs.

Fig. 69.—*Erica mundula* (see page 466).

Stoncomb, pale yellow tinted with fawn; Prince Arthur, yellow; Buttercup, yellow; Mrs. Neville Keynes, yellow; Jno. Standish, bright red; Chris. Ridley, bright crimson; Hebe, light, edged with rosy purple; Memorial, rosy peach; Thos. Goodwin, dark; and Royal Queen, cream, purple edge.—B. C.

ROYAL HORTICULTURAL SOCIETY.

JUNE 18TH.

ROSE AND PELARGONIUM SHOW.

MOST popular of all hardy flowers are Roses, of that there can be no doubt; and most popular of all greenhouse flowers are Pelargoniums, of that there can be little doubt. A twin show, therefore, of those two flowers, assuming both to be well represented, could not fail to possess great attractions both to florists and general visitors. On the Society's posters, which were distributed generously throughout the metropolis, Roses were made the prominent feature, Pelargoniums being in smaller characters and secondary; but at the Show the reverse was the case. Pelargoniums there preponderated. The earliness of the date and low temperature that has lately prevailed prevented Roses being forthcoming in full force, yet for all that some splendid blooms were exhibited. In addition to the Roses and Pelargoniums the various nurserymen contributed collections of plants of great value and beauty, and these, with a strong and excellent contingent from Chiswick, formed one of the most attractive exhibitions of the year. The large marquee was filled without being crowded, the collections being disposed with much taste by Mr. Barron and his staff of assistants.

ROSES.—The warm and genial weather so generally experienced during the greater part of the month of June is considered by rosarians to be favourable to the development of large and bright Roses. The present month has hitherto been cold and cheerless; thunderstorms and fierce winds have generally prevailed, and have been almost continuous day after day. For a season like the present one the fixture for this Show was a little too early. These drawbacks no doubt prevented many exhibitors from entering, and consequently the quantity of Roses staged on this occasion was not so large as usual. Messrs. Paul & Son, Mr. Keynes, and Mr. Turner exhibited in fine form, as did several amateurs. The schedule was not a comprehensive one, but the prizes offered were remarkably good, and the amounts were such that had the season been favourable there would have been an immense competition.

In the class for forty-eight distinct, single trusses (nurserymen), Mr. J. Wyatt (for the executors of the late John Keynes, Castle Street Nursery, Salisbury), was awarded first honours for a remarkably fresh and even collection, consisting of *La France*, very good; *Maréchal Vaillant*, *Marquise de Castellane*, *Marie Baumann*, *Edward Morren*, *Madame Charles Wood*, *Princess Beatrice*, &c. Messrs. Paul & Son, The Old Nurseries, Cheshunt, were placed second with *Nardy Frères*, *Duchesse de Vallombrosa*, *Général Jacqueminot*, *La France*, *Cheshunt Hybrid*, *Madame Hippolyte Jamain*, *Mrs. Laxton*, *Centifolia Rosea*, *Monsieur G. Tournier*, *La Rosière*, *Abel Grand*, *Etienne Levet*, *Elie Morel*, *Mons. Fillion*, &c. Messrs. Curtis, Sanford, & Co., Devon Rosery, Torquay, third.

For twenty-four distinct, three trusses of each (nurserymen), Mr. J. Wyatt, Messrs. Paul & Son, and Mr. C. Turner were awarded the prizes in the order of their names. The first-prize collection comprised glorious *La France*, *Charles Lefebvre*, *Marquise de Gibot*, *Marie Baumann* (superb), *Etienne Levet*, *Souvenir d'un Ami*, &c. In the class for twenty-four distinct, single trusses (nurserymen), Messrs. Paul & Son were awarded the first prize for grand blooms of *Madame Prosper Langier*, *Marquise de Castellane*, *Miss Haasard*, *Horace Vernet*, *La France*, &c. The second prize fell to Mr. C. Turner, who had good examples of *François Michelin*, *La France*, *Madame Victor Verdier*, &c. Mr. G. Cooling, nurseryman, Bath, was third for a very good collection. In the corresponding class for amateurs the Judges awarded first honours to J. Hollingworth, Esq., Turkey Court, Maidstone; and the second to I. Jowitt, Esq., Old Weir, Hereford, for a very fresh and even collection. The Rev. J. B. M. Camm, Monkton Wyld, Charmouth, Dorset, received the third prize for a collection that consisted of several fine Tea Roses. For twelve distinct single trusses (nurserymen) Mr. Wyatt was again first, closely followed by Mr. Turner, who received the second prize, and Mr. Cooling the third. In the class for twelve distinct, three trusses of each (amateurs), the first prize was awarded to J. Hollingworth, Esq.; and the second to Mr. J. W. Moorman, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames, both showing very fine and even collections. For twelve distinct single trusses (amateurs) Mr. J. Ridout, gardener to J. B. Haywood, Esq., Reigate, was placed first; J. H. Pemberton, Esq., Havering-atte-Bower, Romford, second; and the Rev. J. B. M. Camm third, all showing well.

For twelve distinct, Tea or Noisette (open), John Hollingworth, Esq., received the first prize; Mr. Cooling second, and Messrs. Paul & Son third. For six of any one sort of Hybrid Perpetual (open), Mr. Wyatt won the first place with *La France*, Messrs. Paul & Son the second with the same variety, and J. B. Haywood, Esq., third with *Madame Victor Verdier*. The best six of any sort of Tea or Noisette (open), was *Maréchal Niel*, exhibited by Mr. Cooling; Mr. Jowitt winning second honours with *Cheshunt Hybrid*, and Messrs. Paul & Son third with the same variety.

For six distinct new Roses of 1876 and 1877 (open), Messrs. Paul & Son were a good first with *Madame Deveril*, Mons. Gabriel Tournier, Mrs. Laxton (which was perfection), Oxonian, Mrs. Baker, and Sultan of Zanzibar, which was very good; it is a very dark velvety variety, with a cup-shaped centre, and the outer petals reflexed. Messrs. Curtis, Sanford, & Co. were second. They exhibited Mons. Fillion, *Duchesse de Vallombrosa*, *Abel Carrière*, *Madame Sophie Trophet* in the way of Victor Verdier, Mons. G. Tournier, and a very large full Rose named *Madame W. Bull*.

Messrs. W. Paul & Son, The Nurseries, Waltham Cross, exhibited a collection of ten boxes of Roses, including one of Moss varieties, which was much admired. To this collection the Council awarded a silver Banksian medal. Mr. W. Rumsey, Joyning's Nursery, Waltham Cross, also exhibited a collection, and received the Society's bronze medal.

The prizes offered for Pelargoniums were liberal, and many of them were responded to by excellent collections. In a few of the classes, however, there was no competition, and in others some of the prizes were withheld.

SHOW PELARGONIUMS.—"Florists' class," by which is meant flowers of superior form in combination with regularity of colouring. Class I was for six plants, distinct, in pots not exceeding 8 inches in diameter. Mr. James, gardener to W. F. Watson, Esq., Redles, Isleworth, was in the foremost place with admirably

grown plants of Judith, Example, Magnificent, Superb, Isabella, and Scottish Chieftain, all of which fine varieties were sent out by Mr. Charles Turner. Second honours went to Mr. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, for plants far behind Mr. James's handsome specimens. For six plants, distinct, not in commerce, the renowned raiser E. B. Foster, Esq., Clewer Manor, Windsor, won the prize with the following:—Dauntless, rosy salmon lower petals, maroon top petals, smooth, round, and of great substance; Symmetry, a generally darker flower than the preceding; Invincible, very dark velvety maroon upper and bright salmon lower petals; Marmion, a flower of the same type as Dauntless; and Gladiator, rich glowing orange scarlet, maroon upper petals, and white centre.

FANCY PELARGONIUMS.—"Florists' class," six plants, distinct, in pots not exceeding 8 inches in diameter. The two exhibitors above named (Mr. James and Mr. Weir) were placed in the same positions in this class, Mr. James's plants being magnificent floral globes 4 feet in diameter, and Mr. Weir's much smaller. The first-prize varieties were Mrs. Hart, Mrs. Graham, Mrs. A. Wigan, Mirella, The Shah, and Princess Teck. For four plants, distinct, not in commerce, Mr. Turner, Slough, was without a rival, and won the chief prize with the charming varieties Joannette, Placida, Thurio, and Insulaire.

DECORATIVE PELARGONIUMS.—"Show" type, by which is meant varieties with fringed, spotted, or semi-double flowers, known as "market" or "regal" varieties. The chief class was for eighteen plants in pots not exceeding 6 inches in diameter. Messrs. J. & J. Hayes, nurserymen, Lower Edmonton, had the chief place with a charming collection, many of the colours, being exceedingly bright, and all pleasing. The varieties were Duchess of Bedford, Queen Victoria, Princess Helena, Prince of Orange, Digby Grand, Rosella, Prince of Wales, very bright; Bridal Bouquet, Magenta Queen, Prince of Pelargoniums, Dr. Masters, Alice, Duchess of Edinburgh, Baltic, Capt. Raikes, Le Patria, Triumphans, and Lord Derby. The value of such plants as these for decorative purposes cannot be over-estimated. For four plants, distinct, not in commerce, the same exhibitors won with Magenta Queen, purplish magenta, very floriferous; Prince of Orange, orange salmon, maroon blotch; Sultana, rosy crimson, white centre, glowing; and Le Grand, orange scarlet and maroon, very bright.

ZONAL PELARGONIUMS.—"Florists' class," or varieties with round, smooth, finely formed flowers. The chief class was for nine plants, distinct, in pots not exceeding 8 inches in diameter; and the premier prize was awarded to Mr. Catlin, gardener to Mrs. Lermite, sen., Finchley, with Heather Bell (Denny), Maud (Pearson), Titania (Denny), Miss Strachan (Pearson), Ebone (Denny), Remus (Postans), Ellen (Pearson), Laura (Pearson), and Agnes Emily (Catlin). The plants averaged 8 feet in diameter, and were very dwarf and floriferous. In the class for six plants not in commerce the celebrated raiser, Dr. Denny of Stoke Newington, won the prize with the following grand varieties of his own raising—Sunbeam and Manfred, scarlets; Oneida and Coreggio, rosy crimson; Madonna, pale rose suffused with salmon; and Dante, rosy lilac, white centre. For symmetry of flowers, smoothness and substance of petals, and clearness of colouring these splendid varieties are pre-eminent.

Zonal Pelargoniums, "Decorative class," or varieties with large trusses of showy flowers, such as Hybrid Nosegays.—In the class for nine plants, distinct, in pots not exceeding 8 inches in diameter Mr. Catlin won first honours with splendidly grown and flowered examples of Mrs. Turner, Col. Wright, Mrs. Huish, Rev. Atkinson, Charles Burrows, Rebecca, Lucy Bosworth, John Gibbons, and Thomas Adams. The varieties were all raised by the late Mr. Pearson, and two of them at least, Rebecca and Charles Burrows, have flowers as perfect in form as any in the florists' class. Mr. J. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, had the second prize in this class.

Four Zonals, distinct, not in commerce.—Mr. Catlin again won with Fanny Catlin, a grand rich salmon, fine flowers and truss; Edith Mary, pale salmon, splendid trusses; John Tullett, soft orange scarlet, fine trusses; and Nancy Lee, a very large salmon flower with white eye. All the varieties were raised by the exhibitor and are extremely fine.

For eighteen Zonals, irrespective of class, in which diversity and brilliancy of colour were considered primary points of excellence.—Mr. Catlin was here again triumphant with Rajah, Zuleika, Heather Bell, Dorothea, Titania, Clio, Faust, Gnome, Majestic, and Ophelia raised by Dr. Denny; and Lady Byron, Lady Eva Campbell, Lizzie Brooks, Rev. Atkinson, John Gibbons, and Mrs. Pearson, fine, raised by Mr. Pearson; and Stewart Durrant, raised by Mr. Catlin. The second prize was withheld, Mr. Weir being awarded third honours; and for twelve plants the first prize was withheld, second going to Mr. Brise, gardener to J. H. Lermite, Esq., Knights, Finchley.

VARIEGATED ZONALS.—In the class for eighteen plants arranged for effect of Gold and Silver Tricolors, and Bronze Bicolors, Mr. Meadmore, Romford, had the first prize with brightly coloured plants about a foot in diameter, but the foliage rather small. Mr. Burley, Brentwood, was awarded the second prize for a moderate collection.

DOUBLE PELARGONIUMS.—For eight plants of the "new dwarf type" in 8-inch pots Mr. Catlin was placed first with Madame Amelia Ballet, pure white; Noemie, rose; Jacobaea, scarlet; Louis Buchner (Sisley), salmon; Eugene Bandowin, rich pink; Sylphyde (Sisley), rose; Henri Buerrier, salmon; and Wonderful, scarlet. The plants averaged a foot in diameter and a little more in height, and were admirably grown and bloomed. Mr. Meadmore, nurseryman, Romford, had the second prize. For four plants of the same dwarf type not in commerce, Mr. J. R. Pearson, The Nurseries, Chilwell, Nottingham, won with unnamed seedlings of his own raising.

IVY-LEAVED PELARGONIUMS.—In the class for eight plants of hybrid or improved varieties Mr. George, Putney Heath, had the first prize with Nemesis, St. George, Gem, Angus, Duchess of Edinburgh, Progress, and Diadem, all of his own raising, and Konig Albert (Leibmann). For four plants of the same type not in commerce Mons. V. Lemoine, Nancy, France, won the prize with A. F. Barron, Mdle. Adrienne Barat, Madame Perle, and Madame Emilie Galle, all double, distinct, and good. A very elegant and valuable collection of Ivy-leaved Pelargoniums grown in the Society's gardens at Chiswick had many admirers. Their effect was singularly chaste yet cheerful, their colours being in effective contrast with the collection of Zonals from the same garden. There were no entries in the classes for Cape Pelargoniums.

SINGLE PLANTS.—For one large-flowered show Pelargonium, "Florists' class," not in commerce, Mr. C. Turner, Royal Nurseries, Slough, won the prize with Bertie, lower petals rosy salmon blotched with crimson, upper petals very dark maroon, of fine form and substance. For one double Pelargonium not in commerce the prize was won by Mr. Cannell; and for one hybrid or improved Ivy-leaved Pelargonium not in commerce Mons. Jean Sisley, Montplaisir, Lyons, France, won the prize with La France, a variety possessing great vigour and rosy cerise-coloured flowers; a fine hybrid and very distinct.

CUT BLOOMS.—For twenty-four large-flowered show Pelargoniums, three trusses of each, Mr. Turner had the post of honour with a collection of grand flowers set in their own foliage. The trusses were extremely imposing. For twenty-four Zonal Pelargoniums, three trusses of each, Mr. Cannell, the Nurseries, Swanley, won chief honours with a collection of great variety, brilliancy, and merit; Mr. Burley, Brentwood, being placed second. For twenty-four double Zonal Pelargoniums, three trusses of each, Mr. Cannell was without a rival, and arranged massive pyramids of wonderful richness and dissimilarity of colour.

MISCELLANEOUS COLLECTIONS.—Mr. Charles Turner did not compete in the Show Pelargonium classes, but gave the public a greater treat by exhibiting sixty plants in new varieties. The smoothness of the flowers and their great substance, and the clearness and intensity of the colours, place these varieties in the very foremost rank of greenhouse plants of superlative quality. A few extremely striking are Sappho, Fortitude, Criterion, Heraldry, Enchantress, Toby, Gipsy, Prince Rupert, Scottish Chieftain, Prince of Wales, Ruth, Archduke, Cicely, Mrs. A. Matthews, Isabella, Prince Leopold, Constance, Lord of the Isles, Illuminator, Viscount, and Evelyn. The colours may be found in Mr. Turner's catalogue. The varieties enumerated are the finest that have ever been staged at any exhibition. Mr. Turner associated with the Pelargoniums a few Palms and Liliiums, and was awarded a gold medal for the collection.

Messrs. James Veitch & Sons staged a charming group of tuberos Begonias, insectivorous plants, Ferns, new and rare ornamental-foliaged plants, and greenhouse Rhododendrons Taylorii and Maiden's Blush, and were awarded a gold medal; and a similar honour was won by Mr. B. S. Williams, who arranged a large and splendid collection, consisting of specimen ornamental-foliaged and flowering plants, Orchids, Amaryllises, Nepenthes, &c., and new highly coloured Dracenas. Mr. Bull also had a gold medal for a group of great value, elegance and richness being combined in a striking manner by splendid Orchids being associated with the charming Gauze Ferns. The spikes of Odontoglossums in this collection were extremely fine, as also were the gorgeous Cattleyas, and the effect of the flowers was enhanced by Cycads, Palms, and variegated Curculigos. A gold medal was awarded to Messrs. Rolleston & Sons for a very fine group of Ferns, ornamental-foliaged and flowering plants hardy and tender. One of the most striking plants in this collection was Iris Romulus, a rich violet colour, unequalled by any Orchid. Mr. Wills arranged a noble and artistic group composed of towering Palms and Tree Ferns with an undergrowth of Moss and flowers, Orchids and Gloxinias, and was granted a gold medal. A similar honour was granted to Messrs. Carter & Co., who arranged a very extensive, varied, and beautiful collection of decorative plants with a marginal boundary of carpet-bedding plants artistically arranged in boxes. A gold medal was further awarded to Messrs. Carter for an extensive and well-cultivated collection of annuals in pots, arranged in the entrance vestibule. They were much admired by the visitors. Messrs. John Laing & Co., Forest Hill, London, arranged a very fine collection of ornamental-foliaged plants, Roses, and bicolor Pelargoniums, and were awarded a silver Banksian medal. Very

striking amongst the Pelargoniums were John Jenner Weir, Exquisite, Mrs. Horniman, The Czar, Maréchal McMahon, and Impératrice Eugénie. Messrs. Hooper & Co., Covent Garden, contributed an extensive collection of decorative fine-foliaged plants, also tuberous Begonias, Achimenes, &c., and were awarded a bronze Banksian medal. Mr. H. Boller had a similar award for a collection of succulents, as also had Messrs. Cutbush & Son, Highgate, for Palms, ornamental-foliaged plants, New Holland plants, &c.—an excellent collection. Messrs. Osborn & Sons, Fulham, were awarded a silver Banksian medal for a fresh and attractive collection of ornamental-foliaged plants. A bronze Banksian medal was awarded to Mr. Burley, Brentwood, for baskets of Pelargoniums, including White Vesuvius, Dwarf White, Unique, and Mrs. McIntosh, a silver variegated with white flowers; all raised by Mr. Postans. Mr. Cannell was awarded a silver Banksian medal for a remarkable collection of cut blooms of Verbenas in forty-eight varieties. The richness and variety of colours and massive trusses represented in this collection arrested much attention and admiration. Messrs. F. & A. Smith, Dulwich, were granted a silver Banksian medal for a fine collection of decorative Pelargoniums. A silver Flora medal was awarded to Mr. R. Parker, Royal Nurseries, Tooting, for a splendid collection of cut flowers of Delphiniums, Paeonies, Irises, and other hardy flowers. Messrs. Barr & Sugden were awarded a silver Banksian medal for an extensive collection of cut flowers of Lilies, Irises, Pyrethrums, Lxias, Babianas, &c., very rich. A silver Banksian medal was awarded to Messrs. J. & J. Hayes, Edmonton, for a large collection of market plants, consisting of Pelargoniums, Fuchsias, Calceolarias, &c. A silver Flora medal was granted to Mr. H. Brown, Hendon, for an admirable collection of decorative Pelargoniums grown for market purposes, they were remarkably fine; and Mr. John Reeves, florist, Acton, was awarded a silver Banksian medal for a very bright and excellent collection of market plants. A bronze Banksian medal was awarded to Mr. Marcham, Springfield Nursery, Spring Grove, Isleworth, for a collection of striped Petunias of great merit. Their effect in the large mass was quite charming. Mr. Roberts, gardener to Baron Rothschild, Gunnersbury Park, exhibited a magnificent plant of *Odontoglossum vexillarium* with twelve spikes and seven and eight flowers on each. Mr. Roberts also exhibited fine plants and varieties of *O. Alexandra*, and was awarded a gold medal. A silver Banksian medal was awarded to Messrs. Downie & Laird, Royal Winter Gardens, Edinburgh, for a grand collection of Pansies, all seedlings of 1877 and 1878. For size, substance of petal, brilliancy of colours, and correct markings these flowers were remarkable, and they elicited a large share of admiration from the visitors who crowded round them.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. George Lee of Clevedon sent a dish of De Jonghe's Excellente Strawberry. This is a large cockscomb-shaped variety of a dark colour. It is said to be earlier than President, but not so good in flavour. Two dishes of "James Veitch" Strawberry were sent by General Fyche, Pyrgo Park, Romford (J. Lane, gardener). They were very finely grown and of a fine bright colour. Sir Thomas Edward Moss of Otterspool sent a fine dish of Strawberries which were supposed to be President, and one Melon not named. He also exhibited a dish of Tomatoes which were supposed to be Vick's Excelsior. Mr. George Monro of Potter's Bar sent six fruits of a new Melon called Lord Beaconsfield, the flavour of which was very good, but none of the fruit was perfectly ripe, and the Committee wished to see it again. R. Gosling, Esq., Hassobury, Bishop Stortford (C. Tyler, gardener), sent a new Melon called President, a fine green-flesh with a very thin rind and thick tender flesh, which promises to be a variety of superior excellence, but the fruit exhibited was not fully ripe. A dish of Loxford Hall Seedling Strawberry was sent from the garden of the Society. It is a cross between British Queen and La Constante. It is a good firm fruit with good flavour. Messrs. Rivers & Son of Sawbridgeworth sent a collection of five sorts of Orange, and also dishes of Hale's Early and Early Rivers Peach. Hale's Early was very superior in flavour, but Early Rivers was not so good, being rather bitter. A first-class certificate was awarded to Hale's Early. They also exhibited dishes of Belle de St. Tronc, Bigarreau Hâtif de Champagne, Bigarreau Jaboulais, and Bigarreau de Schrecken. Handsome trees of these varieties and nine varieties of Peaches in pots were also exhibited, to which a gold Knightian medal was awarded. Among the latter were several plants of Condor Peach, the fruit of which was of excellent flavour.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. First-class certificates were awarded to Messrs. T. Cripps & Son for *Clematis Viticella* Earl of Beaconsfield, a grand flower, rich Tyrian purple in colour, glossy and lustrous, and of great substance of petal; to Mr. Cannell for *Dactylis elegantissima aurea*, extremely chaste and elegant; to Messrs. Rollisson & Sons for *Erica obbata expollita*, a fine pure white variety with smooth glassy flowers; to Messrs. W. Paul & Son for Rose Countess of Roseberry, rosy salmon, glossy, of fine form, great substance, and sweet; to Mr. Noble for *Rhododendron Toccin*, bright rose, yellow blotch, fine truss; to Messrs. J. Laing & Co. for *Begonia Calypso*, rosy

salmon, double; to G. F. Wilson, Esq., for *Lilium Hansonii*, a grand plant with four spikes and upwards of forty beautiful massive flowers; and to Mr. Bull for *Dracæna Vivicans*. First-class certificates were also awarded to Mr. Charles Turner for the following Pelargoniums:—*Placida*, Jeanette, Bertie, Amethyst, and Insulaire; to Mr. Foster for Criterion, Marmion, Invincible, Symmetry, and Dauntless; to Dr. Denny for Manfred, Titania, and Sunbeam; and to Mr. Catlin for Fanny Catlin. Mr. Fisher, gardener to F. Williams, Esq., Woodlands, Balham, exhibited a plant of *Dendrobium Falconeri* containing 140 flowers, which was highly commended. Mr. Marcham's strain of striped Petunias had a similar mark of recognition, as also had Mr. Dean's double Canterbury Bells. Votes of thanks were awarded to Rev. A. Rawson, Bromley Common, for very fine blooms of *Cypripedium spectabile*; to Mr. Noble for Rose Queen of Bedders; and to Sir C. W. Trevelyan for Souvenir de la Malmaison Carnation. A first-class certificate was also granted to Messrs. E. & J. Perkins, Leamington, for *Potentilla Prince Arthur*.

NOTES AND GLEANINGS.

THE SUMMER hitherto has been one of the most dull and sunless that we have experienced. Nearly every day brings showers, and thunderstorms are prevalent. On Sunday the neighbourhood of London was visited by a heavy downpour which thoroughly saturated the ground in a few minutes, hailstones also being both large and numerous. The lowness of the temperature has retarded the growth of flowers and crops generally, one result of which is that the early Rose-show fixtures are fully too early. The low temperature has, however, probably been an advantage in another respect, for had the wet been accompanied by sultriness the Potato disease must have been serious, whereas at present it is only slight. Weeds are growing luxuriantly; slugs, where ducks and birds do not abound, are having a merry time of it, and gardeners are hardworked everywhere.

WE accidentally omitted to state in our report of the ROYAL BOTANIC SHOW of last week that the third prize in the amateurs' class for twelve Orchids fell to Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., Regent's Park; and an extra prize was awarded to Mr. Salter, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, both showing excellent collections; while in the amateurs' class for six plants Mr. Salter was placed first for an exquisite collection, exhibiting *Odontoglossum vexillarium* with over forty flowers, *O. Alexandra* very fine indeed, *Oncidium crispum grandiflorum* with ten spikes, *Dendrobium suavisimum*, *Epidendrum vitellinum*, and *Cattleya Mossiae*. Mr. Heims was placed second, and Mr. Bates, gardener to W. H. Punchard, Esq., Poulett Lodge, Twickenham, third. Mr. Child was awarded an extra prize, all exhibiting superb collections. Floricultural certificates were also awarded to the Rev. A. Matthews, Gumley, Leicestershire, for Pelargoniums Douglas, Osman, and Henry; to Mr. C. Turner for Pelargoniums Illuminator and Criterion; to Mr. J. Levesley, Isleworth, for Pelargonium Rose Levesley; to Messrs. J. Laing & Co. for Begonias Baron Leguay and Piercei vitellina; to Mr. R. Parker for Iris Darius; to Mr. William Bull for *Gloxinias* Duc de Cazes and Mdle. Angelina Martin.

THE prominent and successful manner in which *LILIAM AURATUM* is cultivated at Duncevan has been frequently adverted to, and the noble clumps of that fine Lily as naturalised in the *Rhododendron* beds have been figured in this Journal. Besides that form of culture Mr. McIntosh has a large and choice collection of *Liliums* cultivated in pots, and to which a new house is devoted. Some of the plants are now flowering, others are fading, and many are just expanding. Very attractive are the different varieties of *L. umbellatum*—namely, *excelsum*, *grandiflorum*, *croceum*, and *venustum*. Extremely beautiful are *L. Washingtonianum*, 6 feet high; *L. pardalinum*, very fine; and more richly spotted *L. californicum*, very waxy; *L. parum*, six spikes, a grand mass of golden bells; *L. colchicum*; and still more massive *L. Hansonii*; *L. ligulatum*, orange; and the rich and chaste *L. philadelphicum*. *L. Bloomerianum* ocellatum is much spotted and marbled; and *L. Humboldtii*, 8 feet high with sixteen finely spotted flowers, is very fine. *L. Kramerii* is represented by two distinct and beautiful varieties. But perhaps the most striking is *L. purpureum*, the flowers of which, however, are now fading. The four spikes produced an aggregate of ninety-three charming flowers. All the choice kinds including *L. neigherrense* are also growing in the grounds amongst the *Rhododendrons*, and in a bed on the lawn *L. giganteum* has made remarkable growth, the stem at a foot from the ground being 7½ inches in circumference.

— FEW flowers, perhaps, give better returns to the hybridiser than GLOXINIAs. Two years ago Mr. Fisher, gardener to T. Williams, Esq., Woodlands, Nightingale Lane, Balham, had two plants. These plants by having been intercrossed produced a great number of varieties, several of them being of great excellence, so much so that three of them have been awarded first-class certificates at the Royal Horticultural and Royal Botanic Societies. Several of the flowers are quite 3 inches in diameter and are of great substance. They include both drooping and erect-flowering varieties, and are in almost every variety of colour usually seen in those flowers. Such results obtained in such a short time and from such limited means are well worthy of being recorded, as affording encouragement to others desirous of increasing their stocks of these beautiful flowers. A simple mode of Orchid culture adopted by Mr. Fisher will be noticed on a future occasion. We can only now say that the finest example of the beautiful *Dendrobium Falconeri* is now flowering at Woodlands that has come under our notice.

— AMONGST the FREE-FLOWERING DECORATIVE PELARGONIUMS exhibited at South Kensington on Whit-Monday by the growers of plants for Covent Garden Market the following are specially meritorious:—Duchess of Edinburgh, white, delicate pink blotch on upper petals, very dwarf and floriferous; Mirror, soft scarlet; F. A. Dickson, scarlet and maroon; Commander, cerise; Mabel, velvety maroon and salmon; and Mermerus, improved smooth brick-red with a maroon blotch, free and fine. The above fine market varieties were exhibited by Mr. Brown, Brentwood Nurseries, Hendon. Amongst the richly coloured and floriferous varieties of the "regal" type exhibited by Mr. Reeves, Dr. Masters, Captain Raikes, and Beauty of Oxford commanded much attention. All the varieties named are very valuable for general decorative purposes both for rooms and conservatories.

— FOREST SEEDS FROM CALIFORNIA.—The systematic efforts at forest planting that several foreign Governments have entered upon are the source of a new trade from America. An export of forest tree seeds from California has been established amounting to \$10,000 per year. The principal purchases are made for Germany, Austria, England, and the colonies in Australia and New Zealand; at present the demand exceeds the supply. The seeds of the Oregon Pine, known also as the Yellow Fir, are most sought; the timber of that tree is as good as British Oak for shipbuilding, and has been found sound after eighteen years' use for this purpose. The South Sea colonies are planting the California Redwood Tree extensively.

— TO DESTROY WORMS ON LAWNS.—Dissolve 1 oz. of corrosive sublimate in a pint of hot water, adding two large handfuls of salt. When dissolved add nine gallons of cold water, then water the lawn with a common garden watering can through a rose. Nine gallons will go over 800 square yards, and should be applied immediately after rain, when the worms come up near to the surface of the ground. The application will make the worms appear on the surface, when they can be picked up by hand or swept up with a broom, taken away, and destroyed, care being taken not to put them in the way of ducks or poultry. The lawn should be well rolled immediately after the operation. Lawns done over three times, from October to March, will have a beneficial effect in keeping the worms quiet during the summer season, when lawn tennis, croquet, and bowling are enjoyable.—C. C. (in the *Journal of Forestry*.)

— MR. T. W. HELLIWELL, of Brighouse, Yorkshire, has recently patented and introduced a NEW SYSTEM OF GLAZING AND SLATING ROOFS, which is certainly superior to anything of the kind we have seen before. For a glazed roof no skylight frames or putty is required, and lead flashings, gutters, &c., are almost dispensed with. Rows or squares of glass and slates can be used alternately, thus saving the extra expense in wood or lead for forming roof lights. For railway stations, greenhouses, and other similar buildings it is especially adapted. No woodwork or other perishable material is exposed on the outside, and consequently outside painting is not needed. There are no crevices for moisture to leak through or insects to lodge in, any required amount of ventilation can be obtained without extra cost, and the whole structure can be taken in pieces and removed with the utmost facility. There is no possibility of breakage—except from ordinary accidents or carelessness—play for expansion being allowed. Old greenhouses or skylights can be re-glazed on this principle without

the expense of new bars, and its adoption will result in all cases in a considerable and permanent increase of light. It has already been used with satisfaction by several leading architects and horticulturists, and will, in our opinion, supersede any other similar system before the public.—(*Building News*.)

THE USE OF SULPHUR.

GREAT care should be taken by authors in the use of words to convey their meaning, for disastrous results may sometimes follow by using the wrong word, or not sufficiently explaining it so that it may be understood as it is intended.

In a much-valued work on Grape culture under glass now lying before me directions are given for the use of sulphur as a remedy for red spider and mildew, using these words: "There need be no fear of sulphur doing harm to the foliage so long as ignition does not take place, it may be used with confidence;" and in another place these words are used—"Without being ignited." Also in another work it is recommended to scatter sulphur upon the brick flues, but care must be taken not to let it ignite. Now I do not believe there is any harm intended in the use of the word "ignite," but I have met intelligent people who have an idea that to ignite means to blaze; that sulphur or any other substance is not ignited when it comes in contact with fire unless it blazes. I will cite a case to the point:—A wealthy lady of this town sent her gardener to me last autumn to see if I knew of a remedy that would destroy red spider in the hot graperies. I gave him one in which sulphur was to be used, but cautioned him to use great care and not let it come in contact with fire under any circumstances whatever. I saw no more of him for nearly two weeks, when he came back with a very long face and said that he had done as I had advised him, but it had not destroyed the largest of the red spiders. His employer had been reading in a work on Grape culture that sulphur could be used as I have quoted above; so in order to finish up the business she ordered him to burn a very small quantity to try it, but he must be very careful not to let it ignite! Now you see she had been misled into this error by the use of that baneful word "ignite," and the consequence was the gas or fumes from the burning sulphur destroyed every leaf in both the hot and cold graperies, for she ordered him to treat both houses to this dose. A little while after this happened I went to see those graperies, and I must say that it was about the sorriest sight I ever beheld; every leaf was as brown as a piece of leather. The Grapes in the hot graperies had ripened off in very good order (quite a large number of bunches still hanging on the Vines) before the igniting process had been applied, and were not much injured, but those in the cold graperies had just begun to colour, and of course were completely ruined. It was a scene of desolation I do not wish to see very soon again.

There is another case of a neighbour whom I met on the street one day last autumn, and wished I would go with him and tell him what was the matter with his graperies. As soon as I entered the house I thought it looked as if sulphur had been burnt, and asked him if it was not so. He said he had only burnt about as much as would lay on a five-cent piece. He had heard someone say that it was a good plan to burn it, and did not suppose it would do any harm. He wanted to get rid of those white thrips that were tormenting him so much. I told him that a small quantity of burning sulphur was enough to destroy everything that was green in a house of that size, and if he had used the remedy I gave him in the early part of the season he would have been all right.—(*American Gardeners' Monthly*.)

THE MYSTERIOUS DISAPPEARANCE OF FRUIT.

THE experience of "KENTISH FRUIT-GROWER" and others, as recorded in the *Journal*, corresponds exactly with what has occurred here. The trees bore a most abundant crop of blossom; but notwithstanding that for ten years so fine a spring has not been experienced here, fruit crops, excepting Strawberries and Currants, are almost nil. This result has not been the work of either spring frosts or insects, for the season has been remarkable here for the almost entire absence of both. It is no doubt another striking illustration of the importance of well-ripened wood in autumn. Last summer here was remarkable for its rainfall (67 inches for the year), and absence of sun, and its effects are not confined to the disappearance of the blossom without leaving us any fruit, but are manifested in canker and gumming of the trees to a re-

markable extent. More Roses, too, have died than in any spring for ten years, however severe the frosts have been. Rhododendrons, which grow here so well, and I may say by scores of acres, are very thin of flowers, while owing to the genial May the leafage in the forests is remarkable for its health and extent.—D. THOMSON, *Drumlanrig*.

CAPE HEATHS.—No. 6.

JUNE.

CONTINUE to water carefully and regulate the growing plants. In the case of young plants the shoots must be judiciously stopped—that is, pinched out at the points in order to produce a greater quantity of growths, and thus lay the foundation of a robust and bushy specimen. Older specimens

Fig. 70.—*Erica speciosa*.

of the hardwooded kinds that are past blooming should have all the flowers pulled off, and most of the leading shoots stopped; whilst those of the softwooded section as they pass out of flower should be cut back hard, or they will grow tall and lanky and become bare of foliage at the bottom. The following kinds are now in full beauty, and it is very gratifying to see the fancy again coming round to these grand plants; indeed, the manner in which they have been brought out at the recent exhibitions would lead us to hope they, like the Auricula, will again be popular.

E. vestita incarnata.—An erect-growing plant with many simple branches. Leaves numerous, densely set, arranged in sixes or eights, linear, erect, slender, and deep green. Flowers arranged in whorls a little below the tops of the main branches; in shape cylindrical, upwards of an inch long; base of the tube white, suffused with deep rose towards the mouth.

E. vestita fulgida.—Similar in general habit to the preceding, but more robust and with stronger leaves, which are also more laxly set. Branches simple. Leaves in sixes, linear, obtuse,

deep green. Flowers in dense whorls, an inch long and deep reddish crimson in colour.

E. mundula (fig. 69).—An elegant neat-growing plant, dwarf and much branched. Branches slender. Leaves in fours, subulate, lax, and pale green. Flowers also in fours, erect and terminal, tubular, with a contracted mouth and spreading limb. Limb on the upper side bright red in the centre, bordered with white, beneath wholly bright red.

E. mirabilis.—Leaves arranged in fours, linear, obtuse, smooth, and dark green. Flowers terminal, in fours, sessile, much swollen at the base, contracted at the mouth and having a large spreading limb, the segments of which are somewhat heart-shaped. Colour white, suffused with flesh or rose.

E. speciosa (fig. 70).—A fine bold-growing plant, and although it must be acknowledged a rather shy bloomer, it nevertheless deserves space in every collection. Leaves arranged in threes, linear, obtuse, slightly hairy, and deep green. Flowers in threes, sometimes in fours, terminal on the small branches, tubular, upwards of an inch long, pendent upon coloured footstalks, shining and viscid, deep rich red in colour, tipped with green.

E. sulphurea.—This plant belongs to the softwooded section, and is very useful as a table plant independent of its attractions in the greenhouse. It is an erect-growing plant with numerous scattered branches. Leaves arranged in fours, linear, obtuse, hirsute, and dark green. Flowers terminal on the lateral branches and forming long spikes, in shape cylindrical, slightly recurved and hairy, smallest at the base, increasing upwards to the mouth; bright sulphur yellow in colour.

E. Irbyana (fig. 71).—A fine species, producing long slender branches. Leaves arranged in threes, subulate, mucronate, somewhat triangular, flat above and keeled below, deep green. Flowers nodding; footstalks red, produced in terminal umbels of six to ten, much swollen at the base, narrow at the mouth with a spreading limb. Colour pure white, tinged with rose or flesh towards the base, and very glutinous.

E. tricolor profusa.—A fine hybrid, originating in the nurseries of Messrs. Rollisson & Sons, Tooting, a firm that have done so much in raising new hybrid Heaths. It is of good compact habit and free-growing. Leaves mostly in fours, linear acuminate, and dark green. Flowers nearly terminal, produced in very large whorls, tubular, with a much-swollen base; colour rich rosy carmine, changing to pale rose; limb white, with a circle of bright green round the neck.

E. opulenta.—This belongs to the tricolor section, and is a very fine variety either for home decoration or exhibition purposes. Leaves dense, usually in sixes, obtuse, and dark green. Flowers large, tubular, swollen at the base; wholly a rich crimson lake; limb flat, tips white. It is another of the Messrs. Rollisson's grand hybrids.

E. campanulata.—A slender-growing but elegant species. Branches slender, leaves mostly in threes, subulate, smooth, light green. Flowers numerous, bell-shaped, drooping, bright yellow. Its free-flowering habit and distinct character should render this a favourite with every Heath-grower.

E. Hartnellii.—A fine old kind of great beauty now in full flower. Leaves dense, mostly in sixes, hairy, dark green. Flowers nearly terminal in large whorls, tubular in shape, pale red saving the neck, where it is encircled with a band of green.

FRUIT PROSPECTS.

WE had a splendid show of bloom on Apple, Plum, and Pear trees, and an entire absence of frost at that critical period. Plenty of fruit was set; but owing to the very wet and cold May, and apparently June also, the fruit has gone off very much. Our rainfall for May was over 4 inches, which, with scarcely any sun, has rendered the soil very cold. Apples and Pears are gone off more than Plums; they first turned yellow by degrees and then fell off, not gradual turning as we sometimes see, but the whole crop in some cases. Although the bloom looked well I do not believe it was ever very strong, for it could stand no rain, and I believe the wood of everything more or less was in a very unmaturing condition, owing to the absence of the solar influence last year. I do not think we shall get a good fruit year until we see the trees clothed with a better foliage than they have had for some

time past. Many trees this year, and young trees too, have many dead pieces in them, and the foliage looks yellow and puckered. Now, this is not the effect of frost this year, and no doubt we have often blamed frost undeservedly. Currants are a very good crop. Gooseberries thin. Strawberries a very heavy bloom, but much of it has turned black, and they evidently want sun. Raspberries are blooming very freely.

Of indoor crops, the crop of Peaches and Nectarines now ripening is very good; the later houses not so good, the wood not being so well ripened. The first Grapes are ripe and are the best crop, every successive house being worse in that respect—the first being a very good crop, the last a very middling one. It was very difficult to get late wood ripe last year. The Potatoes look very well here at present, but I am afraid this wet weather is not at all favourable to them as regards disease.—JOHN PLATT, *Gardens, Hillington, Norfolk.*

ROSE SHOW PROSPECTS.

Now, on June 10th, it is not impossible to make a forecast of the shows of the period. Now is the time of expectation. Many and many an intending Rose-shower walks now day by day through his Briars, or Manettis, or maiden blooms, or all three, and more if he is a leviathan, taking stock of their possibilities and disbudding as he passes them in review with just severity. Disbudding is a practice that deserves discussion. There is no doubt it makes the bloom larger, but at the cost, as I judge, of the character of the variety. I do it, like everyone else, but I have sometimes found a bloom quite as good which I had left in the bosom of his family. In some cases the attendant bud-lets keep quite small and appear to take very little of the sap away. I should like to see a class for which disbudding was interdicted. Certainly Noisettes and Roses of a cluster character lose through the practice a certain portion of their beauty. But this is a digression. The intelligent individual I contemplate does more than disbud; no doubt he has been mulching, according to the most valuable suggestions of "THE HEREFORDSHIRE INCUMBENT" in his article in our Journal of May 30th. "Agitate! agitate! agitate!" was the old Corn Law Reform recipe. "Mulch! mulch! mulch!" is, I believe, Mr. George Paul's advice as a preparation for the heats of summer. I have never before put on the summer coating of manure so early, but am now thankful for the advice to do it, and rejoicing greatly in the way in which the late rains have made use of it.

Judging from the state of things in Mid-Surrey I should this year expect there to be very first-rate Rose shows. I incline to think Roses so far have seldom had so propitious a season, at least on light soils, for I have little experience of the stiff clays. There hardly ever were such crops of grass as I see this year—heavy mowings, as a veteran of the scythe has just remarked to me; and where the Rose bushes have pushed three or four large buds clear of caterpillars, and with clean and well-washed foliage, I cannot but anticipate, when the warm weather at last comes, an excellent tribute being laid at the feet of our Lady Flora. In these parts, however, there are a great many faulty blooms: they come cracked, and of a type which hardly ever opens perfectly. Where I know not exactly, but about the middle of May a frost came which has marked with blotches some of the faster-growing foliage, and which appears also to have damaged some blossoms. A far more serious thing here is a very general want of Apples. After a fair amount of blossom the quantity of the fruit hereabouts appearing is most discouraging. There is always something, and there is always something to make up for it; and a very large balance—(who does not thankfully admit it?)—there always is on the side of "things richly given to us to enjoy."—A. C.

LARGE CYATHEA MEDULLARIS—DAHLIA CULTURE.

WHEN staying during the Manchester Show with my friend Mr. Tinsley, at Grappenhall Lodge, he was kind enough to drive me over to Tatton Park, the seat of Lord Egerton of Tatton, near Knutsford. There was not much very noteworthy about the place save the park itself, which is very extensive but flat. There is, however, in the fernery what I imagine to be one of the finest specimens of *Cyathea medullaris* in England, at any rate in any private collection. Its stem is 18 feet high, and the fronds are 16 feet long, so that it has a very grand appearance, the fronds being in perfect health.

I noticed also in the garden a way of treating bedding Dahlias I had not seen before. The top is pinched out, and the plants are then pegged down, and thus are kept very dwarf and show a good head of bloom. There was also in the kitchen garden one of the most extraordinary visitations of American blight I have ever seen—a whole row of dwarf Apples completely smothered with it; and as nothing seems to be done to overcome it, not only must the trees ultimately perish, but the whole garden must be poisoned with it.

I saw in Mr. Tinsley's garden, who is by-the-by one of the most energetic of the local Secretaries of our National Rose Society, a mode of treatment of Clematis Jackmanii which I had not seen before, and which is well deserving of imitation. A border was made of about the same width as the Ivy borders one sees so much of in Paris, and the plants being kept within

Fig. 71.—*Erica Irbyana* (see page 466).

bounds it looked very neat, and gave, moreover, a succession of bloom all through the summer months. I have seen it used for a bed before, but never as a border.—D., *Deal.*

BATH AND WEST OF ENGLAND SOCIETY AT OXFORD—SUPPLEMENTARY NOTE.

AMONG the contributions to the Exhibition not staged till the second day a collection of Orchids, some thirty in number, from W. E. Brymer, Esq., Ilslington House, Dorchester, are worthy of especial notice for the healthy condition, abundance of really fine flowers, and unblemished state in which they were shown, for they were as fresh-looking as if they had only been brought a distance of a few yards from the Orchid house to the tent, and yet they were sent off from Ilslington to Oxford, a journey of some 120 miles, early on Whit-Monday, and were not received at the tent till the evening of that day. We saw them unpacked, and noticed that each flower spike was fastened securely to a single stake, and effectually screened from contact with cold currents of air by an envelope of wadding and paper kept well away from the flowers by four stakes, around which it was wrapped and made fast above and below the flowers—a simple process thoroughly well done. In a good room or well-constructed tent no harm can

happen to Orchids under ordinary circumstances at this season of the year, and we have no doubt the forlorn bruised condition which they so frequently present when taken back from an exhibition is more often owing to unskilful packing than to the atmosphere of the place in which they are shown. After the Orchids were staged there were frequent storms of wind accompanied by heavy rain; but so admirably was the tent constructed that not a drop of moisture or any sharp current of air came near them, immunity from the latter evil being secured by making a couple of curved recesses in the stage at the centre and well away from the doors. Some of Mr. Brymer's Orchids were very fine, notably *Masdevallia Harryana*, which had numerous rich crimson flowers; *M. Veitchiana*, with about a dozen brilliant orange-scarlet flowers streaked and tinged so exquisitely with purple as to baffle description; *Epidendrum vitellinum*, with five spikes of its deep orange-scarlet flowers; *Odontoglossum Pescatorei*, with a grand spike; *Oncidium hastatum*, also very fine; *Epidendrum prismatocarpum*, a grand plant with eight spikes; *Brassia maculata* and *Cattleya Mossiae*, both very beautiful. The entire collection reflected much credit upon Mr. Catt the gardener.

On the second day some stands of Roses contributed by J. H. Arkwright, Esq., Hampton Court, Leominster, Mr. Mayo, and Mr. Prince, added materially to the beauty of the Show. A specimen plant of *Mignonette* brought by Mr. Boscawen from Lamorran is also worthy of mention; for although the only example of our old favourite there it was quite worthy to stand alone, being a large, handsome, well-grown plant, all the more remarkable from the fact of its being raised from a cutting.

Reference has already been made to the collection of native wild flowers exhibited by the Rev. W. Tuckwell, but it was worthy of more than a passing notice. It consisted of some seventy species and varieties, not shown in large hideous bundles as is often done, but with just a small spray or two of each sufficient to convey a clear idea of foliage and flower; each kind inserted in a little tube fastened in rows upon a neat rack, with a card beside it so clear and to the point that we print an example. Many of these wild flowers were so beautiful as to merit a place in perennial clumps as well as being turned to account to make gay the margins of woodland walks. Of such we selected a Dropwort (*Spiræa filipendula*) with elegant Fern-like foliage, and pretty pale lemon-coloured flowers tinged with pink, and with round clustering flower buds of a deep pink with slight indications of the interior lemon colour; *Alchemilla vulgaris* or Lady's Mantle, worthy of a place for its handsome foliage; the Pheasant's-eye (*Adonis vernalis*), with elegant finely divided foliage and pretty little deep crimson flowers; *Hyoscyamus niger*, the curiously veined-flowered Henbane; *Campanula glomerata*, the Clustered Campanula, of a lively pleasing purple shade of colour; Jacob's Ladder, the *Polemonium ceruleum* of our flower borders, alike ornamental in leaf and blossom; the large Hawkweed (*Hieracium aurantiacum*), bearing numerous compact clusters of deep orange flowers; *Centranthus ruber*, the Red Valerian, so pretty at this season of the year with its clustering spikes of bright rosy pink flowers; *Viburnum Opulus*, the wild Guelder Rose, worthy of a place in every shrubbery not only for its white flowers now but for its charming clusters of polished berries, some being bright crimson in colour and others almost black; *Mimulus luteus*, with pretty yellow flowers—it answers well in a poor soil, and will flourish wonderfully in a shallow stream. We have a large patch of it planted originally on the bank of such a stream, and it has crept down into the water and along the channel for some yards, throwing up shoots from 1 to 2 feet in height. *Salvia pratensis*, or Meadow Clary, a pretty flower with tall spikes of light purple; *Epilobium hirsutum*, the Great Willow-herb, a striking plant with tall spikes of large deep pink flowers; *Astrantia major*, with curious pale pink flowers; and that other pink flower of cottage gardens, the Thrift (*Armeria vulgaris*). The Sweet Flag (*Iris Pseud-acorus*), well known and valued for its beauty by the side of water; *Lychnis vespertina*, better known perhaps as White Campion, a handsome bold white flower; the Sun Cistus (*Helianthemum vulgare*), deep yellow, and of which we now have so many charming varieties. And of the *Geraniums*, sanguineum, or Blood-red Cranesbill, valuable for its foliage as well as for its deep pink flowers; *G. sylvaticum*, having deep rosy purple flowers of good form; *G. pratense*, with white flowers and handsome foliage; *G. lucidum*, a charming miniature pink variety.

ARRANGING A CEMETERY.

THE laying-out and general treatment should be as for a gentleman's ground or park; still the cemetery may and must have a character of its own, not forced, or artificial, or severe, but natural and graceful. This character can be expressed in

no way so well as by judicious planting. The selection of trees for a rural cemetery calls for the exercise of taste on the part of those to whom the work is committed. The evergreens, especially those of a slender form like the *Arbor-Vitæ* and *Junipers* and the English Yew, are particularly appropriate, but even these should not be used so freely as to give a gloomy appearance to the landscape. The weeping trees are always acceptable. In addition to these two classes any of our native or foreign ornamental trees may be introduced. Avoid too profuse planting. Every tree should have room for its full development, and no pruning knife should be allowed to touch an ornamental tree. Its beauty consists in the form given it by the Creator, a beauty which all can admire, which we can also mar but cannot mend. Trees are to ornament the grounds, and too much planting produces the same unpleasant feeling that always results from profuse ornamentation, whether upon the person, the house, or the grounds.

The flowering shrubs—the *Lilacs*, the *Syringas*, and *Weigelas*—need not be neglected, but should not be scattered over the grounds promiscuously, as they give it a broken and untidy appearance. Plant them in groups in appropriate places, and so close together that the group and not the single plant is daggered upon the eye. A beautiful group may be formed of the most ordinary shrubs, that, if planted singly, would rather disfigure than beautify the grounds.

When such cemeteries are common, and our friends ask us what they had better plant in their little burial lots, the answer will be easy—a few groups of simple sweet flowers, such as the *Lily of the Valley*, the *Snowdrop*, the *Forget-me-not*, the *Daisy*, the *Violet*, with clumps of a few *Roses*, white *Lilies*, and the *Dicentra*, *Anemone japonica alba*, and plants of a similar character that will look well and do well. A few *Crocuses* and *Snowdrops* planted in the grass will make a very pretty appearance in the early spring.—(*Vick's Magazine*.)

NOTES ON VILLA AND SUBURBAN GARDENING.

WE never remember a season which has brought us the same amount of work as the present one has, and every effort has had to be made to keep pace with the necessary requirements of the garden. Seedling weeds have grown very quickly, and have had to be either pulled up with the hand or first cut down with a hoe and promptly raked off the ground, or they would have quickly taken root again and our labour would have been thrown away. Lawns have required more than usual attention to keep them short and in good trim, and the verges have required extra clipping to impart to them anything like a finished condition. But, on the other hand, we have had much to be thankful for; the frequent heavy rains have been highly beneficial in maintaining a beautiful green surface to our lawns, and the trees and shrubs have made unusually luxuriant foliage, which at the present time is remarkably beautiful, while to all late-planted shrubs and newly laid out villa gardens there has been a great saving of labour, the turf having taken well hold in its new situation, and the shrubs in many cases have rooted so well that a season's growth will be gained. Notwithstanding such genial and showery weather conducive to healthy growth and good foliage, Roses on walls are in many instances much infested with aphides. Hard washings from a garden engine must be applied to them as long as there are any fly to be seen, or it will be useless to expect a good second growth and a further supply of flowers as the season advances. Standard *Roses* and others growing in beds or borders also require timely attention to eradicate these insects. Many *Roses* are now showing well-formed flower buds, and such that well repay the cultivator for the labour bestowed on them in keeping them clean. Regulate the growths of *Clematises* on walls, or they soon become a tangled mass.

In the flower garden the bedding-out of the summer plants ought now to be finally completed, but where spring bedding is carried out extensively it frequently happens that some of the spring flowers are in their full beauty in early June. *Silene pendula*, for instance, is one of those backward spring bedders, but how exquisitely beautiful is a large bed of the pink variety when well filled and fully in bloom! We have had beds of this now gay for some weeks—so gay that no summer bedding plant can approach it; but these are now fast fading, and *Coleus* and such-like tender plants will be planted in their places. *Silene pendula compacta* we strongly recommend either for edgings of large beds or for the filling of smaller beds, and those who do not object to bedding-out late should raise a supply of these gay *Silenes*. Instructions for doing so will be found on page 442. Embrace every favourable opportunity for running the hoe through the beds that have now been recently planted. This is highly beneficial, both by killing seedling weeds and loosening the soil around the plants and admitting the air to the roots. At present around the neighbourhood of London artificial watering

is not necessary, copious rains having fallen from the clouds. Peg down and regulate the growths of Petunias, Verbenas, Heliotropes, and such-like trailing plants. Box edgings to flower gardens not already clipped should be cut at once.

In the kitchen garden there is now much work to be done, for neglect now of only a week may be the loss of a crop and entail much vexation and disappointment at the end of the season. If Parsnips and Onions are not finally thinned not a day must be lost in completing the work. Thin Parsnips to a foot apart and Onions to 9 inches if large-sized produce is required, but a distance of 6 inches will enable some fair-sized bulbs being produced. Prick the thinnings of Onions out in a spare piece of ground, and these will afford a supply for pickling purposes. Carrots must also be thinned, but sometimes it is well to thin sparingly and draw the others as they are wanted for cooking, but by no means allow them to become matted in the rows. Beetroot is of sufficient height to be thinned, and if there are blanks in the rows transplant some of the young plants, which will by the end of the season make very fair-sized roots; large Beetroots are not generally wished for.

As soon as all the early Peas have been gathered pull up the rows and crop the ground again, for in very few gardens is there any chance allowed for the ground to remain long unoccupied. Celery is a good crop to follow Peas. Prepare the trenches by digging them out 18 inches wide and the same in depth, placing several inches of well-decayed manure in the bottom, and as soon as the plants are strong enough carefully lift them with a trowel and plant them in these prepared trenches. A sharp look-out for slugs must be made on the rows of Scarlet Runners and Dwarf Kidney Beans or they will very soon devour the lot. A row of fresh-slacked lime placed around the plants will sometimes preserve them, but trapping and catching the slugs is a safe cure. Make further sowings if sufficient plants are not growing. Earth-up the latest crops of Potatoes before they become too far advanced, and thin the second and third sowings of Turnips before they have become too crowded. Make further small sowings of Lettuce, Endive, Radishes, Carrots, Parsley, Chervil, and small salads. A very good plan with Lettuce is at this season of the year to sow in drills a foot apart where the plants can be left to attain their full size, and plant the subsequent thinnings out for successional supplies. To obtain good crisp Lettuce a rich border and a plentiful supply of water is requisite. The Paris White Cos is one of the best varieties for producing a supply throughout the summer. Cauliflowers are now fast turning in. Make a further sowing of Walcheren at once for a late autumn supply. Plant out Brussels Sprouts; the main crop of this useful esculent can scarcely be planted out too early.

Chrysanthemums should no longer be left in their small pots, but must be placed in their blooming pots at once. For producing large flowers we place one plant in an 8 or 9-inch pot, but specimen plants should be potted in 12-inch pots. Stake the plants as soon as they are potted to prevent the wind snapping the tops off. We pot firmly, using good loam mixed with a small portion of decayed manure.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THERE must be no delay in thinning the root crops, for when this is neglected they become drawn and are more susceptible of injury from drought. It is desirable to apply a dressing of soot immediately after thinning, which will tend to keep off insects and be beneficial to the plants. Guano applied at the rate of 2 lbs. per rod (80½ square yards) is an excellent dressing. Endive should now be sown for the first main crop in drills 15 inches apart, and the plants thinned to 12 to 15 inches. This is better than transplanting, which often causes the plants to run, and makes much needless work for the watering pot. Round-leaved Batavian and Green-curbed are the best sorts. The London or Rosette Colewort is not so much grown as it deserves. Its productiveness, adaptability for withstanding severe frost, and requiring little room render it desirable. Sow the seed now, and when the plants are fit to transplant do so, allowing 15 inches every way. Ground that has been occupied with Potatoes, Peas, or autumn-sown Onions will be available for this crop. Finish the cutting of Asparagus, for it is necessary that the plants should have time to make and mature a good growth, upon which depends the development of the buds for the ensuing season's supply. In exposed situations secure the top from being broken off at the ground by stakes, and run string from one to the other. Keep Tomatoes well supplied with water and well mulched with short manure, remove all side shoots when the required number of fruiting shoots is obtained, stop one joint beyond the truss when the flowers open, but if the plants show fruit plentifully little stopping is required.

FRUIT HOUSES.

Pines.—Fire heat will not be necessary now for successional stock, except in particularly cold localities, for sufficient heat will be maintained to secure the steady growth of the plants, or a temperature of 65° at night, if attention be given to ventilation in the day time, which is very necessary to secure sturdy growth.

Admit air at 75° if the morning be bright, gradually increase it until the temperature reaches 85°, when full ventilation will be required. Reduce the ventilation gradually, keeping it up to 80° as long as possible, at which close, affording the plants a light sprinkling overhead when the weather is bright. It will still be necessary to afford the needful warmth to the roots of the plants—viz., 80° to 90°, and to accelerate plants in an advanced fruiting state in houses, the bottom heat of which is furnished by hot-water pipes. The earliest fruiting plants will now or soon furnish a number of suckers, which should be taken off and started at once. These will form a supplementary batch to those started in March. They must be watered at once if the soil is dry, and shade afforded from bright sun until they are well rooted.

Melons.—Outdoor fruit not being equal to expectation make good the deficiency as far as possible by making every empty house, pit, or frame available for Melons. Some consider Melons are worth little after the hot days of summer, but they are often good when the days are bright in September and October. Plants that were raised some time ago as advised will have been put out, or should be at once; they will set freely in the dog days and afford very acceptable fruit in late August and September. A last sowing should be made for growing in dung-heated pits and frames. It is advisable to make up the beds at once, or at the same time as the seed is sown, which should be in 4-inch pots about half filled with soil, placing in a frame or house at work. One or two seeds may be put in each pot, and soil placed around the stem as the plants advance, but not higher than half an inch of the seed leaves. When the fruiting bed is ready turn the plants out of the pots, place one in the centre of each light, planting to within half an inch of the seed leaves, with the soil inclining from the stem, give a good watering, and shade from bright sun. Pinch out the point of the leader at the second rough leaf, which will induce side shoots; reduce these to four, take two to the front and two to the back of the frame or pit, rubbing off the laterals to within 9 inches of the stem all around, and every other lateral upon the primary shoots, stopping those at 6 inches from the sides of the frames. The plants will be showing and setting fruit in plenty early in August, and they will ripen in late September. All the stopping and disbudding must be done whilst the growths are small, for large reductions of growth only tend to grossness in the parts retained, and are unfavourable to the setting of the crop. Little Heath is one of the best for late work, and has the advantage of keeping well; Colston Bassett is more highly flavoured than many late in the season. The grower who has well-heated light houses will have no difficulty in maintaining a supply of fairly flavoured fruit through October and November from sowings up to the third or fourth week in July. Husband sun heat by early closing in pits and frames; only a slight shade in the middle of the day in the hottest weather will be needed, and not that if the soil be firm and stiff and the plants duly supplied with water.

FLOWER GARDEN.

Push on the propagation of spring-flowering plants. Primroses ought to have been attended to; if not, divide them into as many parts as there are crowns with roots. Daisies should have a shaded position in the reserve garden, or an east and west border, duly shading and watering until established. Arabis, Aubrietias, and Myosotis (Forget-me-nots), do best upon a north border; the cuttings should have a fair amount of stem, and be kept moist and shaded if the sun reach them. Viola and Pansy cuttings insert in a shady border, selecting those springing from the roots; shade from bright sun and keep moist. Golden Thyme strikes freely under handlights on a north border. Stachys lanata is useful for winter bedding, and should be divided and planted in a shady place. Gentiana acaulis is one of the most beautiful plants for spring blooming. The plants should be divided and grown in a slightly shaded situation and kept moist. Sow now Wallflowers for blooming next spring, and any other biennial or perennial plants, also Stocks of the Brompton, Giant, and Queen varieties for next season's display.

Favoured by the late rains bedding plants have progressed favourably and will soon cover the beds. Remove all blooms as they show, which will cause the plants to cover the ground much sooner than if they were allowed to flower at this early stage. Attend to Verbenas and other plants that require pegging. If the soil be light and shallow mulch with old Mushroom-bed manure or other spent material not too rich, as that would tend to growth instead of flowers. Mulching is of great benefit in light soils in a dry season, the plants are then almost independent of the watering pot. Cocoa-nut fibre refuse is a good mulching material and has a very neat appearance. Frequent mowings are necessary to keep lawns in order. This season they could not be kept at all down without a run over once a week: the hard and close cutting tells upon the grass in time, and should be relaxed whenever a dry period occurs, setting the cutters a little higher so as not to cut too close. Bents which usually escape the machine and are a great disfigurement, are readily cut with the scythe. Walks should be frequently rolled to keep them smooth and firm. Salt now given will destroy moss and small weeds, but it should be applied in settled weather, as heavy rain will prevent its destroying the weeds. Care should be taken not to sow it too

close to the grass or Box, as it will spread and injure those or other live edgings. Box is easily killed, and in such cases it is best to avoid the salt.

Rhododendrons and other American plants do not thrive well in some soils, especially those loose and dry. A dressing of decayed cow dung or leaf soil will be found beneficial, and failing these a mulch of cocoa-nut fibre refuse or grass mowings will conduce to a moister soil and enrich it, which will be seen in the increased vigour of the plants. Any shrubs or trees not in a thriving state may have a mulch of similar material, it being a great mistake to remove the leaves and not return anything in their place.

PLANT HOUSES.

Stove.—Gardenias out of flower should be cut back, but young plants are preferable. They are so liable to mealy bug and scale that every opportunity should be taken to keep the pests in check. A thorough cleansing may be given at the time of cutting back, as the plants will then endure an insecticide at a strength that at other times is often injurious. Lay the plants on their sides and syringe with paraffin, a wineglassful to four gallons of water, keeping thoroughly mixed by squirting alternately into the liquid and over the plants, or 6 ozs. of soft soap to a gallon of water, adding a wineglassful of spirits of turpentine to every three gallons; apply as in the case of the paraffin, but keep both from the roots of the plants. The paraffin is the most effectual remedy and is not so expensive. When the plants have shoots about an inch long shift them into pots about 2 inches larger, reduce the balls about half, preserving the roots, and work the soil well in. *Gardenia florida* and *G. Fortunei* have the largest flowers, *G. intermedia* is the most useful for cutting, besides being a plant of a more accommodating size. *G. radicans* major is also desirable for its late-flowering properties. *G. citriodora* has blooms like Orange blossom; it is only a moderate grower, and should not be cut back, or very little. It requires care in potting, not disturbing the roots more than can be helped in removing the old soil. Flowers of this genus may be had throughout the year with these. Turfy loam with a little leaf soil or well decayed manure grows Gardenias well. Some growers prefer a mixture of peat and loam, but we have not seen the advantage.

Euphorbia splendens has gone out of date. No better plant for button holes has taken its place. It flowers continuously in a growing temperature, and is very durable. Being very bright in colour it is very useful for mixing with light-coloured flowers. No plant is of easier culture. It continues to flower whilst growth is being made. Afford plenty of light. Young plants potted and grown-on soon become useful. Only moderate pot room is required, good drainage being essential, and turfy loam with a little well-decayed manure and a fifth of sand and pieces of charcoal to keep the soil open. *Stephanotis* trained to the roof and done flowering should be cut back and have the old wood cut out. This will need to be regulated by the condition of the plants as to vigour, but whatever pruning is done it should be before the plants start into growth. It is important that the shoots be trained close to the glass beneath an unshaded roof, so that the growth be well ripened as it advances, for which no after-drying and parching can compensate. Those that are trained to trellises should have the shoots placed upon strings close to the glass in the full light, and only secured to the trellises to flower. Take care not to overcrowd, and keep clear of insects, especially mealy bug and scale, applying the remedy as stated for Gardenias.

Clerodendron fragrans started early will now or soon be out of bloom. It should be cut back to two or three joints below the flower spikes and placed in heat; it will soon break, and then should be fed with liquid manure. Keep free of red spider and mealy bug, the former by syringing on the under side of the leaves. *C. fallax* and *Kempferi* treated in a similar manner will afford a second crop of flowers.

Hibiscuses have gorgeous flowers. The plants should have encouragement, giving them light airy situations and keeping well supplied with water. They continue growing and flowering for a lengthened period. Turfy loam with a little leaf soil suits them well. Early-started plants of *Rondeletia speciosa* major will be in flower, and should be well supplied with water and kept free of insects, particularly thrips, to which they are liable, which is best done by fumigation or syringing well on the under side of the leaves. Remove the trusses of bloom as they fade to the leaves immediately beneath them and they will break and flower again soon, but if the shoots are cut back they will not do so. *Impatiens Jerdonis* is a useful decorative plant of small growth not often seen now-a-days. The plants should be grown near the glass, and must not be overpotted nor be kept too wet—indeed, they require to be kept rather drier than the majority of stove plants. When showing for flower water them occasionally with weak liquid manure. It does well in turfy loam with a little leaf soil and a free admixture of sand with thorough drainage. *Torenia asiatica* is a good plant for growing in pots to stand upon brackets or baskets; it is also very desirable for mixing with other plants in stands. Cuttings inserted now will flower in late summer and keep on for a long time.

Pot batches of *Achimenes* for late blooms. One of the best for late work is *A. ignea*, the flowers being very bright fiery

scarlet; sprays of it lighten up the dullness of autumn flowers immensely. Roof climbers must be frequently gone over, thinning and regulating the shoots, keeping them rather thin so as to permit the wood to get well ripened and induce a free-flowering habit. *Passifloras* should not be tied-in too closely, but the flowering shoots should be allowed to depend, in which way they have a much finer appearance.

Conservatory.—Flowering plants being less plentiful than at an earlier period the introduction of fine-foliage plants backed by flowering plants from the stove will allow a very effective display to be maintained. *Allamandas*, *Ixoras*, *Stephanotis*, *Bougainvilleas*, and *Clerodendrons* will endure a short sojourn in the conservatory without experiencing any injurious effect if kept for a time rather drier, cooler, and fully exposed to light prior to removal; but if brought from a hot moist stove without any preparatory treatment the plants will not endure as many days as they would weeks with proper treatment. Some of the higher-coloured *Dracenas*, *Crotons*, &c., are very effective; with *Coleus* they will be heightened in effect by well-grown plants of white-leaved *Centaureas*. Flowering plants, as *Fuchsias*, *Petunias*, *Liliums auratum* and *longiflorum*, *Plumbago capensis*, *Neriums*, *Zonal Pelargoniums*, *Campanula pyramidalis*, and *Humes elegans*; *Balsams*, *Cockscombs*, *Globe Amaranths*, *Hydrangeas*, *Achimenes*, *Gloxinias*; tuberous and other *Begonias*, as *fuchsioides*, *insignis*, *weltoniensis*, *Digswelliana*, *Dregei*, *Saundersiana*, *Ingrami*, *hybrida multiflora*, and others, tastefully arranged with the foliage plants will make a display little inferior to that produced earlier by more profuse-flowering plants. Climbers must be frequently gone over. The shoots of the *Passifloras* should be allowed to hang down. *Tacsonias* likewise roam at will, and they will not only look much better but flower very much more freely. Copious supplies of water and liquid manure, with thinning-out where too crowded and removing irregularities, is all that is needed. *Roses* of the *Maréchal Niel* type should have the old weak growths cut out, and every encouragement given to the young strong growths, which, if well ripened, will flower from nearly every bud. *Habrothamnus* should have the wood well thinned out, training so that the shoots can have plenty of light, and they will bloom grandly in due season. Tree Ferns can hardly have too much water, the stems should be well watered twice a day. Other kinds of Ferns should be well supplied with water and be moderately syringed. Plants liable to red spider, as *Mandevilla*, *Brugmansia*, &c., should be well syringed, applying the water with force so as to dislodge the insects, watering copiously at the roots and occasionally with liquid manure. *Neriums* must be well supplied with water; liquid manure will assist the buds in swelling, and the removal of the side shoots emanating from the base of the flower scape will materially help the swelling of the flowers.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

ADDRESS (*A Lover of Rose Shows*).—H. Neville, Esq., Chislehurst, is the Secretary of the West Kent Horticultural Society. We cannot find the query about manures.

PEAS SOAKED IN PARAFFIN (*Kittie*).—Soaking them for twenty-four hours would cause the defect you mention.

PRIZE FOR GREENHOUSE PLANTS (*Ipawitch*).—Stove plants cannot be exhibited for the prize. *Cissus discolor* is a stove plant.

BULB GROWERS (*Cymro*).—Ant. Roosen & Son, Overveen, Haarlem, Holland.

PLANTING ASPARAGUS (*T. Byrne*).—It is now too late to plant out Asparagus.

EUCALYPTUS GLOBULUS (*F. W.*).—This is hardy only in favourable situations as in Devon, Cornwall, the Isle of Wight, or the valley of the Thames. It will succeed in any good garden soil.

ERROR IN PRINTING (*A Correspondent*).—The error in our contemporary is amusing, but is not quite so extraordinary as one in which "simple plants" was printed instead of "small-pox."

FELLING CEDARS (*J. W. M.*).—The autumn is the time for felling. Cabinet makers are purchasers.

STRIPED AURICULAS (*A Northern Grower*).—A great many wonderful things were said to exist in former days, but in many cases they only did so in the imaginations of the writers. I have never seen anything like an approach to striped Auriculas. Double striped ones are equally unknown to me.—D., Deal.

ROSE BUDS DEFORMED (*R. Baxter*).—Defective root-action is the cause. More manure and a regular supply of water would probably prevent the deformity.

GERANIUM SEEDLINGS (*H. Tong*).—They are pretty, but not equal to many well known. Show them to some nurseryman.

CUCUMBER FOR EXHIBITION (*A Novice*).—Tender and True.

ROSE FOR A WALL (*M. B.*).—As you want a crimson Rose we advise you to plant Duke of Edinburgh.

SIZE OF PANSIES (*Old Subscriber*).—Show Pansies are seldom grown so large as 2½ inches in diameter. Some of the Fancy sorts are as large as this, but we consider 2 inches large for show varieties.

STRAWBERRIES NOT FRUITING (*Fulwood*).—If good plants were put out early last August they ought to bear some fruit now. It would all depend upon the treatment they receive. Some growers treat the Strawberry as an annual. The plants are put out in July or August, and they bear a very heavy crop the following season. If good-sized plants do not bear fruit it is best to root them out as cumberers of the ground.

FUNGUS ON ROSES (*P. B. W. L.*).—Your Rose tree is much infested with the black fungus, which may be checked by syringing the foliage with a solution of soft soap of a strength of 3 ozs. to the gallon of water, and afterwards dusting the parts affected with flowers of sulphur. In the winter prune your plant rather severely, cutting out the parts affected, and enrich the soil by applications of manure; apply also liquid manure copiously during the growing season.

MEALY BUG ON STEPHANOTIS (*R. H. Kay*).—Dissolve 2 or 3 ozs. of soft soap in a gallon of water, and with this sponge the leaves and every portion of the plant well, and afterwards syringe copiously and persistently with pure water. You will find other and excellent modes of destroying this and other insects in the present issue "Work for the Week" in another column.

CUCUMBERS FOR SEED (*W. S.*).—It is impossible to say how many fruits are required to produce an ounce of seed. We have at one time secured that quantity from half a dozen fruits, and at another not had half the quantity of seed from half a hundred fruits.

PACKING ROSES FOR EXPORTATION (*H. B.*).—For a voyage of only a fortnight no extraordinary precautions are requisite. Small plants established in pots might be packed with the pots in a hamper in the ordinary fashion, and larger plants should have the roots well enveloped in damp moss and the shoots tied securely together, and due care taken to prevent breakage. Early in November would be the best time.

SELECT FUCHSIAS (*J. S.*).—The following, in addition to those in your possession, are worthy of cultivation, and are inexpensive.—*Light*: Guiding Star, Venus de Medic, Minnie Banks, Mrs. J. Lye, Marginata, and Lady Heytesbury. *Darks*: Model, Noblesse, Killiecrankie, Knoch Arden, Victor Emmanuel, and Rhoderic Dhu. Your suggestion shall have our attention.

VINE UNHEALTHY (*R. Pine Lodge*).—From the description you give of the Black Hamburg Vine we consider its recovery extremely doubtful. We should dig it up at once and plant forthwith a healthy young Vine, which you can obtain in a growing state in a pot from a nursery not far distant from you. Give it some fresh soil, plant it carefully, not greatly disturbing the roots, water it with tepid water, and syringe occasionally, shading for a few days to prevent the foliage flagging. With good attention it will reach the top of the house this summer, and may bear a few bunches next year.

BAST MAT (*Vicar*).—The strictly correct mode of spelling the word is *bæst*, the Anglo-Saxon name of the inner bark of a tree.

PERIS TRICOLOR CULTURE (*Mr. Hamilton*).—Give this delicate Fern a lively stove temperature, avoid overpotting, using small pots with ample drainage, and afford it an open yet shaded nook by itself, and then by due attention to watering and cleanliness you will succeed. All the Pellaeas, or rather Platylomas, answer well in a greenhouse.

SOIL FOR GENTIANA ACALUIS (*Amateur*).—No difficulty should be found in inducing this old favourite to grow and flower freely in any tolerably rich garden soil. It answers best in deep rich loam, but we have numerous large patches of it growing freely in a somewhat thin light soil. Plant carefully, water till established in the soil, and then leave them alone, but do not expect an abundant crop of flowers till they have been established for two or three years. Make cuttings of your double Petunias forthwith, and you will have good plants for winter blooming, bearing much finer flowers than old cut-back plants would do.

PLANTS FOR CARPET BEDDING (*Caroline*).—*Grey and White*: Leucophytum Brownell, Santolina Incana, and Sedum glaucum. These are all grown solely for the beauty of foliage, and by their neat compact growth are well suited for such beds as yours. *Yellows*: Mesembryanthemum cordifolium variegatum, Sedum acre elegans, Coprosma Baueriana variegata. The first two are easily grown from cuttings, but the last is somewhat more difficult. All are established favourites of proved merit. *Crimsons*: Coleus Verschaffelti and C. Verschaffelti splendens; the first dark, and the last light crimson. *Greens*: Cerastium arvense, of very neat growth and a bright green hue; and Mentha Omen, a pretty variety of the old blue type. *Blues*: We have no substitute for the blue Lobelia, but if you have only tried speciosa you may like pumila grandiflora growing in the form of dense globular cushions. The Alternantheras are all pretty, A. amena and A. amabilis being general favourites, the first for its carmine foliage and the other orange red; but they require heat to keep them in winter.

CONSTRUCTING A VINERY (*Old Subscriber*).—Your aspect is an excellent one for a vinery, which we should construct and ventilate as you propose, not having it air-tight. We should, however, prefer having the house wider than 8 feet. Ten feet would be much more satisfactory if that width can be allowed, and in that case provide a width of 18 inches for ventilation at the top of the house, this being of glass instead of board. With good attention excellent Grapes could doubtless be grown in troughs as you propose; but a mistake or neglect in watering might not always be preventible, and then failure would ensue. A good border would be the safer and simpler plan to adopt. With two rows of 4-inch pipes the entire length of the house, not round it, Black Hamburgs would ripen perfectly, and four rows of pipes would afford sufficient heat for Muscats.

MANAGEMENT OF CUCUMBERS AND TOMATOES (*J. J.*).—Two things are requisite for the production of abundant crops of Cucumbers in the open air—an ample supply of rich soil for the roots, and plentiful waterings of sewage or liquid manure. No pinching or regulation of the growth is necessary. Tomatoes are equally fond of rich soil and sewage, and they also require to have the tips of the shoots nipped off one joint beyond every flower truss, and to have the foliage thinned when the fruit gets large in order to expose it fully to air and sunshine.

ROOT-PRUNING A PEAR TREE (*J. B.*).—The falling of the whole of the blossom of your General Todleben Pear tree is one of a thousand similar instances this year. Exercise a little patience, and do not hastily resolve to mutilate the roots of a tree planted only a couple of seasons ago. The fruit of this Pear is very large, and you can never hope to have it in full perfection on slender branches. Rejoice, therefore, in the "wonderful growth" which your tree has made this season; let the roots also grow freely, and perhaps next year you may have a little fruit, but do not be tempted to over-crop so young a tree.

SOIL FOR TUBEROUS BEGONIAS (*N. C.*).—The beds should be made of rich, light, gritty soil 9 inches to a foot in depth. The tall plants should be laid on one side, planting the ball of roots aslant, and then carefully spread and peg the branches, which owing to their brittle nature will snap asunder if you try to bend them.

FAILURE OF MELON CROP (*R. K. Penon*).—The failure of your Melon crop is probably owing to a low or fluctuating temperature, to improper ventilation, and very likely to a want of water. The condition of the foliage is attributable to the first two causes. We have long grown Melons successfully under similar conditions to those you mention with stone rubble over the pipes, and have always had plenty of roots sprouting out of the surface by the time the fruit begins swelling, when we then usually apply a slight surface dressing of fresh soil or give plentiful supplies of liquid manure. Do this. Cut off the decaying foliage; give a surface dressing of 2 or 3 inches of fresh soil; maintain a steady temperature of 75° to 80°; give air early, so that the foliage may become somewhat dry before the direct rays of the sun fall upon it; syringe freely on the afternoon of every sunny day till the blossom opens, and water carefully but thoroughly; avoid much wetting of the stems, around which scatter a handful or two of charcoal dust; impregnate the fruit blossom carefully; do not syringe them for a few days, slightly raise the temperature, and you will soon have a fair crop of fruit.

RAISING MULBERRY TREES (*Concha*).—They may be raised from seeds sown in pots in a hotbed, the seedlings being potted off singly, and after being hardened off in a cold frame planted out in rows 2 feet apart and 1 foot asunder in the rows; or they may be raised from seed sown in May outdoors, covering lightly with fine soil, and watering frequently through a rose watering pot as may be necessary. The seedlings will need protection in severe weather in winter, as mat-, &c. In March take up the plants, cut back to one eye, and plant as stated above. If you wish the trees for foliage more than fruit propagation from seed will answer your purpose, otherwise seedlings are much longer in coming into bearing than those from cuttings or layers. Cuttings may be made in autumn or spring, selecting the well-ripened growths of last year with a joint or two of two-year-old wood, inserting in light soil in a sheltered situation, leaving one, or at most two buds, out of the ground, watering if the weather prove dry, but avoid making the soil sodden. The Mulberry is also readily propagated from eyes, the well-ripened growths of the preceding year being cut into as many places as there are eyes, placing them on their side with the eye uppermost in fine soil covered half an inch deep, and keeping them moist. The buds soon grow, roots being emitted from the under side of the eye or wood. Layering in spring or autumn is also an eligible mode of propagation, taking a ring of bark off just below a joint.

MARECHAL NIEL ROSE NOT THRIVING (*M. C.*).—Our experience is that on its own roots this Rose is not at all satisfactory, especially when a strong growth is made, the plant having a tendency to a cankerous swelling just above the surface of the soil, which causes enfeeblement of the plant, it making very little growth and next to no roots. It is no better on its own roots grown in pots or planted out. It succeeds, however, admirably upon the Briar, and planted out makes shoots over 20 feet long in a season. We should procure plants upon the Briar, plant them out in the border at the back of the house, train the shoots up the back wall and upon the roof, and in due time you will be rewarded by glorious blooms in plenty.

CULTURE OF SARRACENIA PURPUREA (*G. W. O.*).—The plants may be "grown in a greenhouse, they being syringed every morning, and in a cold frame and covered with a bell-glass, watering overhead daily." We have seen them very finely grown in that way, but equally as fine or finer plants grown outdoors without any protection whatever as far north as York, grown in well-drained rough peat and watered overhead daily during growth. Supply the plant with sufficient moisture in dry weather, beyond this it may be left to itself safely in your Devonshire climate.

ROSE LEAVES SHRIVELLED (*F. A.*).—We have now for several seasons observed that certain Rose leaves curl and shrivel up as in your case. It is the result of extravasated sap, caused probably by cold currents of air on the delicate foliage, which promotes an unnatural contraction of the sap vessels. We have invariably found it makes its appearance first under or near large trees. Baronne de Maynard is with us very subject to it, but we have observed it also on the strong-growing Paul Neyron, &c.

PEAS DYING OFF (*A. N.*).—There may be several causes for your Peas growing so weakly. The seed may have been old, the soil may be poor, and the excessive amount of rain we have had may have affected them.

NAMES OF PLANTS (*H. H. C.*).—We think the Fern is Asplenium lanceolatum, but an abnormal frond. A. lanceolatum usually grows from 4 to 6 inches in height, and is distinguished from Asplenium Adiantum-nigrum, which it very much resembles, by the pinnae being set in pairs and almost at right angles with the main stem; while in A. Adiantum-nigrum the pinnae are generally set alternately. (*Horace*).—The Ceanothus is probably C. Veitchianus; as we thought, you had previously sent wrong foliage, that apparently of a Jasmine. (*F. H.*).—Calycanthus floridus. (*F. B. W. L.*).—Specimen too much pressed for identification. (*Constant Reader*).—Viburnum Opulus, var. (*Mrs. Podes*).—Celsia cretica and Erinus alpinus. (*X.*).—1, Geranium molle; 2, Ranunculus acris; 3, Vicia sativa; 4, Lathyrus Nissolia. (*R. Carnall*).—1, Syringa persica. (*J. E. F.*).—We would be glad to oblige you, but we cannot name florists' flowers. (*F. P. Hodges*).—Medicago maculata, or Spotted Medick. It is an annual, and the only way to get rid of it will be to mow it before it runs to seed. (*J. C.*).—Hyoscyamus niger.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HAY MAKING (FIELD HAY).

THIS is one of the most important subjects to be considered in the management of the home farm. We shall now only refer to the making of clover or field grass hay, hoping to treat of the making of pasture and meadow hay hereafter. Great improvements in the way of expediting the process of hay-making have become available during the past few years. Machinery has now

to a great extent taken the place of manual labour and greatly accelerated the process of making hay, without, however, reducing the cost very much as compared with the expense of manual labour previous to the invention of machinery. It must, however, be remembered that the price of labour at that time was much lower than at present. In those cases where the cutting, making, stacking, and thatching of hay is done by contract, the price per acre is not appreciably lower now than it was before machinery came into general use, particularly as it is now necessary to reckon the cost and interest upon and the repairs of machinery. It will certainly depend very much upon the extent of the home farm as to the propriety of the use of all the machinery required for the process of hay-making. Let us enumerate what is required to complete the items of machinery—first the mowing machine, next the tedding machine, the horse rake, the loader attached to the waggon, and the horse power, rick-making or elevating gear. Now, taking these machines altogether they will cost a large sum of money, and it must depend upon the extent of the land in occupation whether this outlay will be judicious or otherwise, at the same time calculating the rate of wages of men and women, or the possibility of obtaining sufficient hand labour in the neighbourhood to enable the work to be done with the celerity so desirable in the making of hay of the best quality. When we consider the great variations in our seasons under the best and most judicious management, the weather will always have much to do with the quality and condition of the hay. For instance, we will take the recorded rainfall in June and July of 1858, which was twelve rainy days, the depth of rain 4.99 inches; but in the year 1860, in June and July, we find that there occurred thirty-nine rainy days, the depth of rain being 7.65 inches. The contrast between these two seasons is extraordinary, 1858 being one of the best hay-making seasons, and the year 1860 one of the worst we can recollect during a period of fifty years. These two seasons serve to illustrate the difficulties which will often be experienced in saving hay, the fact being notorious that in a bad season inferior hay only can be expected, which will cost probably double or treble in the making and stacking as compared with the finest hay the result of a favourable hay harvest.

The age of the grass or state of growth at the time of cutting is of the greatest importance, not only as to the quality of the hay in a fine season, but its being able to take heavy rains in a wet time with the least injury. To effect this the grass should be cut just as it comes into bloom, at which time it contains the most juice and least woody fibre. No day of the month can be stated, because the blooming time will vary as much as eight or ten days in certain seasons, and the sorts of grass will differ also as to their blooming time. Much difficulty often occurs as to the best time for cutting grass when two sorts are grown together, each blooming at different periods. For instance, it is a common plan to sow the ordinary sorts of rye grass with broad clover. When this is the case they are never in blossom together, the clover being so much later than the rye grass. The exception, however, is Italian rye grass, which although earlier in growth than ordinary rye grass, is at least ten or twelve days later to bloom; therefore it is the only sort which will be fit to cut at the same time as broad clover and other late grasses, such as Dutch and suckling. In consequence of this we do not recommend the growth of ordinary rye grass in conjunction with broad clover, nor do we advise Italian rye grass as a mixture with broad clover, because, although it comes ripe at the same time, yet it has an injurious and overpowering effect on the growth of the clovers both in the first and second cuttings, and it prejudices also the following wheat crop. Having objected to rye grass with broad clover, we feel bound to recommend a substitute we always sow, and have done so the present seed time—mixed suckling with broad clover, which in the next course for the sake of alternation should be suckling in admixture with white Dutch clover; but for early cutting without reference to a second crop we prefer the yellow trefoil mixed with ordinary rye grass. These mixtures will blossom together, and it is only by adherence to this matter that the hay can be of the first quality, for if it is neglected one or other of the sorts will be cut to a disadvantage. Rye grass is usually grown with the clovers for the purpose of enabling the crop to be secured some days earlier than clover only; and allowing that it can be secured from three to four days quicker when rye grass is mixed, we claim that the mixture of suckling with clover will enable the hay to be secured from one to two days earlier than when broad or white Dutch is grown alone.

One of the points to be considered on commencing to cut the grass is, What are the prospects or probabilities as regards the weather likely to prevail during the hay-making season? We readily admit the variable climate we live in, and the difficulty of forecasting the weather. There is, however, a general rule in which we have found but few exceptions—viz., that when we get an abundant crop of grass we usually have a precarious time in which to make the hay. On the other hand, when we have a short light produce of grass we are generally enabled to secure it well. When there is a prospect of fine weather, as fast as the

grass is cut, if it consists of clover alone, we prefer to have it tedded by the hay-making machine, and the following day tedded again. The next day it may be raked into small windrows, to be turned the succeeding day. On the fourth day if the weather still continue fine the windrows may again be turned for the last time, as about the fifth day, except in the case of an extraordinary bulky crop, the hay will be fit to carry to the stack, and we prefer, instead of having it poked beforehand, to run it together with the pooking fork into large rows and cart it to the stack in a hot and dry state. By this mode of proceeding we have made the best and finest hay without losing the leaf of the grasses so essential to its value, whereas if the swathes are only turned the hay does not dry equally, the outsides of the swathes being crisp and brittle, and much leaf is lost. This may, however, be prevented to some extent by having the swathes turned every day until fit to carry, when it may be poked just before the carting, for we most decidedly object to pooking the previous day if the weather is ever so fine. Turning the swathes daily, however, involves much hand labour, as does also the turning of the windrows after tedding. Sometimes where hands cannot be obtained this system may be modified, but it cannot be done without if hay of the finest quality containing all the leaf with the stems of the grasses dried with regularity is required. Under this system we have, when the season has been favourable, made our Dutch and suckling clover hay in such a state as to resemble a sample of hops, especially when the grass has been cut before it comes into bloom, which is our practice if the hay is required for feeding the young lambs for sale in the London market. If our hay is only required for use on the farm or for sale for the feeding of horses and cattle, whether the grass consists of rye grass and clover mixed, or saintfoin, or the clovers alone, we adopt the plan of merely turning the swathes daily until sufficiently made. Another point is, When rain threatens is it best to run the swathes into pook or leave the hay in swathe? The latter plan is the best if the rain is only a passing shower, but the former is advisable if the weather glass portends a succession of wet days.

WORK ON THE HOME FARM.

Horse Labour.—The horses will yet be required in preparing the land for Swedes and turnips. Horse-hoeing of root crops, such as mangold wurtzel, carrots, parsnips, and cabbages, will be required for one or other of these crops continuously. The horse-hoeing of mangold and cabbage may be very well done when the land is sufficiently dry by the ordinary horse hoe with three shares or knives, the centre one to be a triangular or arrow-headed share; the knives being inverted and used on each side of the implement, and in the best-made horse hoes they are adjustable as to width. They have also been made convertible into double mould ploughs, available for stretching land for roots, and also for earthing-up potatoes. They have also in some instances a frame for digging and lifting the crop of potatoes, and when properly attached they answer the purpose very well. The horse hoe should also have three triangular arrow-headed shares to cut about 8 inches wide for the purpose of hoeing between the carrots and parsnips; and one horse will when three shares are properly arranged hoe the space between three rows of roots at one operation, because these roots to obtain the heaviest weight per acre are usually drilled at about 14 or 15 inches apart. The horse hoe will then move the ground sufficiently to enable the hand-hoeing to follow, which will be much facilitated thereby.

The horses will also be required to lay out manure if yard dung is applied as fast as the green crops are cleared. Whether the land is required for roots or the planting of cabbage the quicker it is done after the green crops are removed the better, because if the weather should become harsh and dry the land will work unkindly in some instances if allowed to lie too long after the crops are carried off. The carting and ricking of the early sorts of hay will now be going on, and this may be done by working after mid-day, the morning part of the day being occupied by working on the land for root crops, &c. At this busy time of the year we advise the making of hayricks in the field where it is produced, it being got together with much less labour as well as risk; because, whether the hay is required for sale or consumption on the home farm, any extra carriage will be done in the winter months, when the horse labour is not of so much consequence.

The odd horse or horses, according to the size of the farm and the requirements of the cattle, horses, &c., will now find ample employment, because when all the clover required for the team horses and the cattle is cut, as it ought to be, by the odd man, it will engage the odd horse for some time, and especially when we have added to this the border grass and that from banks, hedges, and ditches. Not only is this usually given to young cattle and pigs, but we know at this time a farm whereon the hedges and borders are so numerous that two men are almost constantly employed in cutting border grass and carrying it out in some cases for cartage between the corn fields. In the case of the fallow fields, the clover fields, and those now under cultivation for roots, the carts take it away as fast as it is cut. In the instance to which we refer twenty-five dairy cows are fed daily in the stalls, and have been so fed ever since the first week in May,

and fifteen young store cattle are fed in yards by the same means. Both these and the dairy cows get a moderate allowance of oil cake daily, all of which are in excellent condition, the cows yielding abundance of milk of good quality, which is sent off by railway to the metropolis daily. This is strictly an economical way of turning to account food which upon farms in general is wasted or must afterwards be removed at considerable cost in order to keep the fences and banks in a trimmed and decent state. But, unfortunately, when hedges, &c., are not sheared until the autumn then the weeds and coarse grasses will have deposited their seeds on the headlands and margins of the fields.

Hand Labour will now consist of mowing the clovers where the mowing machine is not used, and if it is so used some labour is required to cut the grass with scythe round the outsides and corners of the fields. Before the machine can commence work, when the weather is adverse, some men may draw the straw and have it properly stored away in readiness for thatching the ricks of hay. During the present week we have known rye which was cut for straw only carted to rick in sheaves, which will do either for thatching or for use in the winter as fodder for cattle. Some men are now required to prepare ashes by screening, in order to mix with artificial manures for Swedes and turnips; others are engaged in hoeing the mangold wurtzel, kohlrabi, &c.; and if the weather should continue wet and the weeds not die, as was the case in 1860 and 1861, the women should pick up the weeds by hand and heap them in the field, and this we have found the only way to keep the root land clean in an adverse season, and it is also cheaper than repeated and ineffectual horse and hand hoeings.

JAPANESE SILKIES.

THOUGH Japanese Silkies can hardly in size be classed among Bantams, whose weight they almost double, still they are so Bantam-like in their habits and good qualities that some account of them would seem a natural sequel to our notes on Bantams. It is not long since one of the first fanciers of the breed and best judges of it wrote upon Silkies in these columns; still it is not always easy to look back to the numbers of past years, and we know that the ranks of poultry fanciers have of late been largely increased, so we will without apology return to these quaint little natives of the far east. We confess to having once had almost an antipathy to them from their, at first sight, unnatural appearance with purple comb and black skin, but the possession of two or three, kindly given us some years ago, at once converted us into great admirers and fanciers of the breed. To be appreciated they must be known and kept. We spoke of Bantams as suitable for those whose premises are small; still more so are Japanese Silkies, for, in addition to their being contented with small quarters, they cannot fly above 2 feet high, and a fence of 3 feet will well keep them confined. They are hardy and very long-lived. Heavy rains and broiling sun they seem to dislike, but a very small abode will protect them; indeed we have seen them happy and flourishing in the smallest houses of amateurs' construction, like dog kennels. They are singularly quiet and good-tempered. A lot of cockerels will live peaceably together. The hens are good layers—that is, they will lay at all times of the year, and that regularly. In the late autumn we have often entirely depended upon our Silkies for eggs. They do not, however, lay many, seldom more than fifteen, before becoming broody; but it is as mothers that they chiefly excel. We have found them sit well wherever placed, and cover eleven of their own eggs, or thirteen Bantams'. They hardly ever crush an egg or chicken, and remain longer with their broods than almost any other hens. With those who rear delicate breeds of poultry, Pheasants or Partridges, Silky hens are always in demand as foster parents. So much for their utility; now as to their points of beauty.

They are particularly suitable to those who want a hobby in fancy poultry without having much spare time or much space to devote to it, for they mature rapidly, and are often fit to show at four months old. They hardly suffer at all from exhibition, owing, we fancy, to their contented disposition, for they never fret or pine in a pen. We have of late observed their classes poorly filled at some of the great shows; this must be the result of some unjust prejudice against them, or of ignorance of their merits. We have had Silkies imported both from Japan and China, and after comparing the best of these with the prettiest birds of the kind seen in England, and learning the opinions of the best poultry judges on them, we may confidently say that the chief points to breed for are the following:—Their general appearance should be very fluffy and silky, the hackles of the cock like spun glass, and the whole down in both sexes as soft as possible. We have seen bad specimens with harsh wiry down; this is very objectionable. Their general form should be round, with nice "cushions" rising from the back to the tail. The cock's sickles should be silky and fall nicely over from the cushion, not sticking stiffly up. The crests of both sexes should be of moderate size; that of the cock flowing backwards, that of the hen round and full. Their combs should be of mulberry colour, by no means reddish, rounded and rather smooth; in the hen quite undeveloped, but in the cock larger. It should on no account approach to the rose comb of a

Hamburgh with regular peak behind. Some years ago single combs often appeared among our chickens, we suspect from distant relationship to some other eastern breed, but we have now quite bred them out. Earlobes may be either of mulberry colour or bright torquoise blue; the latter are much the prettier, though in cocks they turn whitish and ugly with age. Their legs should decidedly be blue; they often have a green tinge, and an otherwise perfect bird, imported from China and kindly given to us by Mr. R. E. Horsfall, had green legs, but such are certainly an eyesore, and seem to go with green beaks and earlobes, which are very unsightly. It should be said that the legs of Silky chickens when first hatched often appear greenish, but become quite blue at two or three months old. Fashion or fancy has decreed that they shall have five toes; our own best imported birds have always had this number. Their legs, too, should be clothed all down with a nice even line of feathering, becoming thicker on the outer toes. Stiff vulture hocks are quite out of character with a round downy breed and should be discarded. There seems a tendency in the breed to increase its leg feathering, and we often find it necessary to breed from one parent with almost bare legs to counteract this. Beauty and utility should as far as possible be combined in every breed, and undue leg feathering would detract from the value of Silky hens as mothers, making them clumsy. Very small size, too, should not be sought, for Silkies are not Bantams, and this too would lessen their good maternal qualities.

We must not omit to mention their faults, which are very few. They are not good table birds; their skin and bones are black, and look by no means tempting; the flesh itself is white and good, so in the case of all faulty specimens we should advise that cockerels be killed early, and not cooked whole, but used for entrées, in which the skin need not appear. All imperfect pullets will find ready purchasers among Game preservers. Silkies are also subject to elephantiasis or scale on the legs. On its first appearance dress it well with compound sulphur ointment or Foster's ointment, and thoroughly cleanse the perch or floor on which the bird affected has roosted; it may thus easily be stamped out, but if neglected and allowed to increase it becomes painful to the bird and is infectious, so that even clean-legged varieties will catch it. It probably in the first instance originated from dirt. Silkies should, if possible, be kept on short grass frequently swept; their leg feathering will then keep clean and unbroken, and there will be little fear of this disease appearing.—C.

THE PARIS POULTRY SHOW.

WE promised to give some further notes on this interesting Exhibition, and now are able to keep our word. The great length of the Show has not been conducive to the health of the birds or to their general temperament. We have observed many of the more delicate kinds with drooping heads and closed eyes; and the absence of proper food for so long a time brings on unnatural cravings, such as the greedy devouring of eggs and feathers. But its duration is as it were an accident of the Show. We must turn to its national features.

We were somewhat astonished before the prize cards, or rather metals, were put up to see advertisement cards on the majority of the French pens, and men going about with similar cards in their hats touting for purchasers; in fact the Show was quickly converted into a market on a large scale. One good lady, who prides herself much upon the delicacy of flavour of her *La Flèche* and her system of fattening, not only tried day by day to induce us to carry home some of her pullets, but wished also to enlist us as an interpreter to represent to the English fanciers in the show yard the excellence of her breed. The mercenary side of the great contest, though at first contrary to our English ideas of a show, most decidedly has its advantages, for an immense number of birds seem to have changed hands, and that at moderate prices, German and other fanciers having come from far to buy English stock half way on to its destination. The English breeders, too, are not going home with empty baskets, and if we are not mistaken more and better *La Flèche* will appear in our coming shows than have been seen for a long time. Some of the rarer Polish, too, will come over the Channel. It will remain to be seen how the damper climate will suit them. Fancy poultry in France has not the same marketable value that it has in England; and we have heard it said in the *Eplanade des Invalides* that the market has there been spoiled for our countrymen by the too great readiness of a famed Yorkshire exhibitor to pay down the prices asked for some pens. To come more particularly to the classes.

The French classes were throughout very large. Of the eighty-five *Crève* cocks we certainly thought the two first-prize birds worthy of their place as splendid specimens. We preferred Mr. Fowler's third-prize hens to the other winners. Houdans numbered about eighty cocks and seventy lots of hens. We greatly liked Mrs. Vallance's second-prize cock; and her hens, which had only an honourable mention, were by far the best in their class, two of them being marvellous birds. We may here observe that though the number of hens for a pen is by the catalogue given as three, the French Judges admit four or more, and

even a cock as a supernumerary companion! This peculiarity much bothered the eyes of the English Judges. *La Flèche* had over fifty entries in each class. We never before saw such a collection. The French do certainly understand table poultry, and think much of smallness of bone. They are fully alive to the fact, that crosses with Asiatics spoil table fowls. The classes for *La Mans* and *La Bresse* were not large; the former we may here remark are large, square, black fowls with coarse rose combs; the latter much smaller, also black but with single combs and not unlike poor *Minorcas*. The classes for any other variety of French breeds were well filled with mongrels of diverse provincial types.

Cochins were interesting classes, and here a difficulty arose between the Judges of the two nationalities, for the French fanciers abhor the least tinge of red in a Buff *Cochin*, but do not object to meanness or even white feathers, while they prefer long legs; indeed, one of the French Judges constantly measured the height of the Buff cocks with his stick, and pointed out the advantage which a huge mealy-hocked bird had in this point. The said extraordinary specimen was first. It was arranged that first, second, and third prizes, parallel to the French awards, should be given to English birds of the English type; subsequently, to the disappointment of the English exhibitors' Judges, these were changed into "supplementary prizes," though with the value of first, second, and third. In White *Cochins* Mr. Darby utterly distanced all competitors, the Frenchmen being quite amazed at the beauty of the cock. In Blacks, too, he should have been first again, but the majority of French votes gave it to a cock with a crooked comb and much white in tail. The awards in Black hens were unaccountable; Mr. Darby's wonderful trio were objected to for one being "down behind." In the class for other kinds of *Cochins* nearly all went to Cuckoos. The French Judges proposed to disqualify all Partridges as a race unknown in France. Mr. Cresswell thereupon observed that "the English Judges understood that they came not to a French but to an International Exhibition." The retort had its effect, and Mr. Fowler's magnificent Partridge cock got a second and his hens a third prize.

Brahmas.—These two classes caused a most protracted discussion. French taste will not look at a pea comb, and only recognise the Light variety! All sorts of arrangements and compromises were tried, and at one time a single prize had been conceded to a Dark cock; but when the Jury came to the hens of the same variety it was too much for them, and a courteous Deputy of the French Chamber who was of their number most politely and good humouredly, yet steadfastly, refused to believe that they were of the same breed as the cock. Ultimately it was agreed to give prizes to both types as in the Buff *Cochin* cock class. In both sexes Mr. Norris was first with lovely Dark birds, in the one case Mr. Beldon and in the other Mr. Webb being very near him.

Dorkings were not well represented. In cocks the first and supplementary prize (given out of courtesy at the special request of the English Dorking fanciers) went to the best birds. In the hens three nice Silvers were first, though their colour was too rusty; and three Darks second.

Spanish were very fair. There could be little doubt about the first awards, which were excellent in both sexes; but all after that seemed haphazard work, beautiful hens of Mr. Fowler and Mr. Frounce being left behind two very indifferent pens.

In *Hamburgs* Mr. Beldon triumphed with a Gold-spangled cock and Silver-spangled hens. It should be remembered that in France Pencilled *Hamburgs* are called *La Campine*, and so should have been in the Variety class.

In *Game* Mr. Beldon was again first with a beautiful Brown Red cock. Bantams were shown together with large Game, and a smart little Duckwing cock from Mr. Entwisle's yard was second. In hens Mr. Beldon's Brown Reds were first in quality, but a general combat had spoilt their looks and put them out. They gave way to Mr. Entwisle's Bantams of the same colour. In these breeds we are far ahead of our neighbours.

Russian Malays were but small classes. Mr. Ridley's hens did not receive their due in a second prize.

White-crested Dutch (Polish) were not such classes as we expected to see. Mr. Darby's cock was easily first, and his hens would also have been so had not one of them unfortunately died before the judging.

Paduans were magnificent classes. We shall hope to devote a special article to them soon. First, both in cocks and hens, were good Buffs. The decisions in these classes are made rather misleading by the rule that an exhibitor may gain but one prize in a class. Most of the best birds came from two yards, and so some of the real winners do not appear in the prize list. Among the colours shown were Golden or Silver-spangled, *Ermine* (*Hermine*), or white with black specks on the neck and tail, pure White, Blue, and Cuckoo (the latter two varieties evidently not pure from their large combs), and Buff, also Buff-frizzled and White-frizzled.

The classes for "Any other variety" were immense, and here some extra prizes might well have been bestowed. In cocks a huge *Langshan* was first, a Brown *Leghorn* second, and a *Plymouth Rock* third. In hens, beautiful *Sultans* first, bad *Langshans* second, and a nice *Minorca* third. We thought some *Sultans* shown

by Mrs. Christy of Falkoners well worth an honourable mention, as also (which we forgot to mention) two pretty trios of Buff *Cochin* pullets shown by the same lady, whose only fault was their youth.

Turkeys were chiefly Black and not large. We saw nothing to equal Mr. Ridley's Bronze cock either in size or condition. *Geese* were fine, *Toulouse* beating the *White* variety in both sexes. Mr. Stott's two Grey *Geese* are simply marvels. We fancy they came from the renowned *Aylesbury* yards. *Ducks*.—The judging was in these classes simply ridiculous. The first drake was a miserable little thing, which could not weigh above 4 lbs.; second was the finest *Aylesbury* we have ever seen, and third a little mottled creature, which in any farmyard we should have picked out as a bad and degenerate specimen of the mongrel race. Magnificent *Rouens* and *Pekins* from *Aylesbury* were left out. The *Duck* awards were, if possible, more ridiculous than those for *drakes*. Three small yellow-billed *White* birds were first, little *Rouens* second, three brown under-sized creatures third, and the well-known gigantic *Aylesbury* birds fourth! There is much to be learned on both sides from such international contests.—C.

FERTILITY OF SWANS.

LAST year I wrote to you respecting a pair of Swans which laid nine eggs, and both birds sat at the same time on the one nest without result. I had not time to follow out your kind instructions, so let them alone, and this April they made a nest and laid a few eggs, which I took away. Altogether we have removed twenty-seven eggs. Fearing they might lay to exhaustion my man left one egg in the nest, and the next day another was laid, and for the last three weeks one of the birds has been sitting closely. Strange to say the other seems to be keeping watch, for if the Ducks on the lake approach the nest they are immediately driven away. Is not this an unusual number of eggs for two Swans to lay?—H. C.

TREATMENT OF RABBITS WITH LITTERS.

THE number of Rabbits that are born is very large, but the number that arrive at the age of two months is comparatively very small. We have noted that about three days before the event the hutch should be covered over a little so as to insure perfect quiet and warmth, and the mother should be provided with a little water or milk to quench the thirst natural at that period. The nest is beautifully composed, the groundwork being either hay or straw, according to the materials supplied. Each doe should be well supplied with both. Whichever is selected, care should be taken that it is soft. If hay, the sweet meadow variety should be selected. If straw, it should be soft and pliable, but quite dry. Rye straw will not do at all, being much too hard. The doe will tear it up into very uniform patches. She will carry lumps of it about the hutch in her mouth as though she were afraid of its being taken away from her. Finally she deposits it in the snugest corner in the sleeping room and piles it up, carefully arranging the tufts so as to get a soft surface. This she presses down to make it solid. The centre is a little hollowed out and is filled up with fur, which she tears from her body, chiefly from the breast. Sometimes the young are born a few hours after the nest has been finished, but in other cases the delay is greater. In a few instances the young have not been born till a week after the preparations have been completed. The young do not all come into the world at once, the births frequently extending over so long a period as twelve hours. In this case the process is weakening. Great quiet should be kept at this time. If the doe is disturbed during parturition or between the births she often either eats or neglects the young ones. An experienced breeder knows quite well when the process commences and what course to pursue; but a beginner may in his curiosity open the dark door, if he does so his litter may be considered lost. Of course the doe must be fed at such a critical time or she will suffer from weakness, but the food must be put into the big room quietly and quickly. As to the best food, succulent roots and leaves may be recommended, especially the former. A few soaked oats may be liked; a hot barley meal mash will be a great relief in case of a troublesome parturition; scalded peas will also make a nice warming meal. Warmed and sweetened milk will at all times be found satisfactory; it is a relief to the mother and aids the secretion of milk. Lettuces, wild parsley, and sow thistles also possess this tendency, and may be given in great freedom so long as the bowels are not relaxed. If there is any symptom of this sort a little less of the very succulent kinds of food should be given, and any mash should be well strained. For three days after the birth of the young ones the hutch front should be covered with a sack or other porous covering so as to keep out the wind and cold. Rats and mice are a great trouble at this time; Rabbits will not face either of these animals; rats will eat the young ones. The only remedies are to put the hutch on a small stand too high from the ground for jumping, or to have the wires so close that nothing can squeeze between. This is hard to do in the case of mice. The

young should not be looked at till they are a few days old. While the young are in the nest continually the mother must be very well fed, or she will suffer from the suckling. After about a fortnight the strongest of the young ones begin to evince an anxiety to see a little of the outer world, and walk or rather tumble into the open compartment. This is a critical time, as with all care the mother is apt to tread upon the little ones. Some mothers are very clumsy in this respect, and others are equally careful. The trough should be so placed that the young ones cannot get at it, as they would lie in it and spoil the food. When about three weeks have expired the nest may be taken away and the sleeping place carefully cleaned; supply with warm litter for the little ones. As the youngsters begin to feed care must be taken that they have such food as they can eat. The oats should be bruised or crushed before given and mixed with bran, which is a very good food for young Rabbits. Green food should not be given freely to them, but the mother should have plenty. The young should be shut away from the mother sometimes, so as to give her a chance to eat in peace. Too many young ones should not stop with each doe, because they weaken her very much. If the breed is a very large one the stronger young ones should be taken away first, so as to give the smallest a chance of improving their size.

—GETA.

VARIETIES.

AMONG the Jurors of the Royal Commission for the Paris Universal Exhibition of 1878 are for fermented drinks, H. Vizetelly, Esq.; cattle, Jacob Wilson, Esq. and H. D. Adamson, Esq.; sheep, Hugh Aylmer, Esq.; pigs, J. Ross, Esq., and L. S. Chrisp, Esq.; poultry, O. E. Cresswell, Esq., and M. Leno, Esq.; conservatories and horticultural apparatus, John Wills, Esq.

—OWING to the protracted dull weather and almost incessant showers haymaking in the south is at a complete standstill. We have seen crops cut and lying on the ground for three weeks, and the produce almost resembles manure. This is the more unfortunate, since the weight of the crops has been more costly than usual in the cutting. Twelve shillings an acre has generally been paid for scythework, and unless the weather changes and a term of sunny days occur that and other outlay incurred will have been thrown away. Where the crops have not been cut both grasses and clovers are decaying at the bottom, and managers of meadow land are sorely perplexed in consequence of the extraordinarily protracted dull and wet weather that is turning their produce into manure instead of hay. Hot and dry weather is urgently needed, or serious losses cannot be averted.

—THE United States is far in advance of any other country in point of agriculture, the development of this department of industry having been truly marvellous in late years. Thus the corn crop increased from 768,320,000 bushels in 1867 to 1,340,000,000 in 1877, or nearly 100 per cent. in a single decade. The hog crop, which may be said to be a product of the corn crop, reached the enormous total for the year ending with last month of 9,048,566 head, an increase of rising 100 per cent. during the last ten years. The yield of wheat for the past year was 360,000,000 bushels, or 50,000,000 more than was ever before produced. Deducting the amount necessary for home consumption and seed upwards of 110,000,000 bushels are left for export. In almost all other farm products there has been nearly a corresponding increase.

—WITH fine weather to follow from this time the crops, states the *Mark Lane Express*, may be fairly good, but they cannot be the great crops that were expected a month back. The wheats have lost colour and strength, the barleys in many instances have gone thoroughly to the bad, peas have grown weak, clovers have become rotten at bottom so that the hay made from them will be of poor quality, and mangolds on many farms have had to be ploughed up owing to the seed having rotted in the ground. It is a very moderate estimate to reckon farmers' prospects, on an average, at £2 an acre on all their arable land less than they would have been put at a month ago.

—PIGS IN THE UNITED STATES.—The American Commissioner of Agriculture gives the following as the number of pigs in the United States from 1870 to 1878 inclusive:—1870, 26,751,600; 1871, 29,457,500; 1872, 31,796,800; 1873, 32,682,050; 1874, 30,860,900; 1875, 28,062,200; 1876, 25,726,800; in 1877, 28,077,100; and in 1878, 32,262,500.

—A PROPER system of breeding lies at the foundation of all improvements in the production of meat. An eminent authority has justly remarked that "coarse, mis-shapen, unthrifty cattle cost just as much for rearing and fattening as those of the best quality, and yet may not be worth so much by £3 or £4 a head when they come ultimately to market." But this estimate places the question in a more favourable light than it deserves, for it takes longer time—that is, more food to fatten a coarse unthrifty beast than it does to finish one of better quality for market, and even when the coarse animal is fit for the butcher it is not worth so much per stone or hundredweight as the other. The authority from whom we have quoted further says: "The loss which is annually sustained from breeding inferior cattle is far greater

than those concerned seem to be aware of. It is impossible to estimate this loss accurately, but from careful observation and inquiry we feel confident that it amounts to not less than 50s. a head on one-half of the fat cattle annually slaughtered in Great Britain. If this be so it follows that without expending a farthing more than is done at present on food, housing and attendance, the profits that would accrue from using only the best class of animals would be equivalent to an advance of 1s. per stone in the price of beef, as regards half of the fat bullocks brought to market." An advance of 1s. per stone on half the fat cattle annually slaughtered in Great Britain would be equivalent to a gain of over three and a half millions sterling.—(*Irish Farmers' Gazette*).

BEEES AND BEANS.

THE theory advanced by Mr. Pettigrew on page 349 is new to me, but I do not on that account set it down as incorrect. I have to-day been examining the edge of a bean field of nine or ten acres, and we could scarcely take a step without seeing and hearing one or two honey bees at the blossoms. If the whole field was as full of bees as no doubt it was, there must have been many thousands there. The humble bees were very few. The honey bees attacked the blossoms both in front and rear—at the mouth and the spur—but I cannot say whether the same bee always went to the same part. The humble bees entered the mouth, and, as far as we could see, did not tap the nectary. If this were not sufficient to disprove the theory of the humble bees acting as tapeters for their smaller relatives, it would appear impossible for their small numbers to supply the multitudes of honey bees that haunt the bean fields, even if their movements were far more rapid than they are.

By-the-by, I venture to think that our vulgar name "bumble" bee is more expressive and better in every way than the more fashionable word humble bee.—J. BYRON, *Killingholme Vicarage*.

THE NATURAL AND THE ARTIFICIAL.

"NOTHING beats Nature" is an old and oft-repeated statement in agriculture, horticulture, apiculture, &c., Art assists Nature. Bee-keeping in this uncertain climate unassisted by the intelligence and hand of man would be a failure. But some people may think that to attempt bee-keeping in this country is a violation of Nature's laws—that bees here are not in their natural climate and element. This may be said of potatoes, celery, and turnips; but what were they in Nature's garden? Mere weeds or skinny vegetables. In grape-growing what has art not done? In profitable and successful bee-keeping the knowledge and hand of man lend assistance by giving stimulus to and playroom for the operations of Nature. Artificial comb foundations, artificial swarming, feeding, and uniting are resorted to in the management of bees.

The artificial comb foundations are a new invention not yet introduced to the great mass of bee-keepers. They have not, I fancy, been fully tested yet in this country. We have but little evidence to guide us in estimating their value. Records of experiments with them will doubtless appear by-and-by. Their price in retail houses is high at present. One correspondent stated that he paid 1s. 6d. per sheet of 18 inches by 12. It would take about eight or nine of such sheets to fill an ordinary sized hive. The cost of artificial foundations enough to fill an ordinary sized hive would be about 12s. Even if the bees adopt them readily and build upon them easily the question that arises is this, Are they worth this sum? Would the investment be a profitable one? We earnestly hope that some of our readers who have given the artificial foundations a fair trial will favour us with the results of their experience through the pages of this Journal.

Though we have not used artificial comb foundations we have frequently used natural combs artificially; that is to say, we have taken white virgin combs from large hives and fixed them in supers with great advantage and success. Natural combs thus fixed in supers and placed on hives tempt the bees to enter them at once and commence work. Can the artificial comb foundations be compared to the natural products of the bees themselves? Are they anything like equal in value or convenience to the perfect and beautiful productions of Nature? The comb foundations are perhaps as perfect as the hand of man can make them; but it should be known that they are but foundations without the superstructure of cells, and must be altered and reformed to some extent by the bees before cells can be built on them.

If we try to compare the cost of the natural combs with that of the artificial foundations we find a broad margin of gain on the side of the natural. Take a hive 16 inches wide by 12 deep, and fill it with bees from honey hives in September or October; give the bees 20 lbs. or 6s. worth of sugar, and they will fill the hive full of beautiful combs and store up about 20 lbs. of syrup. The 20 lbs. of sugar make about 40 lbs. of syrup, but 20 lbs. in weight are lost in comb-building. Take the bees out, and there remains a hive full of pure white virgin comb half filled with syrup: call it syrup honey. Of course this syrup honey should be removed from the combs before they are used for supering, and the only way of getting it out is to let the bees of other hives take it. If

the bees that built the combs be placed in an empty hive with an empty wooden super on it, and the hive with the syrup honey be placed underneath it, the bees will soon empty the combs, and with or from their contents secrete wax enough to fill the super with virgin combs. Thus perfect and beautiful combs, incomparably better than mere foundations artificially made, may be obtained for supering, and obtained at a much cheaper rate than the sheets of foundations at 1s. 6d. a piece. The use of a 16-inch hive is of course unnecessary in filling supers by artificial feeding. It has been mentioned here merely to give the reader an opportunity of comparing the cost of natural combs with artificial foundations. We sell run honey here more readily than honey-comb, hence supering is not our special aim. If it were we should endeavour to fill as many supers as possible with natural combs by artificially feeding the bees from honey hives late in autumn when little or no pollen could be found. Indeed it is possible to fill supers in a dark room or cellar by artificial feeding. Having confidence in the growing intelligence and ability of many of our leading apiarists, I believe they will adopt and develop the best means and ways of preparing supers acceptable to bees for the speedy reception of gluts of honey in favourable weather.

I shall not in this letter compare artificial swarming with the natural process; and as most bee-keepers have of late had enough to do with artificial feeding we shall hope that the weather will take a turn favourable for bees, and give them opportunities of gathering together large stores of the sweetest productions of Nature.

I am now on a visit to my native village, Carlisle, in the centre of Lanarkshire, where bee-keeping was successfully and profitably practised sixty years ago. The old race of bee-keepers have all passed away since my youthful days, but I am glad to find that bee-keeping is still successfully practised and is a source of pleasure and profit to many working people here. The pasturage for bees here is pretty good. Though my mission here is to seek health for myself, I have penned the above from a desire to write one letter on bees from the old place.—A. PETTIGREW.

THE CHLOROFORMED HIVE.

I HAD in December six fine full stocks, two of them Pettitt's bar hives and four straw, one of them 14 inches across. On examining my bees in February I found one of the bar hives dead, full of comb and honey, and only about fifty dead bees. I fed liberally with syrup for about three weeks, and five more prosperous-looking hives I never possessed. On each of the three small hives I have placed a large super, and to the bar hive I have added a 3-inch-deep bar box with a sheet of glass on the top. The last fortnight they have nearly filled the upper box with comb, and I suppose honey.

This hive was the one made from the three swarms I chloroformed in September last. I have had no swarm as yet (June 11th) from either of the five hives.—H. C.

OUR LETTER BOX.

FAILURE OF DUCKLINGS (*Aylesbury Pander*).—Monstrosities are more frequently met with among Ducks than any other poultry, but that would afford no explanation in this case. There appear to us only two probable causes for such misfortunes. If the eggs are set under hens and allowed to get very dry the young would all be exhausted and injured in their efforts to escape from the shell. If hatched under Ducks we must seek the cause in the feeding. Hard food is very bad for them just after hatching. Nothing is better than some oatmeal put in a shallow vessel with just sufficient water to float it. Where ducklings are hatched under Ducks they must not be allowed to go to the ponds. The old Duck takes them about into bad places, keeps them out too late seeking for flies and insects, and frequently leaves one behind. A hen with ducklings may be safely trusted with them at the water, as they remain on the brink where there is no danger. They also in this way pick up much food of the sort they require. The Duck part is always badly pitched with rough stones. The spaces between them are full of moisture. The ducklings delight to search these places, and do so to their benefit. If only one or two of your ducklings acted as you describe we should ascribe it to an injury sustained either by accident or wilfully from the hen or Duck; but that cannot be the case where all are alike affected. A hen with ducklings should be at liberty. Her brood do not understand scratching, and are often very much injured by a vigorous mother if she is in confinement. One might be killed daily in this manner till the brood disappeared, but the cause would soon be discovered.

RABBITS' EARS ULCERATED (*A. M. B.*).—This is caused by the Rabbits being kept in a confined and impure atmosphere. Dress the ulcers with sulphate or acetate of lead ointment, which you can procure from any druggist. Repeat the dressing till the cure is effected.

HEATHER AND LIME TREES (*A Killenny Bee-keeper*).—Lime trees flower before heather—the one in July, the other in August. Your bees, therefore, may be pastured on both. White clover is generally in flower before limes, and lasts till the heather begins to blossom. Lime trees do not continue long in flower, but the honey obtained from them is very clear with a rich aromatic flavour.

STRENGTHENING WEAK HIVES (*J. B.*).—"Having two hives of bees—No. 1 a very strong stock, and No. 2 a very weak one—I took each hive and placed them bottom upwards, and sprinkled them with syrup in which nutmeg had been grated. I then placed No. 2 on No. 1, and drummed on No. 1 for four minutes; then I placed them about 6 yards asunder. This was done

on the 29th of May, and they appear to be doing well. When may I expect swarms from these hives?" Answer: Hives should not be treated in this way. There are better ways of taking bees from strong stocks to strengthen weak ones. In the above experiment one or both queens may have been killed. If the queen of the strong hive run out of No. 1 into No. 2 one queen would be destroyed most certainly, and thus a greater loss than gain would result. The weak hive would be strengthened by the addition of bees; the strong one rendered almost worthless by the loss of its queen before it was ready for swarming. In the case mentioned drumming should not have been resorted to. When many bees of the strong hive were out it should have been removed out of sight to another part of the garden, and an empty hive placed on its stand. In about half an hour afterwards the weak hive should have been placed where the strong one stood, and thus a union would have been effected without risk of loss of queen. The placing the hives 6 yards asunder was right enough. We cannot say when your hives will swarm, or whether they will swarm at all this season. Examine both hives, and see if their combs are filled with brood.

ROYAL CELL. (*S. W. Fenn*).—There is a perfect royal cell attached to the bit of comb you have sent. The comb and cell are of this season's make, and the ragged edges of the cell indicate a queen has very recently come out of it.

PANS LINED WITH LEAD (*A. Boyle*).—They are dangerous if used either for milk or pickling pork.

GERMAN PASTE (*H. Buffham*).—Take 1 lb. of wheat flour or of pea-meal, 2 ozs. of fresh butter, 4 ozs. of brown sugar, three eggs boiled hard and chopped very small; put the flour or meal, with the butter, chopped eggs, and sugar into a wide saucepan over a slow fire, and keep stirring it to prevent its burning. When it gets dry continue stirring it until it becomes crumbly. When crumbly put a pint of cracked hempseed into the mixture, and mix well together. If burnt it is injurious to the birds. It will be good for months if kept in a dry cool place.

REMARKS.

- 12th.—Fair morning, very showery afternoon, fine evening, moonlight night.
13th.—Fine sunny morning, heavy hail shower 3.40 P.M., and continuous rain rest of the day.
14th.—Very dull and cold, but fair day.
15th.—Gloomy day; little sunshine at 5.30 P.M., dull but fair evening.
16th.—Fine morning, dull cloudy afternoon; thunderstorm in west from 1.40 to 2.40 P.M., rain after 6.30, but did not continue long.
17th.—Fine morning, slight shower at 1.40 P.M., fine afternoon and evening.
18th.—Very fine pleasant morning, cloudy and showery after 0.30 P.M.
Cold showery week, with frequent thunderstorms at various distances.—G. J. SYMONS.

COVENT GARDEN MARKET.—JUNE 19.

A CONSIDERABLE improvement has been experienced in our market, and all classes of goods have met with a more ready sale. Outdoor Strawberries have put in an appearance, but show evident signs of the miserable weather we are now troubled with. Early vegetables are lower.

From observations taken near London during forty-three years, the average day temperature of the week is 72.9°; and its night temperature 49.8°.

AMARYLLIS GROWING MADE EASY.

VOUR contributors who plead for Amaryllis growing, and the majority of those to whom they plead, can have little idea what simple treatment suits this gorgeous plant, and how really magnificent it is when grown under rational treatment, or the necessity for pleading would be non-existent.

When I see apologies appearing year after year for these very tractable plants because they refuse to throw up foliage contemporaneously with flowers, I can but wonder when the alternate starving and feeding system, productive of such unsatisfactory results, will be entirely banished from our gardens. The Amaryllis needs no drying off; it should never be stinted with water; it needs no shade and no stewing. Contrary to the dictum of many growers it does sometimes need a larger pot than a 7-inch one; at any rate, if the said growers will undertake to pot some of my bulbs into that size I will engage to alter my system, although I have now followed it for some nine or ten years and have reason to be not a little proud of the results.

An Amaryllis flower without foliage I cannot admire, however fine in form or beautiful in colour. You may place it among your choicest-growing Ferns, or you may cut it and arrange it with other flowers and foliage, but it is not satisfactory—nothing will do but its own handsome leaves. Even those of another variety will not do, for there is a great diversity of foliage. Some leaves are bronzed almost like an *Alocasia metallica*, another variety has light green leaves with a mealy-like bloom as thick as that on well-grown Alicante Grapes, some are sickle-shaped, and some are nearly straight and erect; but whatever their characteristics they all seem to harmonise so thoroughly with their respective flowers that it is very plain to me they were intended to be produced simultaneously with them.

Those people who can admire a cut Rose dressed with Maidenhair Fern I daresay would not object to see the Amaryllis in a similar garb, and to them I have nothing to say, except that I do not consider it good taste. On the contrary, not only is it necessary to have a Rose leaf with a Rose bloom, but it is often necessary to be particular about the kind of leaf. The foliage of Madame Lacharme, although perfectly suitable to the flower of that variety, will not do along with one of *Triomphe de Rennes*, and probably the foliage of *Triomphe de Rennes* would not look quite the thing with any other flower but its own. It may be thought that it is only fancy, or only because we know certain Roses as much by their foliage as by their flowers, but it is nothing of the sort; a perfectly strange flower with unsuitable foliage, both of which may be very beautiful in their proper places, would offend the eye just the same. We could tell there was something wrong if we could not tell exactly what it was. The effect produced would be somewhat akin to that we should expect from seeing two people of opposite character—say a modern High Church cleric and a genuine navy dressed in each other's

clothes. But this subject of foliage, in relation to flowers must not tempt me further. I have endeavoured to show that it is necessary to have the right sort of foliage for certain flowers, and now I will try to prove that the Amaryllis can be flowered better and easier with foliage than it can without it.

I have more than a hundred plants, and I believe every one of them has flowered since last November, many of them more than once, and I only remember seeing one which had not ample foliage. They are unfortunately not named, but there are probably a dozen distinct varieties, crimson, scarlet, and scarlet and white predominating. A bright crimson variety, a single bulb, had two scapes over 2 feet high with six flowers on each scape at one time. A scarlet and white one measured 8½ inches across the mouth of its flower in a natural position. A scarlet and greenish white grows 3 feet 3 inches high and flowers abundantly; in fact they all grow and flower vigorously, but as I have no opportunity of visiting other places in winter or spring I have no chance of comparing mine with those grown by other people. Visitors here, however, have admired the size of my bulbs and flowers, and from what I read I am convinced that many who take more trouble than I do have a less amount of success.

The Amaryllis is nearly hardy, and probably would be quite so if we could persuade it not to start so early into growth. My plants are all outside and have had no protection since the beginning of the month; they did not even go through the ceremony of being hardened off, but were brought direct from a vinery when the Vines were beginning to shade them too much. They will remain outside till there is danger of severe frost in autumn, then to be taken into a cold house or pit; even a shed would do for a time. They are usually taken into a house where Strawberries and Roses are started in December or January at a temperature of 50° to 55°. Meanwhile, though they have never been stinted with water, they will have ripened thoroughly, even in a cold wet season like the last one, and most of them will have lost their foliage but not their roots; these will be as vigorous and fleshy as ever, and it will require but a very little excitement to start the flower scape. When the tip of this is just visible you may do anything with them except shading them. Let them remain where they are, or place them in the hottest house you have, it will make little difference except as to their time of flowering; the foliage will start growing immediately after the scape, and by the time the flowers appear all will be in proper proportion. The foliage of course must be taken great care of, and the later in spring it is produced the less trouble will it be.

From what I have said I think it will easily be seen that those who have a vinery or greenhouse could easily grow Amaryllises better than three parts of the people now grow them in hothouses; and be it remembered my vineries are not hothouses, 55° being the average minimum temperature for all Grapes, including Muscats, till after the flowers are set. The Amaryllis does not often need potting, once in two or three years is sufficient, but it must have rich lasting food; turfy loam, half-inch bones, and a little

charcoal suit it well. The roots should be disturbed as little as possible, and should never be checked in any way.—**WILLIAM TAYLOR.**

THE VINES AT CHISWICK.

I OBSERVE in your note on page 429 that the Grape crops at Chiswick are unusually fine this season, and that Mr. Barron attributes the striking improvement in the Vines to copious supplies of water. On this point I would like to remark, that from experience and observation gathered from practising in the very wettest and the very driest of districts, I feel convinced that in districts where the rainfall does not exceed 36 inches per annum Vines rarely ever get as much water at the root as is good for them, and have far too much supplied to the atmosphere of the vineries by sprinklings. Where the drainage of Vine borders and the soil are as they ought to be I have never known Vines suffer from too much water in their growing season, and have known them get 6 feet of rain in the year, besides artificial waterings in inside borders amounting to even more than 6 feet.

While referring to the subject of Vines I should also like to remark that I fear your correspondent "KITCHEN GARDENER" (page 441) leaves Scotland and the north of England out of his range of vision when he so confidently advocates the growth of Grapes without any fire heat. Scotland is not so very inconsiderable in Grape culture now-a-days. I fear, however, if Grape culture were attempted in unheated houses it would soon be a thing of the past, except in some favoured spot in exceptionally fine seasons. It would be well in advocating such conditions for Grape culture not to recommend their application to the whole country, for in the greater part of the north, and I suspect the north-west of Ireland as well, it is calculated to mislead when such unqualified recommendations are so confidently urged.—**D. THOMSON, Drumlanrig.**

NOTES ON ROSES.

I SHOULD strongly doubt the truth of a recent statement that Sénateur Vaisse is "a seedling from Général Jacqueminot." I should say he has nothing of the Jacqueminot strain. Sénateur Vaisse came out in 1859 (Guillot père), and the seed of a particular Rose will produce the same Rose unless, either by Nature or by Art, it has been hybridised. John Hopper seems a special favourite with this writer. "We have got," he says, "one first-class English Rose of pre-eminent beauty and fulness, though it bears the somewhat prosaic and plebeian name of John Hopper." This is rather strong. The Rose is a very excellent one, though not to be trusted for exhibition. But how about Devoniensis, and Cheshunt Hybrid, and Duke of Edinburgh, and Prince Arthur, and the Laxton strain? and so I might go on. Our English-raised Roses are now, very generally, the best in the new catalogues. He goes on, however, to tell a pretty story about the origin of his favourite, which, to me at any rate, is entirely new. "A poor market gardener and floriculturist in the eastern counties for years carried on a series of experiments in Rose culture, the cost being supplied by a patron in the shape of a well-to-do tradesman in a neighbouring county town. At last the Rose in question made its appearance, and in gratitude and by way of compliment to his patron, who was the means of enabling the producer to realise a little fortune, it was after him christened John Hopper." The writer remarks further, and certainly with much truth, that Rose fanciers, like the Athenians of old, "are always yearning for something new." He then indicates a real want—"not merely a rich creamy yellow, but a true yellow, like the Persian yellow double Briar." The double Provence, sometimes called the Burleigh, is still the only really good colour of this class which has any decent substance. We are also told a curious fact. "So great is the present mania for Roses that it is calculated the public spend at least £100,000 per annum in this popular flower." The article ends with a lament that "the Rose of all flowers most keenly resents the smoky atmosphere of our metropolis." I am not quite sure that this is altogether the case. We shall soon see. One of the Secretaries of the National Rose Society has taken town-bred Roses under his special protection. The schedule of the Society for the great Show to be held at the Crystal Palace on June 29th (Class 13) shows a prize of plate, besides three other prizes, offered by E. Mawley, Esq., for "Roses grown within eight miles of Charing Cross," and the number is limited to six, which should really stir up suburban gardeners.

How much now depends on the weather? and how many hours of sunshine have been registered lately? Cucumbers have been defined as "bottled sunbeams." It is much to be wished that the patent for extracting sunshine from them should soon be at work. Perhaps in these days, when they bottle up our conversation, even such a process need not be utterly despaired of, otherwise with such sunless summers we shall be having the first prizes go, as last year at the Crystal Palace, to Roses under glass. There is a grim pleasantry in the concluding sentences of our contemporary:—"June has hitherto been but a dull month, but lovers of the Rose have an advantage over other persons in that they can console themselves with the consciousness that a hot sun is an enemy to their favourites!" "There is a medium between painting the face and not washing it."—**A. C.**

P.S.—I think the suggestion of "A LOVER OF ROSE SHOWS" (page 461) a very excellent one, and shall be happy to give any Roses I may have at the National Rose Show at the Crystal Palace on June 29th for any hospital to any properly authorised person. Apply at 5.45 P.M.—**ALAN CHEALES.**

BLACK JAMAICA PINE APPLE.

AFTER an extensive acquaintance with this Pine Apple I have come to the conclusion that it is the best Pine in cultivation. The fruit does not grow very large, as it seldom exceeds 4 lbs., and very often averages between 2 lbs. and 3 lbs.; but it does not take a large-sized fruit to weigh this, as there is no Pine weighs heavier for its size than the Black Jamaica. It does not produce so many leaves as the Queen, consequently it can be grown in less space, or I might say three Jamaicas can be grown in the space required for two Queens. It is not at all a shy fruiter, as it generally fruits at from fifteen to eighteen months old. It also produces suckers much freer than the Smooth-leaved Cayenne. The most notable part of the Jamaica, however, is the fruit. The flesh is always exceedingly firm, more so than any other. Under ordinary cultivation it is very juicy, and the flavour is so rich as to exceed all others in either winter or summer. We are sometimes complimented on our Pines, and this is always after a Jamaica has been sent to the table. In many places the Jamaica is only grown as an odd sort, but it deserves more than this, and, in addition to the qualities named, it will keep longer than any other kind after it is ripe.—**A KITCHEN GARDENER.**

FRUIT PROSPECTS.

THE appearance of the fruit trees here in the early part of the season was most promising for an abundant crop of fruit of everything excepting Pears, which had but a scanty show of blossoms. Apricots, which were in bloom about the middle of March, suffered much from the severe frosts from the 22nd to the 25th. On the 24th there was a severe frost and snow-storm, followed by a heavy rain, and the following morning the trees were covered with a sheet of ice. Those protected suffered equally with those unprotected, and from 150 yards of wall I do not think there will be ten dozen of fruit. Peaches and Nectarines protected and unprotected are a good crop, but best where protected by coping boards as well as nets. Cherries are only partial; on north aspects a fair crop; Morellos especially good. Plums, particularly Green Gage and Victoria, an enormous crop; other kinds good, but not so heavy as the two before-named. Standard Plums, more particularly Prince Englebert, Pond's Seedling, Orleans, Yellow Magnum Bonum, and Golden Drop, a fair crop. Damsons a failure. Gooseberries a very light crop, but making up in size; some Warringtons on the north side of the wall the best. Currants, both Red and White, good; Black a heavy crop. Raspberries looking remarkably well, and Strawberries most promising. Standard Apples in some positions good, in others only a tenth of a crop. Bush Apples better than has been known for years. The Apples which have the best crops are Hawthornden, Blenheim Orange, Sturmer Pippin, Kedleston Pippin, Lord Suffield, King of the Pippins, Court-Pendu-Plat, Braddick's Nonpareil, Forge Apple, Quarrenden, Winter Nonesuch (?), Cox's Pomona, and several others which I have not had an opportunity of testing, as I found them named when I came here. I must not omit to mention that Dutch and Keswick Codlins are good both as standard and espalier. Amongst Pears Marie Louise on the walls, Jersey Gratioli, Beurré d'Amanlis, and Williams' Bon Chrétien are the most prolific.

Caterpillars have been very destructive to the foliage of

both Pear and Apple trees, but the trees are now recovering from their ravages. Taking the fruit crop altogether it is the best that has been seen at this place for several years. The heavy rains are acting very beneficially to all trees, causing them to make abundance of clean healthy foliage, and should it be a good season for ripening the fruit and wood I anticipate a satisfactory exhibition of fruit.—J. GADD, *Thorndon Hall, Essex.*

YORK FLORAL FÊTE.

JUNE 19TH, 20TH, AND 21ST.

YORK was *en fête* last week. The ancient city held its festival of flowers. For a number of years flowers and fruit have formed the chief feature of an entertainment which has been enjoyed by vast numbers—all classes in the city patronising a gathering which in all respects is so worthy of their patronage, and dwellers in the adjacent towns and district giving also their countenance and support to an enterprise which affords them so much real pleasure and wholesome relaxation from the sterner duties of life. The floral *fête* is evidently a holiday which has the sympathy of the citizens, for in streets far distant from the Show ground flags were plentifully displayed in honour of the occasion. It is not a matter of surprise that flowers should be appreciated by the citizens, for York is, to a much greater extent than many large towns, a city of gardens. In all parts of the city trees abound—not in formal lines in the streets, boulevard fashion, and according to the order of an æsthetic municipal authority, but rather in that free, happy, English, informal manner, where individual taste is exercised in the planting of trees and flowers wherever soil below and light and air above have suggested sites that should be occupied in a manner that imparts both beauty and health to any populous district.

Where individual taste is thus reflected in a town it follows as a matter of course that public and official countenance should be given to that which is in all respects so beneficial—namely, the rendering of open spaces cheerful and attractive. The magnificent cathedral, now undergoing extensive repairs, is a pile not only of which the city but the nation may be proud, and its majestic proportions have fitting relief by the ample lawns and bold clumps of trees with which it is surrounded. Similarly, too, the churches in various parts of the city are rendered, as they always should be, cheerful and inviting by having their enclosures, be they ever so small, cared for and kept and cherished. Not at York do we find the churches surrounded with dilapidated gravestones at all angles, mossy and miserable, nor docks and nettles battling for supremacy, nor walks green and unkempt; no, at York all is happily different—smooth lawns, well tended evergreens, neatly kept flower beds and borders, and clean walks are the appropriate accessories to the several churches of the city, and their condition is such as to merit warm commendation.

The Show, or, as it is termed, "The Grand Yorkshire Gala, Floral, and Musical Exhibition," was held in the Bootham Field, an enclosure of 12 acres, contiguous to Bootham Gate, one of the arched entrances through the ancient wall. A glance at the arrangements of the tents told that a crowd was expected, not only by the ample space provided in the several marquees for promenade, but by the substantial barriers erected for the protection of the plants. Usually we find a few stakes inserted in the ground at intervals, and a length of rope stretched from stake to stake to preserve the plants, &c., from injury. Occasionally we have seen the fruit further protected by wire netting, an arrangement that is not pleasurably suggestive; but at York there was no caging of the fruit, and the protection was simply placed to preserve the collections from the crush and pressure of the thousands of visitors. The barriers were formed of stout posts firmly affixed in the ground, and from post to post stout battens 3 or 4 inches square were nailed, forming a continuous line of fencing throughout the tents strong enough to resist the rush of a bullock. Yet the appearance of the guards was not by any means clumsy, for the rails were first covered with white calico, then strips of blue were wrapped round the top rail diagonally and regularly, which quite took off the heaviness which otherwise would have been produced.

The tents in which the Exhibition was held were also correspondingly stout; they were also lofty and capacious. The central tent was a circular one, very large and lofty, and from this radiated five other marquees, each about 150 feet in length. The exhibits were principally arranged down the centre, with narrow tables also along the sides. One tent was devoted chiefly to fruit, Orchids, and cut flowers; another to Roses; a third to Pelargoniums and Fuchsias; a fourth to stove, greenhouse, and bedding plants; and the fifth to ornamental-foliated plants and Ferns. The centre of the large circular tent was occupied by the chief specimens of stove and greenhouse plants and exotic Ferns, and the sides by hardy Ferns. Provision was thus made for a great Show, and a great Show it was, but by no means a full one, for the officials had to regret what is so often, indeed far too often, the case—that much space was taken by exhibitors which they never utilised.

So much for the scope of the Show, now to its character. It was a Show of extremes. Some classes were exceedingly strong, others extremely weak. Very liberal prizes were offered in some of the classes, and it is noteworthy that where the prizes were the largest the competition was the smallest. For instance, in the open class for twenty stove and greenhouse plants, where the prizes were £25, £15, and £10, only one collection was staged—namely, by Mrs. Cole & Sons, Withington, Manchester. This was, no doubt, the result of excluding exhibitors in that class from competing in the classes for six and three plants. It is only just that local exhibitors should have a reasonable chance of securing a fair share of the honours at a local show; still it is clear that if grand specimens of hardwooded plants especially are required at York, inducements must be offered such as to warrant distant exhibitors bringing them. Local growers can and did stage softwooded plants admirably. Ferns and ornamental-foliage plants exhibited by "home" growers were very good indeed, Fuchsias were excellent, Pelargoniums splendid—equal in quality to the best exhibited at the Pelargonium Show in London, and greater in numbers, and bedding plants were staged as well if not better than we ever saw them exhibited. A "bid" was made for Messrs. Turner's and Paul's grand Roses, but the £20, £12, and £10 were offered too late. The Yorkshire gardeners, however, staged Roses in pots very creditably, much better indeed than any which have been exhibited in London this year. The season was too early for cut Roses, which were generally poor, and it must be added poorly set up. Fruit was an important feature of the Show; the display was one of the most extensive of the season, and many excellent collections were staged. Cut flowers, bouquets, epergnes, &c., were with one or two exceptions not superior. Such is the general character of the Show; we will next refer to some of the chief classes, making no pretensions to refer to the whole of the numerous exhibitors who were awarded prizes.

STOVE AND GREENHOUSE PLANTS.—The chief prize in the chief class was won as we have observed by Mrs. Cole & Sons. The twelve flowering plants consisted of three *Ixoras*, *I. Williamsii* having remarkably fine heads; three *Azaleas*—Mrs. Fry, *Magnificent*, and *Criterion*—well-bloomed pyramids 6 feet in height; *Erica* obbata, *Dracophyllum gracile*, *Allamanda nobilis*, *Franciscæa confertifolia*, *Statice profusa*, and *Hedera* *multiflora*; the eight foliage plants comprising three large *Crotons*—*Weismannii*, *variegatum*, and *angustifolium*—the latter a fine specimen in brilliant colour, *Pritchardia filifera*, *Cycas Normanbyana*, *C. revoluta*, *Dicksonia antarctica*, and *Latania borbonica*. Most of the plants were superior, and the collection was an excellent one. The principal prizes in the amateurs' classes were won by Mr. Noble, gardener to T. Fry, Esq., Woodburn, Darlington, with medium-sized, healthy, and well furnished specimens; J. Rhodes, Esq., and G. Talbot, Esq., Southfield, Burley, Leeds, who were placed in the order of their names. For six stove and greenhouse plants in bloom W. Dove, Esq., Crown Cottage, York (Mr. R. Berry, gardener), was first. A large specimen of *Rhynchospermum jasmynoides* was well flowered; *Clerodendron Balfourianum*, *Statice profusa*, and *Anthurium Scherzerianum* were also well grown. Mrs. Ringrose came in second, a large well-bloomed plant of *Lapageria alba* being noticeable in this collection.

FERNS.—In the central tent also there were grand collections from O. G. Wrigley, Esq., Bridge Hall, Bury (Mr. Hubbersty, gardener), and Mrs. Cole & Sons, who were awarded the prizes for eight plants in the order named. Mr. Wrigley's plants comprised four magnificent *Gleichenias* 6 to 8 feet high and through, *Davallia elegans* 4 feet, *D. Mooreana* 6 feet, *D. polyantha* 5 feet, and *Cibotium Schiedei* 4 feet in diameter. Mrs. Cole's plants were *Cyathea dealbata*, 7 to 8 feet spread of fronds, *Thamnopteris australasica*, *Cibotium Schiedei*, a fine specimen having a spread of 7 to 8 feet, *C. regale*, and three *Gleichenias*—*apellunæ*, *Mendelii*, and *rupestris* about 3 feet in diameter and in splendid condition; a collection of very great merit. The third prize in this class was won by Mr. Raper, gardener to J. Rhodes, Esq., Potternewton House, Leeds. In the class for four exotic Ferns Mr. Woods, gardener to A. Wilson, Esq., Anlaby Hall, won first honours with very good examples of *Dicksonia squarrosa*, *Adiantum concinnum latum*, 3½ feet, *Davallia Mooreana*, and *Gleichenia rupestris*. J. Rhodes, Esq., was placed second with more irregular specimens, and Mr. Cottam, gardener to Mrs. Ringrose, Cottingham Grange, Hull, third. For a pair of Tree Ferns the prizes went respectively to F. W. Tetley, Esq., Weetwood, Leeds (Mr. Eastwood, gardener), and W. Dove, Esq., Crown Cottage, York (Mr. Berry, gardener). The first-prize pair were *Cyathea dealbata* and *Cibotium princeps* with stems of about 4 feet and good heads. Hardy Ferns were numerous, and the specimen plants were very good yet by no means equal to the luxuriant examples staged at Manchester. In the class for twelve plants Mr. Scott, gardener to J. Buckle, Esq., York, was in the premier place with fresh and good specimens of *Osmunda regale cristatum*, *Scolopendrium vulgare crispum*, several varieties of *Athyrium*, *Polystichum* and *Lastrea*, and *Trichomanes radicans*. The second and third prizes were equally divided between E. J. Lowe, Esq., Highfield House, Nottingham, and Mr. Rodwell, Burton Lane, York. Amongst Mr. Lowe's plants *Athyrium Filix-femina* Lowii and *Lastrea Filix-mas* var. *cristata angustata* were

particularly striking. Mr. Rodwell had a good plant about 3 feet through of *Asplenium marinum*. For six plants J. Buckle, Esq., was again first, E. J. Lowe, Esq., second, and Mrs. Ringrose third; and for thirty-six plants Mr. Rodwell came in first, E. J. Lowe, Esq., second, and W. R. Robinson Esq., 102, Lowther Street, Groves, York, third. These were shown in a small state and contained many rarities. Lycopodiums were fairly fresh and good, but far inferior to the splendid cones exhibited at Reading and the large flat specimens staged at Manchester. The prizetakers at York were Messrs. Dove, Buckle, and Wilson.

ORNAMENTAL-FOLIAGED PLANTS.—These were admirably exhibited, first honours for eight plants going to Mr. Lazenby, gardener to Mrs. Pease, Darlington, with *Alsophila excelsa*, large; *Thrinax elegans*, very good; *Cycas circinalis*; *Croton majesticum*, 6 feet by 4; *C. Disraeli* nearly 5 feet high, fine; *Geonoma gracilis*, 4 feet; a *Dasyllirion* and a variegated *Yucca*. Mr. Fry had the second prize with a good collection, and Mr. Wilson the third, an extra prize being awarded to Mrs. Ringrose. In the class for five plants Mr. Winterbourne, gardener to T. Simpson, Esq., Bardon Hill, Weetwood, Leeds, was placed first, Mr. Wilson second, and Mr. Rhodes third, all staging meritorious collections. Mr. Wrigley was awarded an extra prize for a well-cultivated collection of *Sarracenias*, &c.

PELARGONIUMS.—These were both numerous and excellent, quite the best we have seen at any local show; indeed the Zonals were equal to the best exhibited in London, and the Shows and Fancies were also of remarkably good quality. In the class for twelve Show varieties Mr. May, Hope Nurseries, Bedale, won first honours with splendidly grown plants 3 feet in diameter, with luxuriant foliage and massive flowers in good colour; Messrs. Lazenby & Sons being second with smaller but good specimens, and F. W. Tetley, Esq., third. For six plants F. W. Tetley, Esq., came in first; Mr. J. H. Oliver, gardener to Miss Steward, Bishopthorpe, York, being a good second. F. W. Tetley, Esq., was again first for three, with capital examples of Mary Hoyle, Patroness, and Rose Celestial. T. Simpson, Esq., Bardon Hill, Weetwood, Leeds, was second; and Miss Steward third. In the classes for three and six Fancy varieties the first prize also went to F. W. Tetley, Esq., for splendid plants, foliage and blooms being alike excellent. Mr. H. May was a very good second; and Messrs. Lazenby & Sons third. The last-named firm won the chief prize in the class for nine French and English spotted varieties, such as Bridal Bouquet, Hiawatha, Triomphe de St. Maude, Lavinia, Duchess of Edinburgh, Lord Raglan, Mrs. Bradshaw, Digby Grand, and Huntsman. Double-flowering Zonals were well represented. The best lot of six came from Mr. R. Simpson, New Lane, Selby, the varieties consisting of Victor Lemoine, Imperator, C. Glijm, Madame Lemoine, Mons. R. Abel, and Madame Michael Buchner. They were sturdy specimens and well bloomed. Mr. A. Simpson, Heworth Nursery, York, was second; and Mr. Key, Clifton Nursery, York, third. For three double varieties F. W. Tetley, Esq., came in first with well-grown plants of Auguste Villaume, Madame Lemoine, and Emily Laxton. The class for six Zonals brought out a strong competition, the plants all being dwarf, large, healthy, and floriferous. The best three were Rose Rendatler, Princess of Wales, and Grand Duke, from F. Simpson, Esq. G. Talbot, Esq., was second; F. W. Tetley, Esq., third; and Mr. R. McIntosh, gardener to J. T. Hingston, Esq., Clifton, York, fourth. For six Nosegays the first and second prizes went to F. W. Tetley, Esq., and J. T. Hingston, Esq., who both staged splendid plants; while for three Zonals G. Talbot, Esq., came in first with well-bloomed specimens of Rosamond, Mrs. Gladstone, and Mrs. Tetley; F. W. Tetley, Esq., was second; F. Simpson, Esq., third; and J. T. Hingston, Esq., fourth. In the class for six plants the awards went to T. Simpson, Esq., F. W. Tetley, Esq., and J. T. Hingston, Esq., who all staged well-grown plants. The first-prize plants were 4 feet over, and were not more than a foot high from the surface of the pots to the level of the flowers. The Tricolor and Bicolor sections were plentiful in numbers and of the best quality. The first prize for the best three Tricolors went to Mr. J. Gibson, gardener to T. S. Lightfoot, Esq., Askham Bryan Hall, York, who had specimens of Mrs. J. Clutton, William Sandy, and Flambeau, nearly 3 feet over, and perfect in growth and colour. The other awards went to W. T. Walker, Esq., A. J. Cholmeley, Esq., Newton Hall, Rillington, and Mr. J. Hemmings, gardener to Mrs. Jackson, Pocklington. For six plants W. T. Walker, Esq., was first with admirably grown plants of Italia Unita, Countess of Craven, William Sandy, Charming Bride, Lady Cullum, and Lass o' Gowrie; and the second awards went to Mrs. Jackson; T. S. Lightfoot, Esq., and Mr. R. Simpson being equal third; and Mr. A. Simpson fourth. Bronze Zonals were both numerous and superior. In the class for six Mrs. Jackson came in first with well-developed plants of Reine Victoria, W. E. Gumbleton, Imperator, Maréchal McMahon, Vicar of Wakefield, and Earl of Rosslyn. Mr. R. Simpson was second; and T. S. Lightfoot, Esq., third. It is impossible to speak too highly of the admirable cultivation displayed by the several exhibits in those classes.

The FUCHSIAS made a central row down the Pelargonium tent, and were much better than we usually see them now-a-days, being

healthy well-bloomed pyramids 6 to 8 feet high, and 3 to 4 feet in diameter at the base. J. T. Hingston, Esq., was first with Rifleman, Puritani, Rose of Castile, Sir Colin Campbell, Queen of the Sea, and Arabella, all good sorts for specimens. Mr. Clark, gardener to Miss Wharton, Burton Grange, York, was a good second; and Mr. Duggleby, gardener to M. Varvill, Esq., St. Mary's, York, third.

ORCHIDS.—These were not exhibited in large numbers, but the first-prize half-dozen of O. O. Wrigley, Esq., Bridge Hall, Bury, were splendid examples of culture—the cream of the magnificent collection which won premier honours at Manchester, and which are enumerated in our report of that Show on page 444. Mr. Wrigley was also far in advance of other exhibitors in the class for three plants. Other successful competitors at York were J. Ritson, jun., Esq., Headingley, Leeds, and J. Rhodes, Esq.

ROSES.—Liberal provision for these was made in the schedule, and a considerable number of plants were exhibited—sufficient, indeed, to nearly fill one of the large tents. Mr. May, Hope Nurseries, Bedale, won the chief prize for twenty plants, Mr. Pybus, Ripon, being placed second with dwarf well-bloomed specimens 2 to 3 feet in diameter. For twelve in 8-inch pots the prizes went to Mr. J. Pybus, Mr. H. May, and Messrs. Jackson and Co., Cross Lane Nursery, Bedale, in the order named. For six in 8-inch pots Mr. J. Douglas, Daveygate, York, was first; F. W. Tetley, Esq., second; and J. T. Hingston, Esq., third, Miss Steward taking an extra prize. F. W. Tetley, Esq., was also first for three. The plants staged were highly creditable to the amateur cultivators, the blooms being fresh and fine, and the foliage healthy and clean. The date was evidently much too early for cut Roses, which, except in the case of the nurserymen's collections and the Teas staged in competition for Messrs. Cranston & Co.'s prizes, were poor. The best amateurs stand in the Exhibition was undoubtedly that of E. R. Whitwell, Esq., which won the first prize offered by the great King's Acre firm. The varieties were Belle Lyonnaise, Souvenir d'un Ami, Madame Hippolyte Jamain, Madame Berard, Jean Ducher, Maréchal Niel, Gloire de Dijon, Alba Rosea, Madame Bravy, Caroline Kuster, Madame Margottin, and the gem of the collection, Marie Van Houtte. The blooms were fresh and clean, and were arranged in a box covered with black velvet. E. Brooschott, Esq., had the second prize. Mr. Oldroyd, gardener to C. Grimston, Esq., Kilnwick Hall, Cranswick, Hull, was first for twelve Tea-scented flowers, and also for twelve Hybrid Perpetuals; and E. Brooschott, Esq., took the highest honours for eighteen, while A. Wilson, Esq., contributed the best twelve white and yellow blooms. In the nurserymen's classes the flowers were much better, yet by no means superior. For forty-eight single blooms Mr. H. May, Bedale, came in first, Messrs. Paul & Son, Cheshunt, second, and Mr. House, Peterborough, third. For thirty-six singles Messrs. Cranston & Co., Hereford, were first, Mr. H. May second, and Messrs. Paul & Son third. For twenty-four varieties, three trusses of each, Messrs. Paul & Son and Messrs. Cranston & Co. were placed equal first, and Mr. H. May third.

There was nothing noteworthy in the classes for bouquets and table decorations, the exhibits generally lacking elegance and refinement. Neither were the collections of cut flowers superior, except the first-prize stand of twelve varieties staged by Mrs. Cole & Sons, which was the best we have seen at any exhibition this year. It was composed of four bunches of *Ericas*, two of *Allamandas*, three of *Ixoras*, two of *Azaleas*, and one of *Anthurium Scherzerianum*. The same exhibitors secured chief honours in the class for six table plants with small and elegant examples of *Aralia Veitchii*, *Chamædorea elegans*, *Croton majesticum*, and *Cocos Weddelliana* (two). O. O. Wrigley, Esq., and A. Wilson, Esq., had the remaining prizes with excellent collections. There was considerable competition in this class, but the plants, except those in the winning collections, were much too large for table ornaments.

Bedding plants were wonderfully well exhibited by Mr. R. Simpson and Mr. Dove, who were awarded the prizes in the order named for sixteen varieties exclusive of Pelargoniums. The plants were exhibited in pans 2 feet in diameter, and were altogether excellent. Mr. Simpson also had the chief prize for an admirable collection of Alpine and herbaceous plants. Messrs. Backhouse and Son offered prizes for eight Tuberous Begonias. The plants were poor, and the first prize was rightly withheld by the Judges.

FRUIT.—The display was both extensive and excellent, but the dull season had left its mark on the Grapes, many of which were not well coloured, still it was the best exhibition of fruit that has this year been arranged, and occupied a length of 150 feet of staging. The coveted prize—the Veitch memorial medal and £5—for three bunches of Black Hamburgh Grapes was awarded to Mr. A. Ferguson, gardener to B. Shaw, Esq., Cowick Hall, Selby, with symmetrical bunches of about 2½ lbs., full, and well coloured, but containing many very small berries. Colour must at all times weigh strongly with judges, but for once we thought too much importance was attached to it. By far the better Grapes were those exhibited by Mr. Westcott, gardener to the Duke of Cleveland, which were regular in size, very fine in berry, and "hammered;" they were, however, not quite black, while those that

superseded them were black, but smooth and glossy, and several of the berries were little larger than Marrowfat Peas. It was no doubt a difficult class to judge, and Messrs. Hunter of Lambton and Henderson of Thoresby were long in deciding, and could only get out of the difficulty by granting Mr. Westcott an extra prize. There were seven competitors in the class.

In the class for six varieties of fruit eight good collections were staged, the prizes being awarded in the following order:—First, Mr. Gilbert, gardener to the Marquis of Exeter, Burghley Park, Stamford; second to Mr. McIndoe, gardener to J. W. Pease, Esq., M.P., Hutton Hall, Guisborough; and third to Mr. Bannerman, gardener to Lord Bagot, Rugeley. Mr. Gilbert's collection comprised two good and well-ripened Pines, good Black Hamburgh and very large bunches of Trebbiano Grapes, a splendid York Herald Melon, and large and well-coloured Royal George Peaches and Elruge Nectarines. The Grapes in Mr. Pease's collection were very fine—4-lb. bunches—but not well coloured, and the fruit of Read's Scarlet Melon was very handsome. In the third-prize collection the Peaches and Nectarines were excellent. In the class for four dishes nine collections were staged, and of such equal merit were those belonging to Mr. J. W. Pease and Lord Bagot that the first and second prizes were added together and divided between them. The collections consisted of excellent Grapes, Melons, and Peaches and Nectarines. Mr. Woods, gardener to A. Wilson, Esq., Anlaby Hall, was awarded the third prize. The best three Queen Pines came in the following order—from Mr. Lettis, gardener to the Earl of Zetland, Upleatham; Mr. Noble, gardener to T. Fry, Esq., Woodburn, Darlington; and Mr. J. H. Clayton, gardener to J. Fielden, Esq., Grimston Park, Tadcaster. The black Grape class was a very good one, and here the Duke of Cleveland came in first with small but remarkably well-finished bunches of Black Hamburgh. The next came from Mr. Allsop, gardener to Lord Hotham, Dalton Hall, Hull; and the third-prize lot from C. A. Thelluson, Esq., Brodsworth Hall, Doncaster. Lord Hotham came in first in the corresponding class for white Grapes with a beautifully ripened dish of Buckland Sweetwater; Muscat of Alexandria from Mr. J. A. Todd, gardener to T. H. Preston, Esq., Moreby Hall, York, coming in second; and J. W. Pease, Esq., third with good bunches of the same variety quite green. For a single dish of new Grapes J. W. Pease, Esq., was first with Madresfield Court; the Marquis of Exeter second with Golden Queen; and Lord Bagot third with Dr. Hogg. Peaches and Nectarines were excellent. For Peaches the Duke of Cleveland was first with Dr. Hogg; Mr. G. Purdy, gardener to J. T. Leather, Esq., second with Grosse Mignonne; and Mr. R. Taylor, gardener to Sir J. Ramsden, Bart., third. The Marquis of Exeter sent the best dish of Nectarines, a well-coloured sample of Elruge; Lord Bagot the second, a capital dish of Down-ton; and the Earl of Zetland the third—Stanwick. In the class for Scarlet-fleshed Melons the Marquis of Exeter was first with York Herald, a deep-fleshed plant of good quality and nicely netted; Mr. J. Atkins, gardener to Col. Loyd Lindsay, Lockinge Park, Wantage, second with Read's Scarlet-flesh; and F. W. Tetley, Esq., third with Hero of Bath. Mr. J. Clarke, gardener to the Marquis of Ripon, sent the best green-fleshed variety, the Rauceby Hall of splendid quality; J. W. Pease, Esq., the second best, a beautiful fruit of Golden Gem; and the Marquis of Exeter third. Lord Bagot was first with Figs, showing the Lambton Castle Seedling; and C. A. Thelluson, Esq., first for Strawberries with a very good dish of Sir J. Paxton. Sixteen brace of Cucumbers were exhibited, the chief prize going to the smallest—a new variety named Verdant Green, raised and exhibited by Mr. McIndoe, gardener to J. W. Pease, Esq. It is the result of a cross between Telegraph and Monro's Duke of Edinburgh, and most resembles the latter. It is an excellent table fruit about 15 inches long.

The Show was well managed by Mr. Wilson, the industrious Secretary, and an active Committee, and the prize cards were affixed with great promptitude.

SELF-REGISTERING FLOWER POTS.

FREQUENTLY after potting a new plant, or cutting, or seedling, especially if it has a long name, and that besides the date may be worth noting, I find it inconvenient to have new labels to hand (and old ones until washed and repainted are worthless), and have adopted the expedient of writing the name and anything I wish to remember on the side of it. This has suggested to me the idea at the top of these few lines for want of a more accurate description. Gardeners are generally hurried, and if they are not at this season they ought. Would it not, then, be a great convenience if, instead of looking for metal, galvanised iron, zinc, or wood labels, one had nothing to do but pencil the name, &c., along the side of the pot? What a saving of time, labour, convenience, and it may be of patience and future possible annoyance, this would be!

But then I may be asked what I would suggest. I am not sure if the idea is fully practicable or has already been adopted;

if not, then some of your readers may make a fortune by it. But seriously, could not Japan or some suitable composition be used to mark a space around the middle of a pot, and a suitable marking pencil be procured? The Japanning could be washed without injury and re-marked for a new plant as before, thus relegating dirt, labels, and bad printing among things obsolete.—W. J. M., *Clonmel*.

ALEXANDRA PALACE ROSE SHOW.

JUNE 22ND.

FORTUNATE in having a brilliant day, an immense number of visitors assembled at the Palace on Muswell Hill to inspect, criticise, and admire the Roses arranged in the Concert Hall. No place in England is better adapted for a Rose show than the Hall in question, provided the day is sunny. The light is then just sufficiently subdued to show the blooms to great advantage and is also regularly diffused; the room is also deliciously cool, which preserves the freshness of the Roses until the close of the Show.

We did not expect to find an exhibition at all equal to the superior shows of the past two years, as the date, considering the cold sunless season, was too early, especially for the Manettis, which usually yield the finest yet the latest blooms. But although not equal to the display of last year, still the Show was a good one; indeed, many were the expressions of surprise both as to its extent and excellence; quality, however, decidedly preponderated over magnitude. Mr. C. Turner and Mr. Cant, who had both entered in several classes, were unable to compete in consequence of heavy hailstorms having injured their blooms, but most others of the old exhibitors both among nurserymen and amateurs were well represented, and a few new competitors shared in the honours of the day. The Show was well managed by Mr. J. S. Cooke, one of the Palace officials.

The schedule was divided into three sections, five classes being provided for nurserymen and six to amateurs, four prizes being awarded in each class; the remaining nine classes were "open."

NURSERYMEN.—In Class 1, for seventy-two single blooms, there were four competitors, who were awarded the prizes in the following order—First, Messrs. Paul & Son, Cheshunt; second, Messrs. John Keynes & Co., Salisbury; third, Messrs. Curtis, Sandford, and Co., Torquay; and fourth, Messrs. Mitchell & Sons, Uckfield. The Cheshunt Roses were remarkably fresh and fine, and were considerably in advance of the other collections. The following were the varieties—Annie Wood, splendid; Abel Grand, really grand; Marie Baumann, excellent; Henri Ledechaux, fine; Fisher Holmes, Elie Morel, Charles Rouillard, Madame Victor Verdier, François Michelin, Souvenir d'un Ami, Olivier Delhomme, Comtesse de Serenye, good; Duke of Teck, Madame Hippolyte Jamain, Beauty of Waltham, very fine; Mdle. Marie Finger, Paul Verdier, Jean Ducher, remarkably good; Madame Prosper Langier, Marguerite de St. Amand, Madame Gabriel Tournier, coarse; Centifolia Rosea, a beautiful bloom; Madame Lacharme, fine; E. Y. Teas, very good; Princess Beatrice, fine; Mdle. Marie Rady, Etienne Levet, Ferdinand de Lesseps, Clotilde Rolland, Souvenir de la Malmaison, Mrs. Baker, Niphotos, Prince de Portia, Duc de Morny, Xavier Olibo, Capitaine Christy, Madame Clemence Joigneaux, Eugene Verdier, fine; Duke of Edinburgh, Devonensis, Victor Verdier, Rubens, very large; John Hopper, Marquise Adelaide de Murinais, flat; Duchesse de Caylus, Edouard Morren, Nardy Frères, Emily Laxton, Camille Bernardin, Cheshunt Hybrid, La France, Mrs. C. Wood, Dr. Hogg, rich claret; Madame Willemoz, Marquise de Castellane, Charles Lefebvre, splendid; Duchesse de Vallombrosa, very good; Sénateur Vaisse, Madame Caillat, Général Jacqueminot, Miss Poole, Devienne Lamy, Sultan of Zanzibar, Duchess of Edinburgh, Madame Nachury, Mrs. Laxton, good; Marchioness of Exeter, fine; Horace Vernet, Lælia, Madame Treve, and Mrs. G. Paul. The darker colours were very rich in this excellent collection, and the lights pure and clean. The best of the Salisbury Roses were Marquise de Castellane, Général Douai, Alfred Colomb, Charles Lefebvre, and John Hopper. The Torquay collection, which was a remarkably close third, contained splendid blooms of François Michelin, Madame Hippolyte Jamain, Le Havre, La France, Madame C. Wood, and Camille Bernardin, but the remaining blooms were small. Many of the Uckfield Roses had been considerably injured by adverse weather.

In the class for forty-eight triplets only two collections were staged, Messrs. Keynes winning first, and Messrs. Paul and Son, Cheshunt, second honours. They were not at all easy to judge. Freshness was pitted against size, and freshness won. It is not necessary to enumerate the varieties, for the best were those specially noted as superior in the preceding class. The next was a much better class—namely, twenty-four Hybrid Perpetuals, three trusses of each. Five very good collections were staged, and the prizes went as follows:—First to Messrs. Cranston & Co., King's Acre Nurseries, Hereford; second, Messrs. Paul & Son; third, Messrs. Keynes & Co.; and fourth, Mr. G. Cooling, Bath. The Hereford blooms were very fine throughout, the best, however, being Beauty of Waltham, La France, Madame

Furtado, Louisa Wood, Annie Laxton, Miss Hassard, Marquise de Castellane, Maurice Bernardin, Duke of Edinburgh, and Comtesse de Serenye. The Cheshunt collection was a very close second. Sultan of Zanzibar was very rich, and highly superior were Mrs. Laxton, very close and symmetrical; Mons. E. Y. Teas, La France, Princess Beatrice, Annie Laxton, Madame Lacharme, and Duchesse de Vallombrosa. The notable blooms in the Salisbury collection were Etienne Levet, La France, Marquise de Castellane, Alfred Colomb, Marguerite de St. Amand, splendid; and Fisher Holmes. Very fine in the Bath contingent were Star of Waltham, Duc de Rohan, almost black; Madame Victor Verdier, and Charles Lefebvre.

In the class for twenty-four single blooms seven collections were staged, all of them containing many good Roses. Messrs. Cranston & Co. fairly won first honours with Louisa Wood, Comtesse de Serenye, Marie Baumann, Madame Fillion, Madame Furtado, Mdle. Eugénie Verdier, Madame Lacharme, Madame Ferdinand Janin, L'Esperance, Charles Lefebvre, fine; Souvenir d'Elise, a charming bloom; Annie Laxton, excellent; Duke of Edinburgh, Madame Laurent, Souvenir de la Malmaison, Marquise de Castellane, Horace Vernet, Devoniensis, Exposition de Brie, Duchesse de Vallombrosa, La France, Maurice Bernardin, Comtesse d'Oxford, and a very fine Lælia. Messrs. Curtis, Sandford, and Co. were second; Mr. G. Cooling, Bath, third; Messrs. Keynes and Co. fourth; an extra prize being awarded to Mr. W. Rumsey, Joyning's Nursery, Waltham Cross, who all staged fresh collections, but many of the blooms were deficient in size.

We now come to the class for twelve Tea-scented or Noisette Roses, in which there was excellent competition, and the seven collections staged attracted much attention. Messrs. Mitchell and Sons won first honours with an admirable stand, most of the blooms being of great substance and very pure. They were Maréchal Niel, Comte de Paris, Devoniensis, Souvenir d'un Ami, Jean Pernet, Souvenir de Paul Neyron, Elise Sauvage, beautiful; Duc de Magenta, a charming bloom; Madame Margottin, Adam, Marie Van Houtte, and Joséphine Malton, flesh suffused with pink, a fine bloom and very beautiful. Messrs. Paul & Son, Cheshunt, had the second place with Cheshunt Hybrid, very fine; Alba Rosea, Madame Berard, a lovely bloom; Marie Van Houtte, equally charming; Narcisse, Niphetos, Perle de Lyon, Souvenir d'un Ami, and Catherine Mermet. Messrs. Cranston & Co. were third, and Messrs. Keynes fourth; but many of the blooms were more or less injured and discoloured.

AMATEURS.—In the class for forty-eight single blooms five collections were staged, the prizes going in the following order:—First, R. N. G. Baker, Esq., Heavytree; second, T. Jowitt, Esq., The Old Weir, Hereford; third, Joseph Davis, Esq., Wilton, Wilts; and fourth, John Hollingworth, Esq., Turkey Court, Maidstone. Mr. Baker's blooms were fresh, bright, and had good foliage; but the celebrated amateur is not yet in his best form, several of the Roses being small. The finest blooms were Mons. E. Y. Teas, Madame Victor Verdier, Charles Lefebvre, Baronne de Rothschild, and Princess Beatrice. The lights—Marquise de Mortemart, large and flat; Madame Caroline Kuster, Madame Hippolyte Jamain, Madame Lacharme, Madame Bravy, and Duchesse de Vallombrosa, greatly enhanced the attractiveness of the collection. Mr. Jowitt's blooms were generally smaller but very fresh, notably La France, Duke of Wellington, Marguerite Brasseur, Marie Baumann, Etienne Levet, and Mons. E. Y. Teas. The gem of Mr. Davis's collection was Marie Van Houtte; Marquise de Gibot, Sir Garnet Wolsley, and Sénateur Vaise were also very good. Five collections were also staged in the class for thirty-six single blooms, and J. L. Curtis, Esq., Chatteris, Cambridgeshire, won the first position with blooms remarkably bright, but rather small and admirably set up. The best were Mons. Noman, Jean Cherpin, Horace Vernet, La France, Marie Baumann, Marie Van Houtte, Duke of Wellington, Etienne Levet, Ville de Lyon, Devoniensis, Mdle. Marie Rady, and Mons. Furtado, all lovely three-quarter-expanded blooms. In this class Mr. Curtis achieved a feat which places him in the front ranks of exhibitors, for he was followed by Mr. Baker and Mr. Jowitt, who were respectively awarded the second and third prizes, the fourth going to J. Hollingworth, Esq., Turkey Court, Maidstone. In the next class for twenty-four triplets Mr. Hollingworth was placed first and Mr. Joseph Davis second. The collections were almost equally good, but the blooms were irregular. Six collections competed in the class for twenty-four singles. John Edwards, Esq., Stisted Rectory, Braintree, was first with an excellent collection, but some of the blooms were too much expanded. The cream of the stands were La France, Devoniensis, Maurice Bernardin, grand bloom; Charles Lefebvre, wonderfully rich in colour; and Marie Baumann. John Sargent, Esq., High Street, Reigate, had the second prize with a capital stand containing splendid examples of Maurice Bernardin, Mons. E. Y. Teas, Charles Lefebvre, La France, Marquise de Castellane, Comtesse de Serenye, and Comtesse d'Oxford. Mr. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, was placed third with a collection containing the best blooms of Emilie Hausburg and Sénateur Vaise in the Show, also good examples of John Hopper, La France, Madame Victor Verdier, and Charles Lefebvre. Rev. E. L. Fellowes, Wimpole

Rectory, Royston, had the fourth prize, the Rev. J. B. M. Camm, Maurice Bernardin, and Auguste Rigotard being excellent in this collection, and an extra prize was awarded to J. Graveley, Esq., Cowfold, Sussex, La France, Rubens, and Anna Ollivier being in superb condition.

In the class for twelve single blooms eleven collections were staged—nearly all of them good, and some very fine. John Edwards, Esq., won the chief prize with a capital stand containing Charles Lefebvre, remarkably rich; Marquise de Castellane, large and good; John Hopper, Maréchal Niel, fine; Marie Baumann, splendid; Souvenir d'un Ami, Paul Verdier, Capitaine Christy, Thomas Mills, Niphetos, lovely; Etienne Levet, fine; and La France. Mr. Ridout had the second place with a collection of nearly equal merit, in fact only two points behind the other. Charles Lefebvre was splendid, and excellent also were Madame Victor Verdier, La France, Marquise de Castellane, and Comtesse d'Oxford. Third honours went to J. Wakely, Esq., Church House, Rainham, with some massive blooms of Hippolyte Jamain, Xavier Olibo, Princess Beatrice, and Duke of Wellington. The remaining blooms were too much expanded. J. H. Pemberton, Esq., The Round House, Havering-atte-Bower, Romford, had the fourth prize, Beauty of Waltham being the best bloom; and an extra prize was awarded to Rev. E. L. Fellowes.

We now arrive at the last of the amateurs' classes, and certainly one of the best—namely, the class for twelve Tea-scented and Noisette Roses. Ten collections were staged, and a charming effect they produced. It is true that several blooms were more or less soiled and had their outer petals damaged, still, considering the earliness of the Rose season, the class was an excellent one. That good grower, John Hollingworth, Esq., won the first position with Devoniensis, Madame Willermoz, Perle de Lyon, Julie Mansais, Souvenir d'un Ami, Madame Margottin, Comte de Paris, Perle des Jardins, Niphetos, Cheshunt Hybrid, Madame Bravy, and Marie Van Houtte, all except the last named, which was injured, being in admirable condition. Mr. G. Rushmore, Tending Hall, Stoke, Colchester, had the second prize, Rubens in this stand being splendid, the remainder somewhat injured. G. Agate, Esq., Colney Hatch, Middlesex, was placed third with regular and good blooms but rather soiled; the fourth prize going to C. Davis, Esq., Grammar School, Aynhoe, Banbury. Perle des Jardins was charming in this stand; Bouquet d'Or, very pretty; and Ma Capucine, distinct by its deep coppery colour; Anna Ollivier exhibited by J. Mayo, Esq., Oxford, was unusually fine, perhaps the finest bloom in the whole class.

OPEN CLASSES.—Six collections were staged in the class for twelve Roses of 1876, 1877, and 1878. Messrs. Paul & Son, Cheshunt, won the first position with Magna Charta, Oxonian, Madame Emma All, Mons. Gabriel Tournier, Madame de Montchateau, all coarse; Marchioness of Exeter, Mrs. Baker, Emily Laxton, Mrs. Laxton, Marie Louise Pernet, and Mons. Fillan, a little better, but by no means good. Messrs. Curtis, Sandford, & Co. had the second prize. Jean Liabaud was very rich, and Magna Charta and Mrs. Baker were fairly good; but the rest—Marquise Adèle de Murinais, Madame Louise Marger, Lady Mary Keith, Madame Ferdinand Janin, Madame de Montchateau, and Madame Prosper Langier were all coarse and unattractive. The third and fourth prize collections of Mr. Piper, Uckfield, and Messrs. Keynes were similarly devoid of merit. The best blooms in Mr. Piper's stand were Triomphe de France, Abel Carrière, Rev. J. B. M. Camm, and Duchesse d'Ossuna; and the best bloom in the Salisbury stand was Mrs. Baker. Not a good class. In the class for six blooms of any variety of 1876, 1877, or 1878, Messrs. Paul and Son, Cheshunt, won first honours with Mrs. Laxton—neat, close, and symmetrical, but a trifle dull in colour, yet a promising Rose. Mr. Piper was second with Duchesse de Vallombrosa, and Messrs. Curtis, Sandford, & Co. fourth with Duchesse de Vallombrosa.

In the class for eighteen English-raised Roses in commerce Messrs. Paul & Son, Cheshunt, were the only exhibitors, staging good blooms, but more or less injured, of Marchioness of Exeter, John Hopper, Princess Beatrice, Miss Poole, Star of Waltham, Oxonian, Miss Ingram, Dr. Hooker, Beauty of Waltham, fine; Miss Hassard, Duke of Edinburgh, Emily Laxton, J. S. Mill, Devoniensis, Cheshunt Hybrid, Annie Laxton, Mrs. Laxton, and Magna Charta. They were awarded the first prize; and also for twelve English-raised Roses with an admirable stand of Sultan of Zanzibar, Charles Darwin, rather coarse; Oxonian, Prince Arthur, Miss Ingram, Robert Marnock, Annie Laxton, fine; Marchioness of Exeter, Mrs. Laxton and Emily Laxton, both very good; and Dr. Hogg, a medium-sized, symmetrical, and very richly coloured bloom, for which a first-class certificate was awarded. The foliage of this Rose was also fine and very round.

In the class for twelve trusses of La France Messrs. G. Paul and Son were first with magnificent blooms, and Messrs. Keynes second also with a splendid stand. Messrs. Keynes were also first with Marie Baumann with blooms of wonderful substance and much mottled; Messrs. G. Paul & Son second with smaller but excellent blooms of this good Rose. Mr. Cooling, Bath, won chief honours with twelve blooms of Maréchal Niel, one of which was magnificent; it was nearly 7 inches in diameter, of handsome shape and good colour. This was quite the premier bloom

of the Show. For twelve blooms of Etienne Levet Messrs. G. Paul & Son won the chief prize with an excellent stand.

MISCELLANEOUS.—Foremost to notice are the two fine new Roses of Messrs. Wm. Paul & Son, Waltham Cross—Countess of Rosebery and Duchess of Bedford. This stand almost created a sensation, the former Rose especially being generally admitted to be one of the most promising Roses of recent years. It is undoubtedly a Rose of sterling value, and may be popularly described as a greatly improved and much refined deep rosy or reddish-salmon Etienne Levet. It is smooth, symmetrical, of great substance, and has handsome foliage. Duchess of Bedford is a rich velvety Rose, crimson suffused with scarlet, petals elegantly reflexed and waxy. It is of the Beauty of Waltham type, and is very rich and glowing. The renowned Waltham Cross firm also staged a great and good general collection of nearly one hundred varieties containing blooms equal to the best in the classes, and were highly commended. Mr. Rumsey and Mr. Mayo had extra prizes for charming collections of Tea Roses; and Messrs. G. Paul and Son had a similar honour for one hundred Roses in pots extremely sturdy and dwarf, many of the fine blooms not being more than 6 inches from the surface of the pots; yet the plants were grown in a free untrained manner—i.e., the shoots had not been depressed. Mr. T. S. Ware exhibited an attractive collection of Pinks, Carnations, and Pansies; and Mr. Cannell staged a fine assortment of cut blooms of Pelargoniums and Verbenas; Mrs. Hodgkins of Manchester also exhibited a beautiful collection of skeletonised leaves.

Under the general superintendence of Mr. Trendall all who had duties to perform in connection with the Show had every facility afforded them for discharging those duties pleasurably.

NOTES AND GLEANINGS.

THE LONDON INTERNATIONAL HORTICULTURAL EXHIBITION is now definitely fixed for 1880. The International Committee (Sir D. Cooper, Bart., Chairman) appointed a short time since to make the necessary arrangements for holding the Show met Lord Aberdare and some members of the Councils of the Royal Horticultural and Royal Botanic Societies on Tuesday last in conference, when, in view of the present depression in trade, the counter-attraction of the Royal Agricultural Society's Show in 1879, and the fact of the Antwerp Show falling also in 1879, it was decided by a large majority that the London Show should be deferred till 1880, the Committee in the meanwhile to take such preliminary steps in reference to securing a suitable site as might seem desirable with a view to more energetic action in the ensuing spring. Mr. T. Moore, F.L.S., is Honorary Secretary for the Exhibition, and Dr. Masters, F.R.S., was appointed Honorary Secretary for the Congress, which it is proposed to hold, as before, in connection with the Show.

FURTHER contributions of FLOWERS are much needed. Those possessing gardens and conservatories who can spare a few bunches of cut flowers will confer a real benefit upon the sick and suffering poor by sending a hamperful occasionally. It is a great help when the flower holders that require it have wool attached for tying them to the bouquets; and it may perhaps also be well again to remind country readers that nearly all the leading railway companies will now forward hampers at a reduced rate of charge if they are plainly labelled "For the Bible Flower Mission." Friends will also kindly bear in mind that all parcels should be carriage paid and despatched so as to reach us by Tuesday forenoon. They should be addressed to Mrs. Barnardo, "Bible Flower Mission," Deaconess House, 1, Oliver's Terrace West, Bow Road, London.

AN INTERNATIONAL EXHIBITION OF ROSES is to be held in Antwerp on the 14th and 15th of July, organised by the Cercle de Roséristes d'Anvers. Schedules and programmes can be obtained of Mr. T. B. Lenaerts, 60, Rue des Fortifications, Antwerp, the President of the Society.

THE CHIPPING NORTON AMATEUR ROSE SOCIETY will hold its annual Exhibition on Friday, July 12th. A liberal schedule of prizes has been issued, and includes an open class for nurserymen and amateurs in addition to the local class, in which a handsome challenge cup will again test the prowess of the rosarians of the neighbourhood.

TROPEOLUM ALBIFLORUM has flowered very well with Mr. Dowdeswell this spring. It is an elegant plant. He is a great admirer of the Tropeolum tribe of plants, and is very anxious to recover a tuber of the T. Moritzianum, which he lost some years since and has not been able to meet with again.

STRAWBERRIES GROWN ON A ROOFTOP IN THE CITY

OF LONDON.—A correspondent has sent us a dozen Strawberries which were grown on the roof of a warehouse, in a thoroughfare within 100 yards of the General Post Office. The Strawberries are certainly of rich flavour, and possess an excellent aroma. Our correspondent thinks the growth of the fruit in such perfection is a proof of the comparative purity of the atmosphere; and we quite agree with him. He adds that he has a Cherry tree on the same roof, with fruit on, which promises to ripen. To these interesting facts in connection with City pomology we may add that some fine specimens of Figs, likewise grown in the City, were sent to us some time ago; and that another correspondent used regularly to send us some excellent Grapes, grown near the London Institution in Finsbury Circus.—(City Press.)

A CORRESPONDENT, "S. N.," writing to us on GENTIANA ACAULIS, states that he has grown it for many years; first in the neighbourhood of Lancaster, at the edge of a border by a gravelled walk. He then removed the plants into Gloucestershire in February; they flowered twice in the following and succeeding year. They were brought to the neighbourhood of Chester in November, 1876, and flowered sparingly in a bed the following summer. In February this year they were again removed, but in the same garden, to the edge of a bed bounded by a gravelled walk, where they flowered very well early in May. They are now looking most healthy. All our correspondent has seen grown in the north were grown as he has grown them, and were luxuriant.

THE largest STRAWBERRY FARM in the world is about two miles from Norfolk, Va. It contains 200 acres.

ALLUDING to the ARUM AS AN INSECTIVOROUS PLANT "E. W. B., Mossley," writes as follows in the "Midland Naturalist":—"For two years past I have grown a plant of Arum crinitum in my garden, and each year it has produced one of its lugubrious-looking spathes. When the inflorescence is fully developed a most offensive carrion-like smell is emitted. Directly the disagreeable odour is produced bluebottle flies (Musca vomitoria) make their appearance and swarm on to the protruding lip of the spathe. Both years I have noticed no sign of these flies until the fetid smell of the Arum attracted them. The flies seem strangely and powerfully fascinated by the Arum. They fly unerringly to the plant; they then speedily make their way to the narrow entrance to the lower part of the spathe in which the base of the spadix is chambered in almost absolute darkness. The inlet is narrow, and is well protected by hairs, though they seem no obstacle to the ingress of the flies; but after they are once inside there they must remain, whether stupefied by the noxious exhalation of the plant or imprisoned by the hairs which yielded them such easy entrance I do not know. I have watched the plant for hours, but never saw a fly return from what may be deemed a condemned cell. The spathe remains open only a day or two at most, and then gradually closes and shrivels up. Each year at an interval of a week or so after the closing of the spathe I have cut open the chambered part of it and have found it nearly full of dead and partially decomposed flies."

PROFIT OF GRAPE-GROWING.—Mr. E. F. Ellwanger, says the "American Gardeners' Monthly," makes the good point that those who find Grape-growing "don't pay" are generally those who have gone into it from some other business, and who thought plants ought to "grow into money while they slept." Honest profit means honest labour; "No work no pay" is Nature's law in gardening. Mr. Ellwanger thinks that the man who first loves his trade and then sticks to it generally succeeds, and we quite agree with him.

THE New York Medical Record (May 18th) states that the NEW YORK FLOWER AND FRUIT MISSION recommenced its operations for this year on May 1st, and distributions will take place every Monday and Thursday to the different hospitals, asylums, prisons, and other public institutions, and also to the sick and destitute in the tenement houses of the city. The ladies having the work in charge anticipated but a comparatively small supply of flowers the first day; but, instead of this, there was a sufficient number sent in to make more than four thousand bouquets. Of these, four hundred, composed exclusively of Lilacs, were sent to the blind asylum, as the blind seem to be more fond of the odour of Lilac than almost of any other shrub or flower. The Flower and Fruit Mission accomplishes its work at probably a less cost than any charitable society that ever existed in New York, for during the eight years of its existence its

actual expenses have amounted only to \$125. The flowers and fruit are all given by friends of the charity; the railroads, as a rule, furnish free transport to those sent from the country; and the ladies who distribute them pay their own expenses to and from the institutions visited by them. These kind-hearted ladies make no parade of their doings, and no names are even made public, except that of the lady secretary for business purposes.—(*The Week*.)

ALYSSUM WIERZBICKII.

THIS plant belongs to a small genus of Crucifers, one species, *A. saxatile*, being as familiar to gardeners as household words. We fear, however, this will not be the case with the name of the species of which we now give an illustration. Unpronounceable though the name would appear, the plant is de-

Fig. 72.—*Alyssum Wierzbickii*.

serving the attention of everyone having even a small garden. It is an erect grower, attaining a height of about 2 feet, but commences flowering when a foot or 15 inches; the additional height arising from the growth of the flower spike, which, it will be readily understood, materially lengthens the period of its beauty. Our figure was taken from a plant kindly furnished by the Messrs. Rollisson & Sons of Tooting, in whose nursery a bed of this has been in full beauty since March, and even now as we write it is not quite past. The plant is an erect grower, producing oblong lanceolate rugose leaves, light green on both surfaces. The stem also is the same shade of green, rugose and hirsute. Flowers numerous and bright yellow.

It should be sown at once for blooming next spring, whilst those just going out of bloom should be cut down; but we would not advise the plants to be kept longer than the third year, as they get woody and unsightly at bottom, and do not produce such fine spikes of flower as the young seedlings. It may also be increased from cuttings if desired. These plants

may be grown in almost any soil, but a calcareous loam suits them best.

GRAPE VINES FOR TEXAS.

YOUR correspondent, "J. H. W.," wishes for information with regard to which Vines it would be desirable for him to take out with him to Texas.

The European varieties of the Vine do not generally succeed well in the United States except under glass, the changes of temperature in a short time are so great; therefore, if I intended to settle there I should only take a few of the hardiest, such as Buckland Sweetwater, Black Hamburg, Royal Muscadine, and some of the Muscates. The Muscat of Alexandria would be as likely to succeed as any, and Pearson's Golden Queen might be worth a trial. Texas is a large country, and I do not know what part of it "J. H. W." is going to, or whether the situation is elevated; but if not, and his intention is to go to considerable expense in starting a vineyard, I should certainly advise caution, and recommend a little experimenting first, for it would be almost certain to end in disappointment and vexation. The only Vines which would have a chance of succeeding would be the American varieties, such as the Isabella and Catawba, and they would be uncertain so far south as Texas, which is beyond the regions of the Wheat and Indian Corn, which are the natural home of the Grape Vine.—AMATEUR, *Cirencester*.

CALIFORNIAN DICENTRA.

IN my botanical researches in California I have found few flowers which were discovered with as much pleasure as our various *Dicentra*. I well recollect the first time I found the variety known as *D. formosa*. At that time I did not know we were so highly favoured as to have any members of the family within our borders. It was in a little grassy vale. When I saw it, so much did it resemble *D. spectabilis* that I thought it was a stray plant of that well-known Chinese variety, the Bleeding Heart of our gardens. On a slight examination, however, I soon saw my error, but so highly pleased was I with it that I dug it and removed it to my garden.

The *Dicentra* belongs to the natural order *Fumariaceae*. In California we have three varieties that I am acquainted with.

Dicentra formosa in the Sierra Nevada, at an altitude of 6000 to 8000 feet, is found in grassy vales near streams of water. It grows from 1 to 2 feet high. The flowers are borne on a compound racemose scape, from which they hang pendent. The flowers are of a rosy purple colour; the centre is a bright cream colour; thus forming one of the grandest combinations among flowers.

D. chrysanthra is the most robust and vigorous of our native varieties, often growing 4 to 5 feet high. The leaves are immense, often 15 inches long. The flowers are borne on long racemes, from which often branch out shorter scapes. The flowers are large, one-half to an inch in length being the average size. They are of the most brilliant yellow colour, and when the sun shines they sparkle and glisten as though freshly varnished. This variety, while it lacks much of the graceful habit of the other varieties, surpasses them in brilliancy and show. In their natural haunts they grow in a moderately light soil in the vicinity of running streams. In cultivating them it will be best to plant in similar places if possible. The finest flowers I have always found on plants growing in the shade of trees.—(*American Gardener's Monthly*.)

CHOICE GARDEN ORCHIDS.—No. 2.

ÆRIDES, Lour.

A. Fieldingii, Lindl. (fig. 73).—This species is, perhaps, one of the finest and most distinct in the genus, yet it has not found sufficient favour amongst botanical artists to have been previously figured. When first introduced it was known by the popular title of the Fox-brush *Ærides*, from the long dense raceme of flowers which it produces. Leaves strap-shaped, thick and leathery in texture, channelled above, unequally notched at the apex, and very deep green in colour. Raceme dense, 1 to 3 feet long, branching, pendulous. Flowers large and open. Sepals and petals oblong obtuse, the lower pair much the largest. Lip flat; middle lobe large, ovate acuminate. Colour rosy lilac, with a streak of reddish crimson at the base. May, June, and July. Assam. 1851.

A. Fieldingii, Lindl.; var. *Williamsii*, Hort. Syn., *A. Williamsii*, Hort. (Warner's Select Orchids, 1, p. xxi.).—This

handsome variety may be readily distinguished even when not in flower by its very robust habit of growth. Leaves 12 to 15 inches in length, very broad, strap-shaped, channelled above, notched at the apex, leathery in texture, and deep green. Racemes pendulous, dense, 2 to 3 feet long. Flowers as large as the species. Sepals and petals oblong obtuse, pure white. Lip flat, ovate acuminate, white, tinged towards the base with rosy pink. May and June. Assam.

A. crispum, Lindl. (Bot. Mag., t. 4427).—A handsome free-

growing and very ornamental species. Stem blackish purple. Leaves somewhat distant, 6 to 8 inches long, broad, flat, obtuse, and bilobed at the apex, deep green. Racemes ascending, 12 to 18 inches long, many-flowered. Flowers large and of great substance. Sepals and petals ovate, acute, waxy-white, tipped with deep rose. Lip three-lobed; middle lobe large, toothed at the base, and slightly fringed in front. Colour rich rose. Spur short, incurved. May and June. Bombay. 1840.

A. crispum, Lindl.; var. *Warnerianum*, Hort. Syn., *A.*

Fig. 73.—*AERIDES FIELDINGII*.

Warnerii, Hort.—This is a very slender-growing plant compared with the normal form; indeed it may yet prove entirely distinct from *A. crispum*. Stem dark purple. Leaves short, narrow, and ascending. Raceme nearly erect, much longer than the leaves, many-flowered. Sepals and petals pure white. Lip large, rich deep rose colour. June and July. Bombay.

A. Schraderii, Hort. (Gard. Mag., 1850, 11, p. 121). Syn., *Aërides maculosum Schraderii*, Hort.—A truly magnificent plant, by some considered to be a distinct species, by others a natural hybrid between *A. crispum* and *A. maculosum*, and again by some a variety only of the last-named species. We ourselves have held all these opinions, but have gradually been

compelled to acknowledge its total distinctiveness. In habit it is robust and free-growing, producing broad leaves some 10 inches long, arranged in a distichous manner, unequally lobed at the apex, and bright green on both sides. Racemes much branched, bearing from twenty to sixty of its large and handsome flowers. Sepals and petals broad, oblong obtuse, creamy white, tinged and streaked with rose. Lip flat, three-lobed, with the small teeth at its base incurved, and the intervening tubercle bifid; middle lobe very large and deep rosy crimson in colour. June and July. Bombay. Only one plant has ever been imported. 1849.

A. maculosum (Bot. Reg., xxxi, t. 58).—This is a very slow-

growing plant, and somewhat more difficult to cultivate than the majority of the species belonging to this genus. We believe it requires less heat, less water, and more air than is usually accorded it, and on account of its bad treatment it is less seldom seen in bloom than it otherwise would be. Leaves ligulate, some 9 inches long, obtuse at the apex, thick and coriaceous in texture, closely set on the stem, and dark green in colour. Raceme pendulous, double the length of the leaves, many-flowered. Sepals and petals broadly obtuse; ground colour soft rose spotted with purple. Lip large, flat, and undivided, bluntly ovate, and rich purplish rose in colour. June and July. Bombay. 1844.

A. falcatum, Lindl. Syn., *A. Larpenta*, Hort.—A free-growing plant of great beauty. Leaves short, coriaceous in texture, obtuse and mucronate at the apex, imbricating at the base, and of a peculiar blue-green colour throughout. Racemes longer than the leaves, pendulous, many-flowered. Flowers large. Sepals and petals broadly obtuse, tipped with rose or rosy purple; ground colour white, freckled with reddish crimson dots. Lip large. Side lobes white; middle lobe deep rose. Spur short, parallel with the lip. May and June. East Indies. 1846.

A. odoratum, Lour. (Bot. Mag., t. 4139). Syn., *A. cornutum*, Roxb.—A robust-growing plant, and the commonest species of the genus in cultivation. Leaves distichous, flaccid, oblique, obtuse, mucronate at the apex, and dark green. Racemes pendulous, dense, many-flowered, usually longer than the leaves. Flowers very fragrant, creamy white. Sepals and petals pink at the tips, fleshy, roundish-ovate. Lip cucullate, funnel-shaped. Lateral lobes erect, cuneate, rounded; middle lobe ovate, acute, inflexed. Spur conical, incurved. May, June, and July. East Indies. Widely distributed. 1800.

A. odoratum, Lour.; var., *majus*, Hort.—A variety which cannot be distinguished from the normal form when out of flower. The racemes are much longer than in the type. The individual flowers are much larger and the colour deeper, rendering it a most desirable form.

A. odoratum, Lour.; var., *longiracemosum*, Linden.—This plant is more lax in its habit of growth than any other variation of the species, and, as its name denotes, it produces very long racemes of flower, which resemble the normal form both in size and colour. Upper Assam.

A. odoratum, Lour.; var., *purpurascens*, Hort.—A very robust-growing plant, producing broad, stout, deep green leaves which are shorter than the type, and by this character alone it may be distinguished. The racemes are much longer than the leaves. Flowers large and numerous, forming a very dense spike. Colour deeper than the species.

ROSES AT SOUTH KENSINGTON.—JUNE 17TH.

As your reporter has justly observed, although the Society placed the Roses in the forefront the Pelargoniums formed the larger portion of the Show, but not the most attractive portion. The crowds that surrounded the boxes of the queen of flowers sufficiently testified to her popularity, and a few notes from an "old hand" may not be unacceptable. It was a pleasure to see our old friends re-appearing, to hail the stands from Hereford, Monkton Wyld, Salisbury, Cheshunt, and other places; but most of all pleasing to me was to see my veteran neighbour, honest John Hollingworth, coming out as he has been wont to do, and taking first prizes in each class in which he exhibited. "I am getting old, and the old love is dying out," were his words to me some time ago. Not a bit of it; as long as he can he will be found doing his very best, and I hope we may long see him entering the lists.

Who was there who knew aught of Roses that was not astonished at the size of the blooms exhibited from the nursery at Salisbury, until lately under the loving care of John Keynes, and let us hope under its new arrangements to keep up its well-earned reputation? I may be mistaken, but it seems to me that this is an index of coming events. I cannot but fancy that this year will be a grand one for such soils as that of the Salisbury nursery (light and warm), and that the really Rose soils, the heavy loams, will not do so well. The light-land farms will do best this year, and so, it may be, it will be in Roses. There has been too much wet perhaps for the heavy soils, but the light ones rejoice in it. Personally I have not had for years such flowers as this season, and my soil is light. We have a saying in Kent—

"When England wrings (i.e., her hands)
Thanet sings,"

the light chalk lands of the Isle of Thanet bearing any amount

of rain. There was one bloom of Général Jacqueminot from Salisbury, which for size and colour was indeed a sight; grand, too, were the blooms of La France, Marquise de Castellane, and Marie Baumann. In Messrs. Paul & Son's stand there was a magnificent bloom of Mrs. Laxton, fully bearing out the opinion I formed of it at Manchester; it is a grand Rose of exquisite form, plenty of stuff in it, and of large size, of the Alfred Colomb type. It appeared again in Messrs. Paul and Son's new Roses, and will, unless I am mistaken, be found one of our very best exhibition Roses. Very good, too, in this class was Sultan of Zanzibar, one of the deep-coloured class which Cheshunt has sent forth, as Reynolds Hole, Duke of Connaught, &c. In the second box in this class it would have required as microscopic an eye as Lord Salisbury said was required to detect the difference between the proposal of England and the terms of Russia, to say wherein lay the difference between Mons. G. Tournier and Madame W. Bull. Mr. Hollingworth's box of Teas was lovely, but is it not a mistake to put Cheshunt Hybrid amongst them? It is indeed a colour much wanted, and although it has Tea blood in it yet it is not a Tea, and moreover it is out of keeping with the others, its shape is different, and its size too great generally; it is a most useful Rose, a grand fellow for the garden, but he is hardly a fitting companion for the dainty dames by whom he was surrounded. In Mr. Wyatt's collection, and indeed in very many of the stands, Mons. E. Y. Teas was in grand form. This is likely to prove one of the best additions of late years. Our old friend Charles Lefebvre came out grandly, and he might well ask what the saucy dame Marguerite Brassac meant by assuming to herself such airs, for the two were exactly alike; but I fancy the latter is a better grower. Belle Lyonnaise in both Mr. Camm's and Mr. Jowitt's boxes was good, and were it not for the defect that it has of coming with a cleft centre would be one of the very grandest of yellow Roses.

A great deal is said about the sad uniformity of a Rose show, and attempts to break through are frequently insisted on and sometimes made, but they never are carried out without manifest disadvantage and no improvement. Mr. Wills's attempt at the Aquarium was a failure, and if that were the idea at South Kensington I think everyone must be convinced that it was equally a failure there. The boxes were put up and down anywhere amongst the plants on the slopes, and the result was great confusion and difficulty in getting at the entries.

I look hopefully on to our grand tournament on Saturday next. This tropical weather must surely stop anyone from writing "My Roses are too backward," at least if I may judge from my own. As I do not exhibit I do not shade, and the rapid manner in which they are coming into bloom is astonishing. Dark Roses, too, like Baron Bonstetten, La Rosière, &c., are literally burnt up before they can expand. Exhibitors are sending in their entries in great force. Ireland will furnish a contingent, and I hope every district will be well represented, and that all will go "merry as a marriage bell."—D., Deal.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 20.

In this series of articles some account has been already given of the garden ground, now mostly built upon, situate in South Lambeth, Vauxhall, and Stockwell; Vauxhall, astonishing as it may now appear, having once been famous for its flowers, especially for its Camellias, and Stockwell being noteworthy as a place that was once to have been the selected spot for a Botanic garden that was to be both popular and instructive. The scheme collapsed, however, as schemes both good and bad are apt to do, and at present the south Londoners cannot be said to be particularly favoured with the means of acquiring botanical knowledge. A solitary nursery, the survivor of several that formerly existed in or near the South Lambeth Road, has, I perceive, succumbed to the builders within the last few months; it was just beyond the bend in the road near the distillery, and overshadowed by a pretentious structure denominated a "Board School," recently erected. Perhaps the unlucky nurseryman found that the scholars stole too many Roses and Geraniums, and exercised too much dexterity in the smashing of glass! We may hope that in another generation, however, every school will have a plot of ground as large attached to it, where the pupils of either sex can make acquaintance with growing plants placed under some classification, and learn especially the names of those species that are natives of these islands.

Continuing our survey of Surrey we will now pass from the

places referred to in order to notice the adjacent districts of Camberwell and Brixton, both of which have been subject to a surprisingly rapid increase of buildings during the last twenty years or so, in consequence of which parks, fields, and nurseries have had to lose their rural or floral beauties and surrender their ground to lines of streets or terraces. One peculiar feature of this portion of Surrey are its hills, which form a singular natural rampart, rising and falling at intervals, while at each end they slope off into the Thames valley. Leaving out of the view the many hills of Norwood we may remember the following:—"Plew-garlic" Hill, Nunhead Hill, Grove and Champion Hills, Denmark and Herne Hills, Brixton Rise, Clapham Rise, Battersea Rise. From amongst these in former times rose many little springs, which contributed much to the fertility of the district. Moreover, it had once its stream, or a river seemingly, for monarchs passed up it under the shade of Alders and Willows when inclined to wander in the Surrey woods. The last, it is reported, who did this was Queen Elizabeth, and for many years the stone to which her barge was moored was preserved as a relic. Rising in Norwood the Effra, as it was called, flowed through Brixton, passing close to the church of St. Mark's, Kennington, finishing its course by entering the Thames near Vauxhall. Now covered in and converted into a sewer, it has shared the fate of the Fleet river and other London streams; but it has had a recent opportunity of taking revenge for this ill usage. On the 11th of April of this year, in consequence of the enormous rainfall, the Effra received so much water during a few hours that the immense pressure forced up the arch of the brickwork covering it along the line of the Brixton Road, scattering gravel in all directions and shifting large slabs of pavement. Not only was the road flooded, but the basements of houses suffered considerably.

Proceeding to Camberwell (which, for no sufficient reason, a modern topographer calls Camerwell, an old name certainly, yet Camberwell or Cambrewell dates from the Conquest), evidently designated from one of the Surrey springs. It is to be observed that at a period when there were numerous nurserymen in Middlesex there were none in Camberwell, and not many market gardeners. Nurseries grew up about the London suburbs in proportion to the requirements of the dwellers, and the thinly populated "Surrey side" of the Thames offered few inducements to the enterprise of nurserymen till the accession of George IV., or about fifty years ago. The produce of market gardens could, of course, be taken to metropolitan centres by land or by water. In 1766 Camberwell parish, an extensive one, contained scarcely eight hundred houses, but so rapid was its growth between 1820 and 1840 that in the latter year there were upwards of eight thousand, and, like every suburb, it has grown still more populous since that time. Though marshy at one period it always had the repute of being healthy, hence many detached residences were erected on or near the main road, some with park-like grounds attached to them. When Lysons wrote his account of the "Environs of London" in 1792 the open land was, he states, nearly in equal proportions—arable, pasture, and garden; but on a large part of this garden ground crops were grown to supply food to the cows, which were numerous in Camberwell. There do not appear to have been many orchards in the vicinity, though an "Orchard Row," near the Green, records that there was once an orchard there, and an orchard is specified in connection with the estate of one of the Camberwell manors, long held by the Bowyer family. Revising his book in 1811 Lysons had to report that the cowkeepers had diminished in number, but he considered about 200 acres of land belonged to the market gardeners, nearly the whole of the ground in proximity to Camberwell New Road being then under cultivation; there was also much produce raised near the Surrey Canal, between St. George's Church and Peckham New Town, on land now covered by buildings called Grosvenor Park, and various streets. Coldharbour Lane—originally named, it is presumed, from Cold Abbey, one of the Camberwell manors—was, in the memory of persons not very venerable, only a lane intersecting market gardens and joining Camberwell to Brixton. The railway lines crossing the district have done much in the way of spoiling the garden grounds, especially those belonging to the London, Chatham, and Dover Railway Company. Some of the land lying between the Camberwell New Road station and Holland Road, on which vegetables are still grown, represents, as I conclude, the older market gardens hereabout, and it is noticeable that, owing to the difficulty of guarding against depredations in these populous

suburbs, gardeners prefer to cultivate what is less likely to be stolen. Rhubarb, Cabbages, and Potatoes do not offer strong temptations, but even the last, although digging is requisite, are sometimes carried off by the thievishly inclined. Messrs. Martin, Myatt, and Goshawk are the principal market gardeners now at work in this part of Camberwell. There are several nurserymen and so-called "florists;" amongst these the pre-eminence may be justly assigned to Mr. Fryer of the Camberwell New Road, where his principal establishment is situate, and where, despite the London smoke, many plants flourish in the open air as well as under glass. The extent of the land at present occupied by him in this spot is small, and it is encroached upon by houses on all sides. It furnishes an illustration of the manner in which garden ground has been subdivided, in consequence of the difficulty there has been of late years in retaining plots of some extent, when we state that Mr. Fryer has also ground in three or four other places in the neighbourhood. It is true that advantages may arise from this, as it enables a nurseryman to secure patrons in different localities when business is done at these branches. The "Clarendon Nursery," for so is Mr. Fryer's named, was established early in this century by Messrs. Buchanan, Oldroyd, and Marsden, and for the last forty-five years it has been in the hands of the present energetic proprietor.

Brixton, now no longer in the country yet retaining a semi-rural aspect, is the greater part of it, an outlying portion of the parish of Lambeth, a fact of which ratepayers in Brixton are unpleasantly reminded. Originally, so say antiquarians, it was Brixiston, probably from Brixi's or Brice's Stone, some old landmark there. It had its corn fields not so many years ago, and towards Brixton Rise there remained until quite recently a portion of the old forest of Sherwood, which, given by William I. to the Londoners, was by them allowed somehow to slip out of their possession. One of the more important estates was in or about 1740 bought by Lord Holland; it was presumed to have taken its name from Henry Hastings, Lord Loughborough. There were at that time orchards of some extent, and about 234 acres of land altogether; part of it was so very marshy at certain seasons that the road across was called the "Washway." This land was gradually improved in condition for gardening purposes, and before the extensive building operations commenced which have transformed the district, the Loughborough Nurseries were rather famous. Mr. Denyer, nurseryman and market gardener, who had been under Mitchelson of Kennington Oval, is the oldest on record there; the office of his establishment was in the Loughborough Road. His successor was Mr. E. Randall, whose grounds underwent the process of gradual diminution to which London market gardens are so subject. The "Swiss Nursery," occupying (it I am not mistaken) land adjacent to that held by Messrs. Denyer and Randal, had its stock dispersed in 1877. The only establishment now remaining, and which, without intending any invidious comparison, may be styled the leading one in Brixton, belongs to Messrs. Ponsford & Son of Loughborough Park. This nursery was commenced in 1843 by Mr. Samuel Ponsford; about four acres is the present extent. Much of the cultivation is done under glass, and a large amount of general nursery stock is kept on hand for the supplying squares and gardens. Branches exist in the Brixton Road and at Denmark Hill. For many years past the Mulberry has been one speciality with the firm, from 1500 to 2000 plants being taken from the stools every year and sent amongst the trade or the general public. (It is curious that centuries ago the Mulberries of south London were famous—thus, there was Queen Elizabeth's tree, amongst others, growing in the gardens of Carlisle House, Lambeth. Oldys, when he saw it in 1753, noted that "it had been split by the weight of its own shade and fruit," and he guessed that the shadow extended over a circumference of 40 yards. The tree yielded that year, old as it was, nearly five hundred pottles of fruit.) As Messrs. Ponsford & Son have a good term of lease before them we may hope that their nursery will not have to disappear before the expanding metropolis; fortunately horticulture here is not greatly affected by the smoke of London. From thirty to fifty persons are employed by the firm according to the season.

There are several nurserymen in the Brixton Road, upon whose establishments, which have scarcely any land attached to them, it is not needful to make remarks. There is one, however, owned by Messrs. Lane, Brothers, which represents the Angell Town Nursery, occupying a part of the gardens, now nearly built over, belonging to the eccentric John Angell, who,

dying in 1784, left his property to found a college on peculiar conditions, but the Court of Chancery set aside his will. Acre Lane had once fields and market gardens on both sides, but houses are being rapidly erected there, and an "estate" has been just cleared for building purposes which was under cultivation a few months since.—C.

A GLIMPSE AT THE ALEXANDRA PALACE ROSE SHOW.

THE Show was not a large one. It is likely to be a late season. Several well-known prizetakers were conspicuous by their absence; but the Roses shown, like the British Infantry, if few by comparison were mostly excellent in quality. Not venturing to discuss the prizetakers, the chief other objects of attraction were certainly Mr. W. Paul's new seedlings. I believe Countess of Rosebery and Duchess of Bedford are not yet in commerce; whenever they are we may reckon on a considerable run on them. Both are of the reds; the latter rather dark, admirable in shape, vivid in colour, especially the Countess, and altogether the most striking novelties I have seen lately. Another seedling of Mr. W. Paul, which he has called May Quennel, also appeared to be a Rose of very considerable promise. Much admiration was also freely expressed for twelve wonderful La Frances hailing from Cheshunt. How Mr. George Paul can bring them to such a size without coarseness or loss of colour can only be intelligible to those who have seen the Old Nurseries. The show of Tea Roses was fine, Turkey Court, Maidstone, again taking the lead amongst the amateurs, and the Mitchells of Pittdown being as so often first of the nurserymen. It will be interesting to observe how the Manettis do this wet season. My impression is that Briar stocks will outdo them. I expected great things from a carefully made new bed last autumn of a hundred Manettis, and now find the plants looking remarkably miserable.

There appear a great variety of Rose prophets this season and very considerable disappointment exists in some quarters. The general impression, however, is that the National Rose Society have selected their days with very extreme discrimination.

June 22nd, "*Probitas laudatur et alget.*" Let us hope that the British public will not only praise but liberally support a Society which is catering for them with such successful diligence.—A. C.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THOUGH the time has not yet arrived for sowing the Tripoli section of Onion and that most useful vegetable Winter Spinach, it is well to consider them beforehand, so that due regard may be had to the reservation of ground and its preparation for these important crops. The Onion will succeed spring-planted Cauliflower, which will be off in time for the Onions. We prefer this rotation to any other; the ground having previously been trenched and manured for the Cauliflower will be in fine trim for sowing the Onions, requiring only to be forked over. Spinach will do well after Peas, Beans, or Potatoes. Peas of the earliest kinds will by this time or soon be over. A clearance should be made at once, the ground forked over and at once planted with Cauliflower, Broccoli, or such winter greens as are most in request. Similar remarks apply to ground from which early Potatoes have been lifted, planting without delay any greens likely to be useful in autumn, winter, or spring. Make a sowing of French Beans in a warm situation, and a moderate sowing of Turnips, Lettuce, Radishes, and Spinach, so as to maintain the succession. Take up Shallots as soon as they indicate ripeness, and after drying store them away in bunches or otherwise. Plant out Leeks in well-manured trenches; those in beds thin from 9 to 12 inches apart. Sow Parsley, some in a warm sunny situation, and subsequently thin the plants to a foot distance apart. That sown previously should be thinned to that distance, planting out some at the base of a wall, where it can readily be protected in severe weather. It must be well watered until established. Make a sowing of Peas of the early varieties, and in warm situations a sowing of Ne Plus Ultra, which if the autumn be favourable will give a good supply of produce certain to be esteemed. A sowing of Early Longpod Beans should also be made, late crops being as highly appreciated as the earliest. Ridge and Gherkin Cucumbers may yet be planted, placing about a barrowful of loam and a little well-decayed manure in a heap, and plant two plants on each; or, if Vegetable Marrows are wanted, one. Capsicums plant out in rich light soil in a warm situation, in rows 18 inches asunder and 12 inches apart. Strong plants showing fruit only should be put out. Basil, Marjoram, and Summer Savory should be thinned to

6 inches distance apart in the rows, also Thyme and other herbs sown in spring.

HARDY FRUIT GARDEN.

The sap not being required for the swelling of the fruit (which in most instances is not more plentiful than it was last season) is imparting considerable vigour to the young shoots, they, unless checked, promising to be unduly vigorous—gross in fact, and unfruitful. To induce the formation of fruitful wood early stopping must be resorted to, allowing time for the formation of fruit buds by the exposure of the foliage producing them fully to light and air, the thorough ripening of the wood, and as great freedom as possible from insects, which the removal of the useless spray effects to a considerable extent. Prior to stopping the growths the requisite shoots for filling-in vacant space must be secured, and then all spray can speedily be disposed of by the secateurs. After pruning, if there be any aphids, syringe thoroughly with the garden engine, employing tobacco juice diluted with six times the quantity of rain water. All side shoots and forerights should be cut back to three leaves. This will cause spurs or fruit buds to be formed at the base of such trees as the Apricot, Plum, and Cherry, and by admitting light and air to the spurs of Pears the buds will be plumped, the energies of the trees being expended upon them instead of in the formation of gross useless growths. The late prolonged cold dull weather has not been without its effect upon Peach and Nectarine trees: blistered leaves, owing to their tissues being injured, are plentiful, and aphids has become troublesome. The former should be removed at once, as they only draw the sap from the other parts, and the shoots infested with green fly should be dipped in tobacco water. In laying in the shoots of Peaches and Nectarines, also Morello Cherries, small twigs of Privet or Birch are useful in saving time and labour, the ends of the twigs being readily thrust under the older branches, and where the walls are wired this mode of securing the shoots for the summer is preferable to tying. Strawberries promise abundantly; the weather has been all that could be desired, the rains having encouraged surface roots, which, in case of a dry time setting in, recourse must be had to artificial waterings, which more particularly applies to shallow soils. Attend to trussing up with a view to fine clean fruit for dessert. The scions of trees grafted in spring must have the ligatures loosened or removed, or the rapidly swelling shoots will be injured. The grafts must be secured to sticks made fast to the branches on which they are worked, or they will be liable to be blown off. Shoots from the stock must be rubbed off as they appear.

FRUIT HOUSES.

Peaches and Nectarines.—In the earliest house the fruit will all be gathered and most of that in the next early house, that in the third house taking its last swell for ripening. When the fruit is all gathered attend to syringing the trees morning and evening with a view to dislodge red spider, employing a garden engine, which is much more effectual than the syringe; and in case of the syringing not effecting a clearance apply a solution of soft soap, 3 ozs. to the gallon of water, wetting every part of the trees well, especially the under sides of the leaves. The border, if at all dry, should have a good watering—sufficient to reach the roots; and in case of weakly trees weak liquid manure will materially assist them in forming plump flower buds. With a view to prolonging the season fire heat may be discontinued in houses where the fruit is ripening, and air should be admitted freely day and night, maintaining a good moisture at the roots to compensate for the lessened moisture in the atmosphere consequent upon the fruit ripening. In houses where the fruit is taking the second swelling after stoning apply the syringe vigorously to keep red spider under, as if it get a hold before the fruit commences ripening it will seriously affect the quality of the fruit and impair the foliage for the perfecting of the buds for future bearing. Keep the borders well mulched and thoroughly watered, giving a sprinkling of guano over the surface of the border to weakly trees, and wash it well in. Afford plenty of air whenever the weather is favourable, and close early in the afternoon to economise heat. Dispense with fire heat (only in the case of fruit ripening fire heat may be necessary) to admit of air being given with a view to highly flavoured fruit. When the fruit is ripening 65° to 60° at night, 70° to 75° by day, and free ventilation will afford well-swelled good-flavoured fruit, having a rise of 10° to 15° from sun heat, the atmosphere being kept dry. Keep the shoots well tied down. Laterals on the strong shoots pinch back to the lowest leaf, and thin out superfluous shoots. In the latest house admit air freely, employing no fire heat, only in a dull cold period the heat may be turned on in the early part of the day for a few hours to admit of a free circulation of air. Mulch both the inside and outside borders with short manure and water abundantly, finally thinning the fruit, keeping red spider under by syringing twice daily, and if it obtain a footing promptly apply an insecticide.

Vines.—Grapes to hang over the winter months require more thinning than those not intended to keep for any lengthened period. The high and dry borders of modern culture do not receive, as a rule, anything like the quantity of water they require, especially inside borders. They should be well mulched and very

liberally watered, sprinkling them with guano in the case of weakly Vines, and washing it well in. This more particularly applies to those swelling off the fruit, keeping them free of all gross lateral growths. To those colouring give plenty of air with abundance of heat, as nothing contributes so much to high flavour and finish as a free circulation of rather dry warm air; but Vines struggling with a heavy load of fruit should not be subjected to so high a temperature as those luxuriant and carrying no more than a fair crop, but rest must be afforded them at night by allowing the temperature to fall to 60°. Old Vines from which the Grapes have been cut should be kept free from insects, for if the foliage fall a prey to red spider it is not unlikely a second growth may set in when they ought to go to rest; therefore syringe the Vines every evening so as to preserve the old foliage as long as possible. Afford frequent surface waterings to young Vines with the object of keeping the roots near the surface, applying it at a temperature of 90° to 100°, well mulching the surface of the border.

Orchard House.—The fruit of Apricots, Peaches, Nectarines, Plums, and Pears will have been thinned to the requisite number intended for the crop; if not it should not longer be delayed, as the fruit will now be swelling rapidly and require encouragement. Mulchings of rich material should be given the surface of the pots or borders, affording liberal supplies of water. Trees in pots carrying a heavy crop of fruit should have liquid manure in addition to the mulchings two or three times a week, and any weakly trees should have the fruit more severely thinned than those that are very vigorous. Maintain a genial atmosphere by copious syringings every morning and evening whenever the weather is warm, which is equally necessary to keep down insects and to maintain an atmosphere favourable to growth. When the external air is cold it is desirable to close the ventilators rather early in the afternoon and during high winds, which rushing through the house promote excessive evaporation and cold, not at all conducive to the health of the inmates. Go over the trees frequently, pinching back or disbudding strong shoots, which, if unrestrained, spoil the form of the trees and appropriate sap to the detriment of the weaker parts and fruit; but avoid removing an excess of foliage at any one time, as great denudations of foliage induce gum and canker, soon causing the trees to become unhealthy. Cherries will be fast approaching ripening, in which case syringing must be discontinued; but if there be any black aphid it must be got rid of by fumigation, which, if the trees are in pots, is best effected by placing them in a separate structure, and if they could remain in such until the fruit is gathered all the better, as they could then be kept cool and dry, keeping the fruit in season as long as possible. If a structure is not available the trees should be placed by themselves in some part of the house, scrutinising the shoots for black aphid, washing any part infested therewith with tobacco water, or dust the infested shoots well with tobacco powder, washing thoroughly the following morning with the syringe or engine. Nets will need to be placed over the ventilators to exclude birds. In some, indeed most orchard houses, space is allotted for a Vine or two. In span-roofed houses there can be no objection to them, training a single rod along the ends and under the ridge of the house over the pathways, having wires fixed at about 14 to 16 inches from the glass for training the rods and the shoots to, having them about 9 inches apart, one for the rod and one on each side for securing the shoots to, which will not cause much shade below to the trees, and the Grapes depending over the pathway not only have a fine effect, but are very useful, especially when other means of growing Grapes are limited. The shoots ought not to be nearer together than 2 feet on the same side of the rod, they being stopped one joint beyond the fruit; if no fruit at the sixth leaf, and the laterals stopped at the first leaf. A border may be prepared for the Vines either inside or outside the house as may be most convenient, the chief consideration being to have it well drained. Black Hamburgh and Foster's Seedling or Royal Muscadine are the best black and white Grapes for this purpose. Figs in pots or planted out will require copious supplies of water, as, if they become dry at the roots, a check will be given that will cause the fruit to drop. Stop all strong shoots at the sixth leaf, and any weakly ones that tend to crowding, as also needless shoots remove altogether, for crowding of the shoots, whether the trees are in pots or planted out, tends only to unfruitfulness.

PLANT HOUSES.

Greenhouse.—*Salvia splendens* and *gesneriiflora* should, if not already done, be placed out of doors, previously having been shifted into their blooming pots, and staked and tied to prevent the shoots being broken by the wind. If plunged in ashes they will require less attention in watering, and the lower leaves will be less liable to fall. *Veronica Andersoni* and *salicifolia* are among the finest of autumn-flowering plants, but to keep them sturdy and induce a free-flowering habit the plants should be plunged in coal ashes in a sunny situation and be well supplied with water, and with liquid manure when the pots are full of roots. Shift Primulas from the earliest sowings into their blooming pots—6, 7, or 8-inch, according as they are wanted, large or small, draining the pots well, and employing a compost of turfy loam

with a fourth of well-decayed manure or old cow dung, and a sixth of sand. *Cinerarias* sown early and intended for autumn flowering shift into the blooming pots (8-inch), they being well established previously in 5 or 6-inch pots, the main point in growing these plants being to shift them into larger pots before they become very much root-bound. These, as well as Primulas, should be placed on ashes in a cold frame, keeping them moist and shaded from hot sun, removing the trusses of bloom from the Primulas as they show until the middle of August. When the pots fill with roots apply liquid manure once or twice a week. Sow seed of *Cineraria* and *Primula* in a cold frame to raise plants for spring flowering. *Kalosanthes* not showing a disposition to flower should be turned outdoors in a sunny situation, and allowed to remain until early September. Those showing flower should be neatly tied, and as the heads of bloom begin to expand place the plants on ashes at the north side of a wall, and they attain a colour of flower very much superior to those retained under glass, and when fully expanded remove them to the conservatory, shading so as to prolong the bloom.

Hardwooded plants that were potted in spring will now have filled the pots with roots, and should have a shift into larger pots—i.e., such free-rooting plants as *Polygalas*, *Acacias*, *Adenandras*, *Boronias*, *Darwinia* (*Genetyllis*) *tulipifera*, *Eriostemons*, *Pimelea*, *Statice*, *Leschenaultias*, &c.; and there must be no delay in performing it, or the plants will not have time to become well established before autumn. The size of the shift will be determined by the state of the roots, yet the shift at this time only must be moderate, so as to ensure the well filling of the soil with roots before winter, as if it be unoccupied there is great danger of its becoming sour. Between a 2-inch and 4-inch shift will be ample. Shade from bright sun for a fortnight to three weeks after potting, admitting air moderately, and maintain a moist atmosphere by sprinkling the floors frequently. Good fibrous peat is the only suitable compost for potting these plants, except clean white sand, which if sharp—i.e., free from dusty particles—and gritty all the better, adding about a fifth more or less according to the nature of the peat, and allow rather more space for watering between the rim of the pot and the soil, potting firmly. *Pimeleas* and *Boronias* after flowering should have a good syringing, and be placed where they can be kept somewhat closer, syringing every evening lightly to keep down red spider.

Azaleas that flowered early and have been potted and encouraged to make growth some time ago will not require more than very slight shade—a thin moveable material that can be withdrawn in all but the brightest weather. Any weakly plants making growth may have liquid manure at every alternate watering. Plants that flowered late should have the seed pods removed, keeping rather close, moist, and shaded, encouraged to make a good growth speedily. Shading, however, should only be resorted to to prevent the leaves from being checked in development, giving otherwise all the light possible without direct exposure to hot sun. Any plants of *Genistas*, *Correas*, *Acacias*, *Libonias*, *Monochæstums*, *Daphnes*, &c., intended for winter blooming should have every encouragement to make a good growth; and if any require more pot room it must be given at once, and if red spider appear keep it under by frequent and copious syringings. *Epacris* and *Heaths* for winter flowering will now be making free growth and should be kept in a light position, admitting air freely in the early part of the day, closing rather early in the evening and syringing overhead. *Fuchsias* that have flowered early may now be placed out of doors for a few weeks in a sheltered situation, all flowers and seed pods being picked off and the shoots then cut back about half, strong ones a third of their length; and when the fresh shoots are 1 to 2 inches long the plants, if moved into pots a size larger and placed under glass, will flower well in autumn on into the winter.

TRADE CATALOGUE RECEIVED.

T. W. Hellewell, Brighouse, Yorkshire.—*Prospectus of New System of Glazing.*

TO CORRESPONDENTS.

. All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*W. Phillips*).—"The Garden Manual," which you can have from our office if you enclose twenty postage stamps with your address.

SANDY PRAT SOIL (*Ash, Surrey*).—A heavy application of clay is your only mode of improving the staple of the soil. Mulching the surface over the roots of the crops would be a temporary safeguard for them.

ROSES (R. C. Croydon).—The largest, Paul Neyron; the sweetest, Provins Cabbage, La France, Bessie Johnson; the earliest, Old Monthly China; latest, Gloire de Dijon. The above are our own experience, but we shall be obliged by any reader stating his experience and where.

GRAPES DISEASED (Bristol).—They are severely attacked by the spot. The roots are torpid, and probably would be benefited by a liberal supply of weak liquid manure. Of the plants, No. 1 is *Habrothamnus elegans*. The others are florists' varieties, which are too numerous to be identified from single blooms.

FUNNEL-SHAPED LEAF (L. Hanlow).—It is a freak of Nature, and, like most of her freaks, inexplicable.

TRANSPLANTING ROSES (L. H.).—Your Roses must not be taken up before October, and then it is well to let the condition of the growth be your guide, for in a mild genial autumn the growth will be in activity somewhat later than in one of early frosts and low temperature. If it is possible to defer the planting till November do so, that month being the best of all the twelve for the work.

BALSAM CULTURE (Idem).—Expose your plants fully to the action of light and air, taking especial care not to crowd them together. Give them plenty of liquid manure. Pick off flower buds as they appear until the plants are as large as you desire, then let them flower, but do not cripple or retard any of the growth by pinching, for the natural habit of the Balsams is to become bushy and symmetrical; if it fails to do so it is owing to crowding or neglect.

MANAGEMENT OF VINERIES AND PEACH HOUSES (W. H.).—You cannot have more practical information nor more seasonable than that contained in "Work for the Week" published in the Journal. A small work, "Indoor Gardening," published at this office, post free for 1s. 7½d., also contains directions of culture for fruits under glass.

FRAGRANT ROSES (Amateur).—La France, Devonensis, Maréchal Niel, Charles Lefebvre, Louis Van Houtte, Gloire de Dijon, Alfred Colomb, Bessie Johnson, Abel Grand, Sénateur Vaisse, and Camille Bernardin are all highly fragrant and well adapted for exhibition purposes.

MELON HOUSES (H. E. M.).—Melons may be successfully grown in a house 10 feet wide—either a lean-to or a half-span. Two rows of 4-inch pipes for affording top heat will be sufficient unless you require the fruit very early. The same extent of piping is also requisite for affording bottom heat.

HORTUS SIOCUS (Mr. M. J. Teedall).—Sheets of blotting paper in a portfolio form a good mode of preserving wild flowers placed between the sheets and pressed.

NAMES OF FRUIT (Comnaught Subscriber).—1, Joo-c-o-sot; 2, Not known.

NAMES OF PLANTS (A. B.).—Neither of the specimens sent was *Lycaste Skinneri*. They are probably *L. aromatica* and *L. Deppel*. (*Un Garçon*).—Specimens much withered. 1, *Cineraria maritima*; 2, *Sedum Sieboldii*; 3, *Ceanothus rigidus*. (*M. R. D.*).—*Arisæma Murrayi*, *Grah.* (*Bot. Mag.*, t. 4388). (*Dr. Mackenzie*).—*Cladrastis lutea* (*Virgilia tinctoria*). (*An Irish Subscriber*).—You surely cannot expect us to name your Grasses from the specimens sent? (*E. H.*).—*Thalictrum aquilegifolium*. (*J. M. L.*).—We cannot name plants from leaves only.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HAY MAKING (FIELD HAY).—Continued.

IN preparing a stand or steddle to build ricks of hay upon, it is a good plan to use some stout faggots, so that there may always be a free circulation of air passing through them at all times after the ricks are made. For want of these, or some such materials to make the floor of a rick, we have seen large quantities of hay seriously injured by the damp rising into the rick during the winter months, and this is especially the case in low situations. It is also a good method of protecting the bottom of the rick to make a trench about 12 inches wide and 9 inches deep all round to take away freely all water which drips from the eaves of the rick. Some method of protecting the hay which is being stacked is requisite, otherwise in the event of a sudden thunderstorm serious damage may occur. We consider the outlay for the purchase of a large sailcloth and poles is money well spent, and if the poles are erected so that at short notice the covering cloth may be available, no hay need be damaged whilst the rick is building. The size and shape of the ricks is a matter of some importance; for although large ricks to contain thirty or forty tons may be best for the hay, there being less outside and waste, yet, when the season is catching, twenty tons are enough for one rick, as it is more quickly secured.

In the choice of a mowing machine several important points must be observed—viz., the size of the ridges upon which the grass is growing, for where the land is level those implements which took the first and second prizes last year at the annual meeting of the Royal Agricultural Society of England, are made by Samuelson and Woods respectively, must be considered the best up to the present time; but where the land lies in very small high-backed ridges other implements may be better. For

instance, it is stated that the mowers made by Burgess & Key will make the best work where the land is uneven caused by deep land furrows, but even to effect this the machine must be driven across the ridges in order that as little grass as possible may be left uncut in the furrows. In the former part of this article we referred to the making of hay principally in dry weather, recommending the continual exposure and constant moving of the hay by the tedding machine as the best means of securing the best quality. In wet and stormy seasons we advocate a plan nearly the reverse, for after the grass is cut, and the barometer indicates wet weather, we advise that the swathes should not be turned for several days after cutting. It is here and under these circumstances that hand labour must have the preference, and consequently turning the swathe without spreading abroad is the great essential to be observed, for when the swathe is merely turned some portion of the hay may retain its colour, although the outsides of the swathes may be washed and bleached. The next point to be considered is whether it is advisable to put the hay into small cocks, or pooks, after the second turning of the swathe. We think this matter must be considered a question of climate, for in the northern counties and Scotland it will be probably best to make small pooks first and then increase their size as the hay proceeds towards maturity. In the sunny south and eastern counties we consider it best to allow the hay to remain in swathe, and thus make available the first day of bright sun or windy weather for carting, and only by pooking the hay as fast as it can be carried to the stack.

The size of the ricks may be determined according to circumstances, such as the state of the hay, whether in first-rate condition or damaged by wet weather, also if it is required for sale or consumption on the home farm, and again if in an exposed situation. When hay is got up in fine weather and sufficiently made the ricks may be made large, but especially they may be of large size when the hay is intended for sale. In such a case, now we have the use of the elevator, the rick may be made higher, as there will be less outside and waste, and it will take less straw for thatching in proportion to the size of the rick. Should the hay have suffered injury from wet weather and the season be catching at the time of building the ricks a moderate size will be best, because they may be made and topped up safe on the day of making. The observations just made refer to ricks made long and narrow, which is probably the best shape under ordinary management, but we have sometimes made them round, and have often seen them in some of the midland or western counties of that shape. We see nothing to object to in making them in that form, particularly in exposed situations near the coast and on very high lands, the chief advantage being that round ricks take less thatch, which is not so likely to be blown off as the wind plays round the ricks, instead of striking it on broadside, as in the case of oblong ricks; besides which there is less outside and waste as compared with long narrow ricks. The only valid objection we have ever heard is that when the hay is required for sale it does not truss out for sale so well. This objection, however, entirely disappears when required for consumption on the home farm.

When the weather is very fine and the hay uninjured, with rain threatening, it is sometimes a good plan to secure the hay and get it into rick rather than trust it another day, although we may be aware that it is not made quite enough to prevent excessive heating. In this case there are several ways of proceeding, some applying layers of good sweet barley or oat straw over the rick whilst making, say ten or twelve hundredweight of straw to every two or three tons of hay. This will check the heat, and likewise improve the value of the straw as fodder; and in making ricks for home consumption there will always be a good use found for the straw in winter time, either for feeding the team horses or for fattening bullocks. The straw in such cases comes out of the rick with a fragrant aroma, almost equally attractive to the animals as the hay with which it was mixed. There is another method which we have adopted when we are uncertain as to the over-

heating of the rick. We fill a common sack full of hay trod in hard, and in the act of making the rick the sack is lifted up a little as every load is added, taking care to tread the hay firm round the outside of the sack, and if the sack is started from the faggots at the bottom of the rick the chimney which will be formed will give a free current of air through the faggots and up the chimney, and enable any excessive heat to escape without injuring the hay. There is yet another way to anticipate and provide for excessive heating of hay—that is, turn the rick over on to another stand at the end of five or six days, and in order to ascertain the state of the hay we use an iron rod as a probe about 12 feet long with a barb at the end, so that when introduced into the hay it will bring out a little piece and show you the exact condition of the hay. Even then it cannot always be ascertained as to the necessity of turning the rick; we therefore allow the probe to remain in the rick about six hours, and if the probe on being withdrawn cannot be held with the naked hand without extreme pain similar to burning, we may feel assured that the rick must be turned or receive serious damage by charring. In such a case the hay is no use for sale, and is damaged for home consumption. One of the best ricks of Dutch clover hay we ever had was found to be overheating at the end of five days, we then turned it over and reformed it into another rick alongside. We have done this with good results, and should never hesitate when the rick is too hot. We recollect an old farmer of Somersetshire stating that he did not consider you ever reaped the full profit and feeding value of hay unless the rick was turned twice. This is, however, carrying the matter too far, still it goes to show that it is preferred to overheating. When hay has received serious damage by a succession of rainy weather it becomes a question when stacking the hay whether any and what means can be resorted to with the view of improving and making the hay more palatable to the stock. We used to apply salt, but that is sometimes a very dangerous matter, for if there is the slightest wet or damp in the hay when carried to rick the whole will prove a mouldy mass such as no cattle will eat; we therefore recommend materials formed into spice and dredged over the rick, a portion to every load of hay. There is, however, a spice for flavouring damaged hay sold by Messrs. Simpson & Co., 54, Chiswell Street, London, which is well spoken of by those who have used it, and it costs about 2s. or 2s. 6d. per ton of hay. There are, however, several mixtures of spice as recommended for the purpose, but none more effectual than this condiment that we know of.

WORK ON THE HOME FARM.

Horse Labour.—In many instances the horse labour of the home farm is somewhat in arrear, owing to the succession of rains in part of April, all through May, and in fact up to the present period in some localities. In all those districts where these rains have prevailed it has been very difficult to obtain a good season for drilling the mangold and Swedish turnips, especially where the land was foul with couch or water grass. This is very much the case this year, particularly where the land is farmed upon the four-course rotation, because if any of the small roots of couch are left when the land is sown with Lent corn and at the same time seeded with clover these small pieces of grass will increase to an enormous extent before the land comes in course for fallow again. There are twenty-eight months when the wheat is sown out of clover lea which elapse before anything can be done towards cleaning the land; and strictly speaking this circumstance is one of great disadvantage in the four-lain system, especially where the land is well farmed, for the higher land is manured the more the couch will flourish and extend, particularly in sand or sandy loam soils.

The horses are yet engaged in cultivating for roots, and at every opportunity they will when the weather is favourable be employed the field hay to stack. The odd horse, or rather which is often found to answer the better purpose, is the employment of a good strong donkey or upstanding mule in the hoeing between the rows of mangolds, cabbages, and potatoes. The advantage of the use of a mule we have found to be that in horse-hoeing work it does not step so wide as a horse, and therefore does not tread the roots so much, and this is very desirable when common turnips or potatoes are grown close in the rows. The odd work of the farm can never be cheaper or better done than with a strong well-broken mule. These animals are very strong, scarcely ever suffering from many complaints and disorders to which horses are liable. They are, however, costly to purchase if you can obtain an animal of the right size and stamp with sufficient power. We have seen them from 18 to 14 hands in height, and they will then on level ground draw a ton weight without difficulty; again, these animals will endure a longer day's work than horses, and are especially adapted for odd work, being ready at all calls.

Not only the horse-hoeing of potatoes will be going on now, but also earthing-up or hilling. This should be done with the double mould-board plough or double turnfurrow attached to the horse hoe. We find sometimes it is a good plan to sow 1 lb. of greystone turnip seed per acre previous to the operation of hilling or earthing-up, which work lifts and buries the turnip seed on the ridges most effectively. The object of this system is to keep down

the weeds and produce a crop of cattle food in addition. When the potato haulm is struck down by disease (which it has been more or less upon some farms ever since the year 1845), the turnip plants having before made little or no progress, then make a rapid growth, and quite prevent weeds from increasing, which they certainly would do upon well-manured land, and before we resorted to this plan of sowing turnips we have often been obliged to mow the weeds or handpull them at great expense before we could dig the potato crop. It should, however, be remembered that in case the potato crop goes on to full maturity without the decay of the haulm that the turnips will have no chance to come to a crop, but it is only the loss of 1 lb. of turnip seed per acre, and it is therefore well to be prepared for the failure of potatoes at so small a cost.

Hand Labour will now consist of hoeing mangold, potatoes, cabbage, and such like crops; also mowing in the meadows, for we often find that the mowing machine is not always available, and particularly this is the case in water meadows or park-like pastures encumbered with timber. At intervals men will be employed by hedge trimming, also preparing ashes or chalk for drilling with the turnips, which are yet to be sown. Cabbage planting will also be going on, in which work the women will assist the men by carrying and laying down the plants.

The shepherd will now be required to use his utmost vigilance in order to detect those cases where before the sheep are shorn it is often found that the long wool is fly-blown and maggots produced. Many modes of destroying the maggots are in use, but we know of nothing so good as oil to apply to the part where the maggots have existed, particularly where the skin has been broken, as the oil will not only serve to heal the abraded skin, but will effectually prevent the fly striking again, as flies always avoid oil or oily substances. The application of mercurial preparations are sometimes used, but it is very objectionable, as it hardens and as it were ossifies the cuticle. The shepherd's care is often particularly requisite in washing the sheep before shearing, and in a running brook or river where the water is deep it is desirable not only to have no more than four or five sheep in the water at one time, but even then the man in attendance should take particular care that every animal should be passed to the washer in its turn, otherwise the sheep often sustain injury from being too long in the water.

THE POULTRY CLUB.

It is an acknowledged fact that undertakings which are started in a quiet and unpretending fashion, are generally destined to a greater amount of success than those which are heralded by a loud flourish of trumpets. If this be true we may augur well for the future of the Poultry Club. It is now towards a year and a half since the formation of some such society was first advocated in these columns. The idea was at once eagerly taken up by many correspondents, but, as is often the case, many of those who would write and talk fluently on the subject were not equally ready to give any practical assistance in the matter. We well know that the difficulties in starting clubs are very great. Those who have had any experience in them are aware that a number of formalities, which at the time seem unnecessary if not absurd, have to be gone through to avoid future difficulties and misunderstandings. For a time we feared that these had proved too great, and that in spite of the strong wish of a large body of fanciers to unite themselves in some way for mutual protection and to protest against certain scandals to which we will not revert, the scheme had collapsed, simply from the impossibility of deciding in what way they should best do so. Such, we are glad to find, has not been the case. We have now before us the list of the Poultry Club fully and formally constituted. It has officers and a Committee which must show it to be no party concern, and to begin with a list of 180 members, whose numbers are, we hear, being constantly increased. A good deal is already achieved. A body of fanciers, whose names must have influence, have formally allied themselves for the furtherance of poultry breeding, and specially, regardless of a good deal of opposition, to assert that they will do all in their power to prevent any sort of fraud in the exhibition of poultry. This, of course, is only a beginning, and a great deal of tact and judgment will be necessary for the Club to carry out at once gently and decisively the objects it has in view; still it is something that such a start has been made, and that without any of the ordinary puffing and advertising with which the crude formation of one or two societies has been announced, and without any pledges as to the exact scope of its future action. We make no apology for returning to what seem to us the most obvious and practical measures for the Club to attempt, because it is now presented to us in a definitely constituted form.

When any poultry or ornithological club is formed, generally the first thought of the members is to get up a show. Now we strongly hope, and have very good reason to believe, that the Committee of the Poultry Club have no such intention. Poultry shows have done, and will we trust continue to do, a great deal of good towards awakening interest in poultry breeding and improving the breeds of poultry, but they are already far too numerous; and supposing that the Committee of the Poultry Club, which is most unlikely, had the time to carry out a show, the financial

question is always a risk. The holding, too, of a single show on the best principles would not be likely to have very great influence on the morality of shows in general. Where the Club can have, and we believe will have, legitimate influence is in the improvement of existing shows. Its Committee has been instructed to draw up from time to time, as circumstances may require, rules for the good management of shows, under which committees are invited to put them. The first scheme of regulations is before us, and gives no uncertain sound. Exception may be taken to some of their wording and detail, which we know will soon be, if it has not already been, amended; but their general drift is that fraudulent practices, or the appearance of them, are to be carefully inquired into, and that if proved against an exhibitor they shall not be hushed up, but visited with the merited penalty of forfeiture of all prizes and exclusion from further shows.

We already see that the Hemel Hempstead Show—which seems started on the soundest financial principles, and which is therefore almost certain to be a success—is advertised to be held under these regulations, and we hear of other committees being ready to adopt them. This is encouraging, and we do trust that it will soon be shown, as we have always thought, that the dishonest exhibitors are very few. From the unfortunate condonation of the tricks of one or two of their numbers on notorious occasions public attention was so much attracted to them that an erroneous impression got abroad that poultry fancying must necessarily be connected with fraud. The sooner this is dispelled the better. We believe nothing but this vigorous effort of a large number of fanciers would have dispelled it, so firmly rooted it seemed in the minds of many people. There is something more, however, to be done than the framing of rules against fraud, or even their adoption by committees; they must also be carried out by them and by judges.

We rejoice to see the names of two judges whose experience is immense, and whose capability is universally recognised, on the list of the Poultry Club, as being evidence that they feel that through it their hands will be strengthened. In many a schedule we have read strongly worded rules against fraudulent practices, but when their application was required they always seemed to break down and the offender to escape. Now, we cannot and do not believe that this has been often or generally the fault of the judges. For the most part we lay these scandals to the charge of committees, fearful of offending an influential exhibitor whose entries would affect the balance sheet, or desirous of screening local exhibitors or friends. Now, if it can be managed for the odium of any necessary disqualification to be laid ultimately on the backs of a body too remote and impartial to care the least about it a great burden will have been taken off a judge's shoulders. We do not here touch upon the delicate question of one or two "improvements" such as the shaving of Spanish faces, which have become almost recognised; they will probably come under the notice of the Club. But where some undoubted trickery, such as plucking of hocks or carving of combs, is manifest, if a committee can boldly say, "We have accepted these rules, every exhibitor can read them, we are therefore bound to carry them out," we believe that judges will find themselves in a much more independent position than heretofore, and that a great stride will have been taken in the direction of suppressing fraud.—C.

THIS SPRING'S POULTRY REARING.

ON reading R. Teague's system in your number of June 13th one is surprised to find that any of his chickens survive such a pickling outside and in as he gives with carbolic acid, lime, camphor, pepper, and sulphur. Several years' experience with an average yearly rearing of two hundred chickens leads the writer to urge the necessity of plain living without condiments. Chemicals lose their efficacy if given as food, and condiments are best avoided when chickens are in ordinary good health.

To notice R. Teague's points *seriatim*. On ordinary dry soils coops without bottoms will be found healthier than boarded coops. A mixture of road grit and ashes may be used with advantage without quicklime, but the coops should be moved daily, or at the extreme, with R. Teague's mixture, every other day. The next point, water, is a fruitful source of evils if not changed several times daily and always kept shaded from the sun. Filthy water warmed by the sun breeds much disease. Camphor may be used as a remedy but not as a preventive. The writer has found the following food system very satisfactory. First day, custard of egg beaten up with a very little milk and set with heat. Cut groats are added until the fourth day, when the custard is ceased and boiled rice substituted. Barleymeal, oatmeal, and maize meal are gradually introduced with the boiled rice in increasing ratios. At the tenth day whole groats are used and broken rice not cooked. Wheat and buckwheat are gradually given in small quantities. From the very commencement a variety of green food is given, as, although grass is unequalled, we find a constant change gives good results and repays all trouble. Minced onion is a grand tonic and is often given both in the meal and otherwise. Mustard, cress, lettuce, or young cabbage shredded, and at intervals small quantities of boiled potatoes, are used, but not as

regular food. We feed as often as possible, say every two hours. Thus in the third week we give a morning meal of boiled rice and meal mixed with shredded onion; at 9 A.M. whole groats and lettuce; at 11 A.M. or noon broken rice and some green food; at 1 P.M. boiled rice or crust of bread soaked and squeezed dry; at 3 P.M. boiled rice and meal; at 5 P.M. whole groats and cress or lettuce, and a few grains of wheat or bran.

By experience we find that cleanliness, dry quarters, and as much change as possible of both food and locality, are the best preventives of disease. The extra trouble involved is very trifling, as a careful orderly system is in reality much easier to apply than a disorderly careless one. As to any extra expense, it will not amount to 6d. per head at the very outside, and this, it will be allowed, is a bagatelle as regards pure-bred stock.—C. B.

If the result of Mr. Teague's spring poultry-rearing has been the general experience this year I must consider myself particularly fortunate in my small way. It is some years since I kept fowls, but this spring I placed a sitting of eleven Cochins eggs under one Brahma hen, and ten Golden-pencilled Hamburgs under another. The former brought out nine chicks and the latter also nine, all strong and healthy. I lost one of each brood during the late damp weather, and a cat took one of the Hamburgs, but all the rest are thriving wonderfully. I have always given them a dry case to sleep in and a clover run, and have fed them on broken grits, sopped bread or crumbs, worms, and occasionally a little hemp seed.—J. S. DISMORE, *Gravesend*.

INCUBATORS.

A CORRESPONDENT, "S. W.," having applied to us for information on incubators, we approach the subject with trepidation, having burnt our fingers with them. We had difficulty in regulating the heat except where we had gas; where we had that we had little difficulty. We have never had any trouble in hatching. That may be done in the kitchen oven if it be filled with dry sand and the heat kept up. It is when the chicks are hatched the trouble begins. They lack the assiduous care of the hen during the first few days or hours of existence. This cannot be over-estimated. It is the lack of this that causes crooked toes, wry necks, and deformed backs. Monstrous joints are the result of chill afterwards. The real use of incubators is to hatch birds (Pheasants, &c.) during the heat of summer when there is no fear of cold. They are very useful when hatching on a large scale is necessary if a certain number be divided, half put in the incubator, the remainder under hens. They all come off at the same time, and may be all given to the hens.

We had experience of them many years ago when fancy had nothing to do with it, but the chicks were hatched, reared, and sent to market as an article of trade. If nineteen dozens of chickens were put up, eighteen naturally hatched and reared and one dozen produced by the incubator, a tyro could detect the latter from their deformities. They looked when alive like workhouse children—stunted in growth, with large heads and cute faces, large joints and small limbs. This applies to chickens hatched when the season and weather are unfavourable for rearing. They are being much tried in France. That most generally used is one patented by Messrs. Rouillier & Arnould of Gambais. Its principle is that of hot water changed sufficiently often to maintain the necessary temperature. Its price varies from £6 to £12.

VARIETIES.

A COMMITTEE meeting of the Poultry Club was held at Oxford during the show meeting. There were present the Hon. and Rev. F. G. Dutton, T. C. Burnell, and A. Darby. The following elections into the Society were made. Members—H. T. Bailey, Rose-dale, Tenbury, and Edward Hewitt, Sparkbrook. Associate Members—F. Parlett and T. J. Saltmarsh, Chelmsford; Mrs. Gordon, Salcombe, Sidmouth; Mrs. Lang, Knowle, Sidmouth; M. F. Smyth, Londonderry; T. A. Bond, Londonderry; P. Ogilvie, Hambledon, Hants; Miss M. C. Orr, Ecclesgreig, Montrose; and Miss C. E. Palmer, The Yews, Odiham.

THE English Jurors for the Agricultural section of the Paris Exhibition were entertained on the evening of the 12th at a magnificent banquet by M. Tesserine de Bort, the French Minister of Agriculture and Finance. Almost all the English Jurors for live stock and a few exhibitors were present. The salons of the Minister were afterwards thrown open, and M. Tesserine de Bort had a large assembly. It was curious and interesting to observe amongst decorated Senators and Deputies some of the most successful herdsmen in their quaint costumes.

WE regret to learn that the beautiful Early Wood poultry yard and pigeonries will not long be visible, and that those who wish to see them must do so soon. The lease of the place terminates at Michaelmas, and Mr. Cresswell will in consequence probably be obliged to part with a large part of his stock.

THE British Bee-keepers' Association will hold their fourth Great Exhibition of bees and their produce, hives and bee furni-

ture, and honey fair, at the Royal Horticultural Society's Gardens, South Kensington, in connection with the Society's flower show, on August 6th, 7th, and 8th, 1878. Silver and bronze medals are offered for hives of various forms, supers, bees, and liberal money prizes are offered for honey. Entries close July 27th, 1878. Rev. H. R. Peel, Abbott's Hill, Hemel Hempstead, is the Hon. Secretary, and who will thankfully receive donations for the prize fund.

DORSETSHIRE BEE-KEEPERS' ASSOCIATION.

THIS Association was established in November, 1876, by a few gentlemen interested in and practically acquainted with bee-keeping, for the purpose of introducing amongst the rural population of the county of Dorset a more humane and profitable system of apiculture. Bee-keeping has been hitherto, and is now in a great majority of cases, conducted in England on a most cruel and wasteful system. To obtain the stored-up honey ignorance knows no better than to smother the bees with brimstone and destroy and strain the honeycombs. As well might the farmer kill his sheep to get their fleeces, or the gardener fell his trees to secure the fruit. The means so adopted are wasteful in many ways. The stock is reduced, the combs are destroyed, and all the bees' labour in making them is lost. There is also great waste of material, for, be it remembered, a pound of wax, worth about 2s., costs the bees about 20 lbs. of honey to make. Again, the honey is contaminated with all the dirt of the densely crowded population, as well as crushed brood, young bees, &c., all go into the strainer that bulk may be increased; and last, not least, the inhumanity in destroying the industrious little creatures who have worked so hard for their cruel masters. To supersede this remnant of the dark ages enlightened thoughtful men have at various times designed and improved many hives and appliances, by use of which perfect command can at all times be had over the bees and their dwelling place, affording facilities for honey-gathering and removal in its natural, pure, and wholesome state without injury to the bees. The best means by which this is accomplished is by the use of what are termed "frame hives"—that is to say, hives in which the bees, instead of being allowed to fix their combs immovably to the walls of their dwelling, are forced to build the combs on moveable frames, the position and number of which can be varied at the will of the bee-master, so that he is enabled either to increase or take away from the number of bees in his hive, to notice at once when sickness or hunger is imminent, to extract the honey without destroying the combs, whereby the productive power of the stock is increased, and, in short, to perform numberless operations which could only be done with great difficulty or not at all with the old-fashioned straw skep bee hive. For details of frame hives and the operations that can be performed with them the reader is referred to the standard works on bee-keeping, and an hour or two would be well spent in perusing such books.

The English cottager is hard to move from adherence to old customs—that which his forefathers did he does. But the force of example is great, and to that the Association looks to gradually wean him from the custom of bee-slaughter and starvation; and when he finds his more enlightened neighbour acquires good and profitable stocks by means of bees formerly doomed to death, then will he begin to doubt the policy of his old ways, and perhaps improve on them.

There are few places in England where bees may not be kept with more or less profit, and it is not even necessary that their owner should have a garden—indeed it would require a very extensive garden to be large enough at all seasons to supply a single hive of bees with the desired nectar from its flowers. Not only from our flower beds do bees obtain their abundant stores, but from the myriad blooms on our forest and fruit trees, the gay luxuriance of the hedges and shrubs, and the unnumbered blossoms of our meadows and uplands—from these doth the busy bee cull the sweets we covet.

RULES AND REGULATIONS.

1. That the name of this Association be the Dorsetshire Bee-keepers' Association.
2. That its objects shall be the encouragement, improvement, and advancement of bee culture in the county, particularly as a means of bettering the condition of cottagers and the agricultural labouring classes.
3. That the officers shall consist of a President, Vice-Presidents, Secretary, Treasurer, and an acting Committee, three of whom shall form a quorum. The whole to hold office for one year and be eligible for re-election.
4. That the management of the Association shall be vested in the acting Committee, of which the Secretary and Treasurer shall be ex-officio members.
5. The annual subscription of members shall be not less than 5s., due and payable on the first day of January.
6. The Committee shall cause to be holden an annual apian exhibition at a time and place they may deem most suitable to the interests of the Association and its objects; and adopt such measures as they believe will most conduce to extend and improve a knowledge of bee-keeping so far as the funds of the Association will permit.

7. That an ordinary General Meeting shall be holden once in each year, when the officers for the ensuing year shall be elected, the accounts shall be audited, and questions of government of the Association be discussed and decided upon. An extraordinary General Meeting may be called by the acting Committee at any time, and shall be called by the Secretary within fourteen days upon receipt of a requisition signed by any ten members, stating the nature of the business for which the meeting is to be held.—(Extract from Society's Address.)

FOUR SWARMS FROM ONE STOCK.

I COMMENCED the past winter with three stocks of bees, of which I lost two, the remaining one being a strong stock in a 15-inch straw skep, and from it have issued four swarms in ten days. The first swarm came out May 28th, the second June 8th, the third June 6th, and the fourth on June 7th. The first and last are strong swarms, the second moderately strong, the third a mere handful, which has since died. I should have thought that one at least must have been a stray swarm were it not that I had positive proof to the contrary, for the three last swarms were seen leaving the hive; and although the first was not seen until it had settled, yet the condition of the stock was a sufficient indication that a swarm had issued from it.—R. CATT, *Gardener, Caterham Asylum, Surrey.*

[It is an uncommon thing for a hive to swarm four times in a season, but not an extraordinary occurrence. We hope that all the swarms will become strong stocks for another year.]

GOSSIP ABOUT BEE PASTURE.

MR. B.—Having heard, Mr. Pettigrew, that you have been on a visit to Scotland, I have come to learn what you think of bee-keeping and bee pasture there. As your visit was made in the middle of June, the season of swarming this year, you would naturally compare what came before you there with what you have been accustomed to see for many years in England.

MR. P.—Let me tell you first that I went to Carlisle near Lanark to seek health, and there I never forgot my errand, but walked about the town and rode up and down and over the parish a good deal. I was therefore able to form an opinion as to its eligibility for bee culture, but I did visit many of the bee-keepers. Those I knew forty years ago have all been swept away by the hand of time and a new race has taken their places. Two or three of the present bee-keepers spoke to me in the streets. One of them, James Somerville, told me all his hives had swarmed once and one of them twice. I ventured to make the remark that as the season is unfavourable he would do well to take no more second swarms. He then said, "I dinna ken, man, for second swarms here in 1876 rose in weight to 70, 80, and 90 lbs. each."

MR. B.—If second swarms reached that weight in 1876 the pasture there must be good.

MR. P.—Yes, it is good, and management too, but the pasturage of many other places is as good as that of Carlisle. This village stands on land 600 feet above the level of the sea. Some of the parish resting on the river Clyde (which runs through the centre of Lanarkshire) is probably 200 or 300 feet lower than the village, and the highest parts of the parish are probably 200 or 300 feet higher than the town. The soil is clayey, and the climate is cold save in the vale of the Clyde.

MR. B.—You consider the cold and ungenial climate there disadvantageous to bee-keeping?

MR. P.—Most certainly, the warmer the climate and the weather the better for bees.

MR. B.—When I read of a labouring man at Carlisle making £100 of bees in a season, and that another had realised £40 profit from nine hives, I could not avoid fancying that the pasture there is good. Has it any advantage or peculiarity over the parishes or counties surrounding it?

MR. P.—Yes; the orchards on the Clyde are probably the best in Scotland, and the best of the orchards on this river are in the parish of Carlisle on the north, or in the parishes of Lesmahago and Dalsell on the south side, all lying in the vale and on the banks of the Clyde. Magnificent and fruitful orchards they are. Many of "the banks and braes" of Carlisle parish that were covered with whins, bramble, and brushwood in my youthful days, then considered worthless—mere coverts for foxes—are now converted into fruitful gardens of great extent, which attract the attention and money of the large fruit-dealers and preserve manufacturers of Scotland. The fruits of the orchards on that part of the Clyde are sold annually by public roup or auction. The owners of the orchards arrange for the convenience of both buyers and sellers to roup them all in one day. One day is named for the gooseberries and currants; later on in the season the plums, pears, and apples are sold publicly. Strawberries have been introduced during the last few years, but hitherto they have been sold by private bargain at prices ranging between £100 and £150 per acre.

MR. B.—Do bees care for strawberry flowers?

MR. P.—No; but plum, gooseberry, cherry, pear, raspberry, and

apple blossoms yield honey in great quantity of the finest quality. The bee-keepers of Carlisle know this well, and therefore remove their hives to the orchards in spring, and leave them there till the swarming season. Fruit blossom being amongst our early flowers are of most advantage to hives that are well managed.

MR. B.—What do you mean?

MR. P.—If hives are well filled with bees in autumn their effective force in spring is great and able to store up much honey, while hives weak in bees have an uphill battle to fight for continued existence. In weak hives almost all the vital forces of the bees are required to attend to and hatch brood.

MR. B.—All you say stands to reason, though I have never seen it in that light before. I see now that hives strong in bees in spring have virtually a longer summer than weak ones.

MR. P.—Yes, and weather permitting they store up a large quantity of excellent honey from fruit blossoms.

MR. B.—What honey flowers come in after apple blossoms?

MR. P.—Sycamore trees come into flower before apple blossoms disappear, and continue a long time in flower if the weather be not very hot. In hot seasons they run to seed rapidly. The flowers of this tree yield honey in great quantity, and the bees have little trouble in gathering it, as it literally lies on the flowers, and is clammy to the touch of human hands. In the lower parts of Carlisle parish sycamore trees may be seen here and there. The day before I left Carlisle this time I visited the gardens of Maudslie Castle, which is well and beautifully wooded. The trees surrounding the Castle stand separate and alone. Amongst them I noticed many magnificent and lofty specimens of sycamores and limes. Beans and field mustard, both rich in honey, come in flower after sycamores, and last a long time in flower. Field mustard is the yellow weed that covers many of the corn fields of England and Scotland. Very little of this weed is seen around Manchester or in this part of Cheshire, but it abounds along the line of railway from Preston to Carlisle, and these places are 170 miles apart. It is a capital thing for bees. Beans, too, are excellent for bees, but they are not so abundant as field mustard. In some districts they are not grown at all. I saw one small field of them only in Carlisle parish, perhaps about 2 acres in extent. On going across the Clyde to visit some distant relatives in the parishes of Dalsf and Lesmahago I saw more beans growing that day than I have seen for thirty years. The land there is heavy—a yellow clay soil, in which beans are extensively cultivated. In some parts of Nottinghamshire, and perhaps elsewhere, some farmers sow their fields in autumn with beans, which help the bees much in early summer.

MR. B.—You consider that sycamores, field mustard, and beans are the principal honey plants in this country that flower between the times of apple blossom and white clover.

MR. P.—Yes; they cover the space of time you have named, and both beans and mustard last till white clover is well in flower. Often bees have mustard, beans, and clover to resort to at the same time. As mustard and beans go out of flower bramble bushes and lime trees come into flower, and thus give bees a very rich pasture in July; and as this is, generally speaking, the warmest month, hives become heavy and supers are rapidly filled. Bramble or blackberry bushes and white clover continue in flower a long time, but lime trees are soon over. After these come heather, which flowers in August and September, and which yields great harvests of honey of a strong and grouse flavour, which some people prefer.

MR. B.—You have not mentioned garden flowers, such as borage and mignonette. Are they not of some importance to bee-keepers?

MR. P.—Not much. If they were grown by the acre they would be valuable. I could name fifty plants that grow in gardens, fields, and woods that yield honey, and some that yield pollen, all waited upon by bees, but they are of comparatively little value compared with those I have mentioned. Bees like to go over the garden walls and hedges to the great reservoirs of honey—"the Lakes Superior" in the orchards, fields, and forests of Great Britain.

MR. B.—One question more. Do you think that the pasture of Carlisle parish, apart from the orchards on the Clyde, is superior to that of many other places in Scotland?

MR. P.—No. The greater part of Lanarkshire, Ayrshire, and Renfrewshire is in my opinion equal to Carlisle. Other parts of Scotland I do not know much about. In returning to England I could not help thinking the country around Carlisle, Penrith, Kendal, and Lancaster is somewhat like that of Carlisle from a bee-keeper's point of view.—A. PETTIGREW.

OUR LETTER BOX.

PREVENTION OF GAPS (Ayrman).—High feeding and plenty of green food, especially lettuce leaves, are the most effective treatment.

QUAILS (G. H. G.).—The Quails now brought over are birds of passage. They come to Europe to breed, and are caught in large numbers in Egypt on the way across. The first land they make in Europe is in Sicily, where they fall exhausted by thousands. Formerly the largest part of the bishop's income was derived from the sale of them. They come in immense numbers to France, Italy, Belgium, but they do not remain. They leave in the early autumn. They do not come to England or Ireland, yet there are Quails all the year round in both countries. They are found daily by sportsmen in Ireland and form part of many bags. They are found all the year round in

Cambridgeshire in sufficient numbers to be sent up by dozens in the winter months. They are also found in parts of Hampshire, and besides of them are not uncommon. Almost all other Quails will breed in confinement, these they are subject to disease of the eyes and suffer from parasites.

HIGH-COLOURED PLUMAGE OF CANARIES (A. K. C.).—To one egg boiled hard and pressed through a small sieve with a fine-wired mesh add a teaspoonful of cayenne pepper, which should be well mixed with the egg. Through the same sieve grate a biscuit—one about double the size of a crown piece. This latter operation will clear the meshes of all egg adhering to them. Mix the three ingredients together in a basin. Huntley and Palmer's tea biscuits are well adapted for use. Feed your birds twice a day with the food in such quantity that the food tin or earthen vessel may be continually supplied. Commence with the cayenne diet before your birds have passed the age of eight weeks, and continue the same until your birds have cast the whole of their nest feathers. During the moulting process, which will extend over another eight weeks, discontinue the use of seed if you wish to attain very high-coloured plumage in your birds. The purest and highest-coloured pepper is best. Avoid the brown pepper, and do not give green food, which will mar the effect of the pepper. With the cayenne diet the feet of the birds become more clogged with dirt than when seed is used, therefore freely use sharp grit sand upon the cage bottoms or slides. If the perches of the cages become soiled wash or scrape them.

CHANGING HIVES (B. A. White).—Drive the bees out of the old stock hive into the bar-frame hive as soon as you can do so conveniently, leaving the bar-frame on the stand of the old one; and if the first swarm is close beside the old one both lots could be driven and then united in the bar-frame hive, though it is not good management to drive bees from young combs so full of brood as those of your first swarm. If they remain separate for the time being feed the bees from the old stock as soon as these are hived in the bar-frame.

REMARKS.

- 19th.—Fine morning, heavy rain between 12.30 and 2.30; fine and sunny afterwards.
 20th.—Very hazy morning, fine and warm afternoon and evening; bright starlight night.
 21st.—Warm sunny day, a little cloudy at intervals; very fine evening.
 22nd.—Bright sunny morning, cloudy afternoon; fine evening.
 23rd.—Misty close morning with very heavy clouds. Thunder was first heard about 12.30 P.M., and lightning seen about 1; slight rain began at 1.32, it became heavy at 1.40, and from 1.44 to 2.12, or in twenty-eight minutes, upwards of 2 inches fell. There was a lull from that time until 2.46, when a second rain began, which only lasted sixteen minutes, but yielded 0.86 inch. The total fall was 3.28 inches in an hour and a half, by far the largest amount ever registered in the neighbourhood of London in so short a time.
 24th.—Very fine warm day; beautiful starlight night.
 25th.—Very hot, but rather dull and hardly any breeze.
 Temperature a good deal higher than last week. Last two days very hot and rather close.—G. J. SYMONS.

COVENT GARDEN MARKET.—JUNE 26.

THE late warm weather has made a great improvement in the supply of Strawberries, and this week will see the commencement of the outdoor fruit season, some good Kent Cherries being to hand, and Currants promised before the end of the week. Trade good.
